LEGAL NOTES AND COMMENTS*

The Question of Practice in Negligence Cases

It is our purpose generally to treat questions in these columns aside from questions of practice, but a recent decision in our New York courts, under the Code of Civil Procedure (which has been substantially adopted now in many other States), is of so practical a character that we believe the loss departments, both in this jurisdiction and outside of it, will be interested.

Ordinarily, when the plaintiff's case is weak and the presiding justice believes that the complaint should be dismissed or the jury directed to bring a verdict for the defendant, he makes that ruling without submitting the case to the jury.

If, in the opinion of the appellate tribunal, he has made a mistake, then all the labor, expense and trouble of a new trial results, even though the jury upon the first trial was convinced, as the judge was, that there was no case for the plaintiff, and therefore would have rendered a verdict settling the controversy on the questions of fact forever.

Time was, when this was not the practice, and when a judge allowed a case to go to the jury, in many instances, with a settled intention in his own mind to set the verdict aside should it be in favor of the plaintiff, and grant a new trial on the ground that the evidence did not warrant the verdict. Thus, if the jury found a verdict in favor of the defendant, there was no new trial, even though the judge might have erred in his opinion that the case never should have been submitted to a jury and that the defendant was entitled to a direction of a verdict.

But when the appellate courts decided that it was the judge's *duty* to dismiss the complaint, or direct a verdict at the close of the evidence, and before submitting the case to the jury, *in every case* where he would be compelled to set aside a verdict in favor of the plaintiff, and to grant a new trial, this was necessarily abandoned by the judges, especially as it necessitated their going on record as having committed error in not dismissing the complaint or directing a verdict in the first instance.

The recent case which is the occasion of this article is that of Sullivan vs. the Metropolitan Street Railway Company, decided in the February term (37 App. Div., 491). There, at the close of the evidence, a motion was made for the direction of a verdict, and instead of deciding the motion *instanter,* the court, *pending the decision of the motion,* submitted to the jury four questions of fact, which were raised by the pleadings, in accordance with the provisions of section 1187 of the Code of Civil Procedure. The first three questions relate respectively to the absence of contributory negligence of the plaintiff, the presence of negligence of the defendant, and the amount of the plaintiff's damages. The fourth question was a special question as to whether the car was at a standstill when the plaintiff attempted to get upon it. The jury returned answers to the question which entitled the plaintiff to a judgment in a substantial amount; but the judge ignored their findings, and, granting the motion which he had taken under advisement, directed a general verdict for the defendant.

When this matter came before the Appellate Division, objection was made to the practice pursued by the court, but the court was upheld in that regard and the practice was approved, and the Appellate Division held that this practice would, ordinarily, allow them to direct judgment to be entered in accordance with the findings of the jury in favor of the plaintiff for the amount found, and so the necessity of a new trial would be avoided. In the particular case under consideration a new trial had to be ordered on another ground, because material evidence offered by the defendant company was rejected, to its prejudice. This evidence not having been before the jury, the defendant was entitled to a new trial.

It will be noted that this practice accomplishes at least three results, which cannot be obtained by the dismissal of the complaint or a direction of a verdict in favor of the defendant at the close of the evidence and before the case goes to the jury.

First, it gives both sides a chance to have the facts passed upon by a jury; and if in favor of the defendant the litigation is ended, unless there be valid exceptions.

Second, it gives the appellate tribunal a chance to direct a judgment in favor of the plaintiff, if it is found that the court erred in directing a general verdict for the defendant.

Third, in case the jury disagrees, the judge retains the power to direct a verdict or to dismiss the complaint upon the motion, which he has held in advisement, while the jury has been deliberating.

This last is a *desideratum,* since, in an ordinary case where a jury disagrees, both sides seem remediless under the present practice; for no motion will be entertained for a reconsideration of the ruling that may have been made upon the trial for the direction of a verdict or a dismissal of the complaint. A new trial, with all its expense and delay, must be accepted by both sides as the inevitable result of the mistrial.

The submission of special questions to the jury also simplifies the work of the Appellate Court, and may enable them to affirm a judgment when, under the usual practice, they would be compelled to order a new trial.

There are other advantages which, together with what we have already stated, ought to make the practice followed in the Sullivan case popular with the courts in lessening their labors, as well as with the bar. To the street railway company it would appear to be advantageous, in that it decreases the expense of litigation, and will oftentimes save them from a second trial and its accompanying inconvenience. H.

* Communications relating to this department may be addressed to the Editors, Johnston Building, 30 Broad Street, New York.

CHARTERS, ORDINANCES, FRANCHISES, ETC.

ILLINOIS.—Street Improvement—Assessments—Liability of Street Railroads—Ordinance.

An ordinance in consideration of the acceptance of which the rights of a street railroad company were extended, providing that it shall, "as respects the filling, grading, paving and otherwise improving and repairing the streets * * * on which it has constructed its railways, * * * fill, grade, pave and keep in good repair" a certain number of feet in width of the streets, in accordance with such ordinances as the city council may pass respecting the same, and the same shall be done by the company "with like material, in like manner and at the same time as required as to the rest of said street," is a valid contract, exempting the company from assessment for improvements of such streets.—(West Chicago St. Ry. Co. vs. City of Chicago, 53 N. E. Rep., 112.)

LOUISIANA.—Taxation—Street Railroad Franchises—The law requiring franchises to operate street railways to be taxed according to their value makes the earning capacity of the corporation a basis for ascertaining the value at which the franchise shall be assessed, but does not exclude reference to other elements that bear directly on the question of that value.—(Const. art. 203; Act 1890, No. 106, secs. 1, 28. St. Charles St. Ry. Co. vs. Board of Assessors et al., 25 So. Rep., 90.)

NEW YORK.—Ordinances—Street Car Fenders—A provision, in an ordinance requiring safety fenders to be attached to the front platform of electric street cars, that they shall not be more than 3 ins. from the tracks, is unreasonable, in view of the liability of the height of the car above the tracks to vary according to the loads, the grades, and the curves.—(City of Brooklyn vs. Nassau Elec. R. Co., 56 N. Y. Suppl., 609.)

NEW YORK.—Joint Use of Tracks—Leased Lines—A street railway company, having a right to operate its line in a certain avenue, agreed with another company that the two should con-

struct a double track on such avenue, to be used jointly by them; each to operate as many cars over the track as it might deem proper. Held, that the latter company could not restrain the former from operating the cars of a leased line over the double track.—(Coney Island & G. Ry. Co. vs. Coney Island and B. R. Co. et al., 56 N. Y. Suppl., 508.)

NEW YORK.—Lease—What Constitutes.

1. A contract for the passage of cars over a street railroad, of which the owner otherwise holds control, is not a lease, within Laws 1890, chap. 565, sec. 78, authorizing contracts for the use of railroads, but providing that, if such a contract is a lease for more than one year, it shall not be binding, unless stockholders consent.

2. Same—Use of Road—Right of Interference—Failure to pay compensation under a contract for the use of a street railroad does not authorize intereference with the use.

3. Same—That the terminus of the right of way has been slightly changed in the actual operation of a part of a street railroad, under a contract for its use, does not impair the right to enjoin interference with the use contracted for.

4. Same—Rights of Co-Tenants—One co-tenant of a street railroad, bound not to let, sublet, assign, or convey any interest therein without the other's consent, could not convey a perpetual right to operate the cars of a third road over the common tracks, on the consent inferable from their operation for several years without complaint from the other.

5. Same—Rights of Purchase—A company which has acquired the interests of co-tenants of a street railroad may object to the exercise of an easement to which only one interest is subject.

6. Same—Estoppel—Failure of a co-tenant of a street railroad to complain at once of the use thereof by a third road, which has acquired the right from the other co-tenant only, does not give rise to any estoppel in favor of the use.

7. Same—Corporate Stock—Foreclosure—Interest of Purchaser—One who acquires stock of a street railroad company by foreclosure of a mortgage takes it free from an agreement by the former owner, a street railroad company, for a right of way for the company whose stock it purchased over a line it occupied in common with another, and to procure from its co-tenant such right of way, though such agreement was the consideration of the purchase by such former owner.—(Chapman et al. vs. Syracuse Rapid Transit Ry. Co., 56 N. Y. Suppl., 250.)

OREGON.—Receivers—Liens—Priority.

1. Since a heater, furnished to an electric railroad company after a test showing that it would save a certain sum per month in fuel, was not necessary to keep the company in operation, the seller has no preferred claim for payment out of the receipts of the company after it goes into the hands of a receiver.

2. The fact that a heater furnished to an electric railway company before its insolvency has already earned a sum equal to the agreed consideration, by effecting a saving in fuel, does not give the seller a preferred claim for payment out of the receipts of the company.—(McCormack vs. Salem Consol. St. Ry. Co., 56 Pac. Rep., 518.)

RHODE ISLAND.—Franchise—Fare—Municipal Contracts—Right to Enforce—Test Cases.

1. Where a town granted a franchise to a street railroad company, the contract stipulating that the fare between any two points on its lines should not exceed five cents, the grantee waived its right to charge more as successor of another company whose charter allowed it to charge ten cents, under which charter the grantee had established a fare of five cents for a continuous ride.

2. Where a town grants a street railway franchise, the contract limiting the rate of fare between any two points, an individual who has been ejected from a car for refusing to pay more than that rate may avail himself of the contract, in trespass for assault and battery.

3. Under Pub. Laws 1891, chap. 975 (Act May 29, 1891), authorizing towns to make contracts granting franchises to corporations operating street railways, section 4 of which provides that the charge for service shall not exceed the price charged by the corporation at the time of granting the franchise, a contract which limits the rate of fare to less than that then charged by the corporation is not beyond the town's authority.

4. Where a party boards a street car, tenders a certain fare, and, on refusing to pay more, is ejected, an action by him is not a moot case, which the court will refuse to entertain, though the party's sole motive was to make a test case.—(Adams vs. Union R. Co., 42 Atl. Rep., 515.)

UTAH.—Self-Executing Statutes—Franchise Is Contract—Waiver of Breach—Status of Privileges Granted—Franchise—Breach of Condition—Waiver—Strangers to Contract Without Right—Forfeiture of Franchise—Procedure—Articles of Incorporation—When May Be Amended.

1. The various legislative acts under which the defendant street railroad company was incorporated, containing provisions that, unless certain acts were performed within a certain time, the "act of incorporation shall be void," and being later amended by adding the words "as to all parts of its chartered lines not then constructed," it is contended that such provisions are self-executing, and that, having failed to comply with the terms of the acts, defendant's rights have been forfeited. Held, that such contention is inconsistent with plaintiffs' allegation that defendant is a corporation, and of no avail.

2. A franchise is a contract between the State, or other body granting the franchise, and the party accepting and acting upon it. It is governed by the general rules applicable to contracts, and either party may waive any breach of the conditions of a franchise; and anything which would constitute a waiver of a breach of a contract constitutes a waiver of a breach of the conditions of a franchise.

3. The waiver of a breach, which, if insisted upon, would forfeit the franchise, or some special right under it, leaves the party in default free to enjoy the privileges granted until the State moves in the matter, and a forfeiture has been judicially declared.

4. The defendant company having been in operation for a period of about twenty-seven years, and no proceedings having been instituted by either State or city to forfeit any of the rights granted by the franchises to the defendant company, and additional franchises having been repeatedly granted, all defaults on the part of the defendant company up to the date of the last franchise (March 18, 1894) have been waived; and the plaintiffs, being strangers to the contract, have no rights in the premises.

5. The act authorizing the city to grant a franchise to defendant company imposed no restriction, except as to the time for which the franchise should be granted. No rights can be forfeited, therefore, except for the causes and in the mode prescribed in the franchise, and Rev. St., sec. 438, is not applicable.

6. There being no statutory time limit within which articles of incorporation may be amended, an amendment may be made more than ten years after filing the original articles; and, in the case at bar, the amendment having been made in 1889, seventeen years after filing the original articles, Rev. St., sec. 438, could have no application, except to the amended articles, and, as to such, there was no default when this action was commenced.—(Dern et al. vs. Salt Lake City R. Co., et al., 56 Pac. Rep.)

VIRGINIA.—Contract to Build Railroad—Liability to Sub-Contractor—Extras—A railroad company which has let a contract for the construction and equipment of its road is not liable to a sub-contractor for extra work done by him in constructing it under his contract with the principal contractor.—(Richmond Ry. & Elec. Co. vs. Harris, 32 S. E. Rep., 458.)

UNITED STATES COURTS.

WASHINGTON. — Jurisdiction — Citizenship — Circuit Court of Appeals—Decision—Conclusiveness—Supreme Court—Right of Appeal—Where jurisdiction of the Circuit Court originally depended on diversity of citizenship, Act Aug. 13, 1888, making the decree of the Circuit Court of Appeals final in such cases, applies, and prevents an appeal to the Supreme Court, though another ground of jurisdiction, under which such appeal might be taken, is developed in the course of the proceedings.—(Third Street & Suburban Ry. Co. vs. Lewis, 19 Supr. Ct. Rep., 451.)

LIABILITY FOR NEGLIGENCE.

DELAWARE.—Collision at Crossing—Negligence—Evidence—Opinions.

1. It is competent for a motorman of an electric car injured by collision with a wagon, claimed to have been negligently driven in front of the car, to show that the car which was run on schedule time, was on time when the accident occurred.

2. Question asked one suing for personal injuries whether he feels that he will ever again be able to do a good day's work, or recover from his injuries, is improper.

3. A motorman of an electric car, suing for injury from collision with a wagon who has given evidence that he was careful in handling the car at the time of the accident, and that the apparatus was then in good condition, cannot, before any attempt of defendant to show that he was an incompetent or careless man, give evidence that he was habitually careful to see that his car was in order.

4. A witness who has stated that when he saw the driver of a wagon whip up his horses, and the proximity of the car, there was bound to be a collision, cannot state why he says that.

5. A motorman suing for personal injuries received from collision of his car with a wagon cannot show the result of a hearing had by the motorman before a magistrate on a charge of reckless driving.

6. Plaintiff may ask his witness, who has testified that he saw a

car, and that, in his judgment, it was going about 5 miles an hour, whether he was safe in saying that he thought it did not exceed 5 miles an hour.

7. The owner of a team sued for injury to a motorman whose car collided with the team cannot state whether he has observed how long it will take a team to go from the side of the street to the car line, with the horses at a walk, any observations being immaterial, as the speed at which horses walk varies.

8. Where at foot of a hill, down which an electric car had come, there was a collision between it and a wagon, one not called as an expert cannot testify to a test made of a car going down a hill as steep as that in question, and of the space within which the experiment showed a car could be stopped.

9. The right of a person in charge of a street car and of a person driving a team to the use of the street at a crossing must be exercised with due regard to the right of the other, and in a reasonable and careful manner, so as not unreasonably to abridge or interfere with the right of the other.—(Price vs. Charles Warner Co., 42 Atl. Rep., 699.)

INDIANA.—Negligence—Driving Across Tracks—A plaintiff, driving at night in the direction of an approaching street car, which he can plainly see, is negligent in undertaking to cross the track when the car is so close that it strikes his horse before it is off the track.—(Citizens' St. Ry. Co. vs. Helvil, 53 N. E. Rep., 191.)

INDIANA.—Injuries to Passenger—Special Verdict—A complaint alleged that plaintiff notified the conductor to stop the car, and it could easily have been done; and, as the car approached the crossing, its speed was slackened; that plaintiff, being a passenger, was standing on the rear platform, and, as the car slowed down, the conductor, with his hands, "passed" plaintiff in front of him, to allow plaintiff to step off, which he did, taking hold of the railing and stepping down on the step, to be ready to step off when the car stopped; and, while he was so stepping down and off, the motorman suddenly turned on the electricity, so that plaintiff was thrown from the car. There was a general verdict for plaintiff. The special answers found that the car was running from 4 to 5 miles an hour, and there was no change in the amount of electricity used; that there was no evidence that the motorman turned the lever turning on and off the current; there was no finding that the speed was or was not increased; that plaintiff was getting ready to get off as soon as the car stopped; that he was not stepping from the platform to the step when he fell; and that he was trying to get off a moving car to avoid being carried past his destination. Held, that the special answers, being inconsistent with each other, could not control the general verdict.—(Citizens' St. R. Co. vs. Hoop, 53 N. E. Rep., 244.)

LOUISIANA.—Injury at Crossing—Contributory Negligence.

1. The authorities are numerous and uniform to the effect that a person whose business or pleasure occasions him to use the streets of a city which are traversed by electric cars, and particularly at street crossings, is guilty of negligence if he fails to employ proper precautions for his safety.

2. He is bound to look and listed for the approach of cars, and to exercise ordinary care and caution to avoid possible danger of a collision; and, should he see an approaching car in close proximity, it would be his plain duty to halt until same could pass by, rather than run the risk of an accident by attempting to cross the track in front of it.

3. Failing to take such necessary precautions for his safety, the injured party is guilty of that negligence which deprives him of the right to reimbursement for injury received.—(Dieck vs. New Orleans City & Lake R. Co., 25 So. Rep., 71.)

LOUISIANA.—Injury to Person on Track—Evidence.

1. One who heedlessly attempts to cross ahead of a car properly manned, if injured, has no one to blame but himself.

2. The motorman was not at fault, and none of the negligence charged by plaintiff was shown.

3. He exercised reasonable care to avoid the injury. He paid proper attention, saw the danger, and gave notice or warning, and did all he could to stop his car.

4. There was nothing out of repair about the car or the track, nor anything lacking to increase the danger in which plaintiff, the testimony shows, placed himself.—(Webster vs. New Orleans City & Lake R. Co., 25 So. Rep., 77.)

LOUISIANA.—Injury to Person on Track—Contributory Negligence.

1. A boy, eleven years of age, standing at night on the off side of the down-town track of defendant company's street railway, waiting for a car on the up-town track (which was furthest from him) to pass, and, that car having passed, without looking up the track nearest him, to see whether or not it was safe to cross, steps on the track, 12 or 15 ft. in front of an approaching down-town car, trips and falls, is run over, and his foot crushed. Held, a case of want of care on his part, barring recovery of damages; it being shown that, notwithstanding effort on part of motoneer to arrest car, it could not be done in that distance.

2. The motoneer had a right to suppose the boy was waiting for his car to pass, and to expect he would remain where he was out of danger until it had passed.—(O'Rourke et ux. vs. New Orleans City & L. R. Co., 25 So. Rep., 323.)

MASSACHUSETTS.—Personal Injury—Frightening Horse—Negligence—A horse drawing a buggy in which plaintiff was seated was driven in a public street near defendant's electric car, which made a loud noise and threw sparks from its wheels. When the motorman rang the gong, the horse took fright, and plaintiff was injured. It did not appear that the noise and sparks were due to any defect in construction, or negligence in operating the car, and the horse did not appear to be frightened until the gong sounded. Held, no evidence of defendant's negligence.—(Henderson vs. Greenfield & T. F. St. Ry. Co., 52 N. E. Rep., 1080.)

MASSACHUSETTS.—Place of Accident—Rebuttal—Where plaintiff's evidence is that she was run over at a particular place, defendant's evidence that the accident happened at a different place does not make a fresh case, which plaintiff is entitled to meet; so that admission or exclusion of evidence on rebuttal corroborative of plaintiff's statement is discretionary.—(Lansky vs. West End St. Ry. Co., 53 N. E. Rep., 129.)

MASSACHUSETTS.—Injury to Employee—Negligence of Superintendent—Defective Appliances—Evidence—Assumption of Risk—Contributory Negligence.

1. A car shifter, whose only duties were to get cars ready for conductors and motormen, starting the turntable at a car house, was not a foreman, nor engaged in an act of superintendency, in so turning the table, within St. 1887, chap. 270, authorizing recovery by one injured by negligence of a superintendent.

2. Where plaintiff was injured by alleged defective appliances, evidence of a change in such appliances after the accident is inadmissible.

3. Where a servant knew of the danger of the work in which he was engaged, he cannot recover having assumed the risk.

4. Where a conductor of a street car had an experience of three or four years with transfer car tables, he was guilty of contributory negligence, where he was injured by an obvious danger in the use of such table, though he had not observed it.—(Whelton vs. West End St. Ry. Co., 52 N. E. Rep., 1072.)

MASSACHUSETTS.—Negligence—Evidence—Witnesses—Instruction—Service on Corporation.

1. A request to rule, in an action against a street railway company for injury to a passenger, that on all the evidence defendant had proved there was no negligence on its part, and had thus overcome the effect of the evidence of the mere running off the track by the car, and to direct a verdict for defendant, is properly refused, there being evidence that the car had run off the track an hour before the accident, and that, immediately before it again ran off, causing plaintiff's injury, it was running at the rate of 15 miles an hour, down a grade, and around a curve.

2. In the absence of any other adequate explanation, negligence of a street car company may be inferred from the going off the track of a car, injuring a passenger, there being evidence that it had gone off the track an hour before, and that immediately before it again ran off, causing plaintiff's injury, it was running at the rate of 15 miles an hour, down a grade, and around a curve.

3. What inference shall be drawn from failure to call a witness equally within the reach of the parties is for the jury to say under all the circumstances.

4. Error cannot be predicated of an instruction, on a second trial, as to witnesses who testified at both trials, that the only purpose and effect of showing their testimony at the former trial is to affect the weight of their present testimony, the instruction evidently referring to witnesses as such, and defendant's exception thereto giving no intimation that it was understood to refer to plaintiff as a party whose previous testimony might be evidence against him in the nature of an admission.

5. Motion to dismiss for want of proper service on defendant corporation is properly denied, service on it by serving its assistant treasurer being returned, and no plea in abatement being filed, and it being impossible to know, as matter of law, that he was not an officer having charge of defendant's business, within Pub. St., chap. 161, sec. 36, authoring service on such an officer.—(Harriman vs. Reading & L. St. Ry. Co., 53 N. E. Rep., 156.)

MASSACHUSETTS.—Master and Servant—Negligence—Jury—The rear truck of a street car was derailed at a switch, and swung around so that there was just room for a car to pass on the other track. The motorman was trying to right the car with a piece of iron under the derailed wheels, and his superior ordered him to remove the iron, and use a crowbar. As he stooped to pull out the iron, the superior ordered a car on the other track to "come ahead," and, as the motorman raised himself, he was caught

between the two cars. He heard the order given, but did not know to what car it referred, and the motorman on the other car did not know he was there. Held, that there was sufficient evidence of the superior's negligence on which to go to the jury.—(O'Brien vs. West End St. Ry. Co., 53 N. E. Rep., 149.)

MICHIGAN.—Damages for Personal Injuries—Pleading and Proof—Evidence—Instructions.

1. In an action for personal injuries, the fact that plaintiff's intended marriage had to be postponed on account of the injuries cannot be proved under a general allegation of mental suffering, since it was not a necessary consequence of the injury.

2. It is a violation of this rule to admit evidence of such fact, though the court charges that it "is not, independently, an element of damage, but an element" to be considered as bearing on plaintiff's mental suffering.

3. Manifestations and declarations of present pain may be proved, in an action for personal injuries, to show plaintiff's condition, though they were made long after the accident.

4. One who receives bodily injuries through the negligence of another may, under a general allegation of mental suffering, recover for the shame and mortification of being obliged to use a crutch and a cane.

5. Under a declaration alleging injury to the hip, hip joint, pelvis, and thigh, a resulting trouble to the sciatic nerve may be shown.—(Beath vs. Rapid Ry. Co., 78 N. W. Rep., 537.)

NEW YORK.—1. Evidence—Ejection from Cars—Res Gestæ. In an action for damages for ejection from a street car because plaintiff's transfer check had expired, evidence of statements by a third person to defendant's conductor, that he had seen plaintiff get off one car an onto the next one, is inadmissible as part of the res gestæ.

2. Same—Hearsay.

It is also inadmissible because it is hearsay.

3. Trial—Objections to Evidence—Waiver.

A party does not waive objections to the admission of evidence by endeavoring to rebut it.—(Woods vs. Buffalo Ry. Co., 54 N. Y. Suppl., 735.)

NEW JERSEY.—Death by Wrongful Act—Right of Action—Pleading—Amendment.

1. A father, as such, cannot maintain an action to recover for the loss of services upon the death of his son, caused by the negligence of another. The action to recover pecuniary damages resulting to him by the death of his son is only maintainable, under the death act (1 Gen. St. p. 1188), by the personal representative of the deceased son.

2. After an action has been commenced by the father as such, and declaration has been filed, to which a demurrer has been presented, an amendment to the summons and declaration, substituting the personal representative of the deceased party as plaintiff in the action, under the death act, will not be allowed, because it would be the institution of a new action between different parties, and raising new questions, and would be vexatious, especially if it appear that the statutory period in which the new action could have been brought has expired. By such an amendment the defendant would be deprived of a plea which it could have if the action was commenced in the name of the personal representative of the deceased.—(Fitzhenry vs. Consolidated Traction Co., 42 Atl. Rep., 416.)

NEW YORK.—Injuries to Persons in Street—Negligence.

1. A street car on a populous street ran over a four-year-old boy, who started to cross the street when the car was 100 or 125 ft. away. The car was going down a steep grade at about twenty miles an hour. The usual rate of speed of a car was eight or ten miles an hour, and, traveling at such rate, it could be stopped within 20 ft. As the boy began to cross the street, a person in an adjoining house and passengers in the car screamed, and the motorman looked at the house, then at the passengers, and then began to stop the car, which was 40 ft. away from the boy, but its speed was such that he was unable to bring it to a standstill until the boy had been run over. Held, that the question of the motorman's negligence was for the jury.

2. Same.—It was the duty of a motorman to keep the car under such control as to be able to bring it to a standstill in time to avoid injury to persons on the street.—(Fullerton vs. Metropolitan Street Railway Co., 55 N. Y. Suppl., 1068.)

NEW YORK.—Directed Verdict—Judgment on Appeal—New Trial.

1. Code Civ. Proc., sec. 1187, authorizes the court to submit issues to the jury pending a motion to direct a verdict, and thereafter direct such verdict as either party is entitled to, and on appeal requires judgment to be entered in favor of the proper party. Held, that where there were erroneous rulings on the trial, duly excepted to, the Appellate Division would not render judgment on appeal, but would order a new trial, as authorized by section 1317.

2. Same.—Where the court properly submitted the question of negligence and contributory negligence to the jury, and directed it to assess plaintiff's damages, and such issues were found in plaintiff's favor, it was error to direct a verdict for defendant.

3. Witnesses—Impeachment—Evidence.—A policeman made a memorandum of an accident he had seen, which he gave to the desk sergeant, who entered its substance in a blotter. In an action based on the accident, the policeman testified that, after being subpœnaed, he asked the sergeant to read the entry to him, and that it was correct. Held, error to refuse to allow witness to read the entry, and state whether it had been correctly read to him, where it differed materially from his testimony; and this, though the original memorandum was not produced.

4. Same.—In an action based on an accident, a police desk sergeant testified that just before the trial the policeman who had reported it asked him to read his report to him. Held, error to refuse to allow witness to state whether he read the report to the officer correctly; the latter's testimony concerning the accident differing materially from his report, and he having also testified that the sergeant read the report correctly.—(Sullivan vs. Metropolitan St. Ry. Co., 56 N. Y. Suppl., 88.)

NEW YORK.—Infants—Loss of Wages—Right to Damages.

1. An infant cannot recover damages for the loss of wages unless he has been emancipated.

2.—Same—Allegation of Emancipation.—An allegation in a petition by an infant for the appointment of a guardian ad litem, that deponent "is unable to perform any work, and has been seriously injured and damaged," is not an allegation of emancipation, evidence of which entitles the infant to damages for loss of wages.

3.—Evidence—Pleadings.—The allegations in a pleading are not admissible as evidence in favor of the pleader.

4.—Judgments—Conclusiveness—Parties in Different Capacities.—A judgment in favor of an infant for damages for loss of wages in an action by his father as guardian ad litem is not conclusive against the individual right of the father to recover for the loss of the same services.

5.—Appeal—Remittitur.—Where a judgment in favor of an infant contains an improper element of damages, consisting of loss of wages, and the amount of such item clearly appears, he will be allowed to enter a remittitur.—(Lieberman vs. Third Ave. R. Co., 55 N. Y. Suppl., 677.)

NEW YORK.—Collision—Negligence—Presumptions.

1. A passenger in a street car, suing for injuries caused by a collision between it and the car of another railroad company, must prove that such other company was negligent, as its negligence will not be presumed merely from the happening of the collision.

2. Same—Appeal—Instructions—Error Cured.—Error in charging that the happening of a collision between defendant's street car and the car of another, in which plaintiff was a passenger, makes it incumbent on defendant to prove that it was not negligent, is not cured by the granting of a request to charge that the mere fact that defendant's car struck the blow does not prove negligence on its part.—(Falke vs. Second Ave. R. Co. et al., 55 N. Y. Suppl., 984.)

PENNSYLVANIA.—Boarding Car — Negligence.—While a street car which had reached the end of its run was being prepared for the return trip, a person mounted the running board before the barrier preventing him from entering on that side had been removed, and was struck by a car on the other track. Held, that the company was not negligent in failing to provide against such an act.—(Malpass vs. Hestonville M. & F. Pass. Ry. Co. et al., 42 Atl. Rep., 291.)

PENNSYLVANIA.—Collisions — Contributory Negligence.—One who drives at a trot upon an electric railway crossing, without slowing up and looking for a car after obstructions preventing a view from the house line are passed, cannot recover for injuries caused by a car, though it was negligently operated.—(Darwood vs. Union Traction Co., 42 Atl. Rep., 290.)

PENNSYLVANIA.—Negligence—Personal Injury—Instructions.—Where the accident on which an action for a severe injury is founded was apparently trivial, and did not indicate that serious results would follow, and no notice thereof was given to defendant until the action was brought, a year and a half later, it is a case calling for full instructions as to the duty of plaintiff to make out affirmatively every element essential to recovery.—(Cooley vs. Philadelphia Traction Co. et al., 42 Atl. Rep., 288.)

PENNSYLVANIA.—Accident to Conductor—Master's Duty to Instruct—A street car company is not bound to instruct a conductor of nine years' experience, when taking out for the first time an open summer car, with a running board on the side, whereby it was extended nearer cars on the other track, of the danger of being struck by such cars while on such board.—(Fletcher vs. Philadelphia Traction Co., 42 Atl. Rep., 527.)

PENNSYLVANIA.—Accident to Child—Question for the Jury—The question of negligence is for the jury where a child of six years old, who had been playing on a lot abutting the street, known to the motorman to be a usual playground for children, immediately before the accident ran from a point 40 ft. from the curb line to and upon the street, and came in contact with the car as soon as he reached the track, the distance from the curb to the track being 5 ft., and there being evidence that the car was running at an unusual and excessive rate of speed, by gravity down grade, without the gong being sounded, or other warning being given; that, if the electric current had been used, the car could have been stopped inside of 10 ft.; and that the boy was struck by the front of the car.—(Walbridge vs. Schuylkill Elec. Ry. Co., 42 Atl. Rep., 689.)

PENNSYLVANIA.—Collision—Car and Runaway Team—Negligence—There is no evidence of negligence of the motorman of the street car, with which plaintiff's runaway horse, which he was driving, collided, where it only appears that plaintiff, when 60 ft. or 80 ft. from the crossing, shouted to the motorman to stop his car, and that the latter, who had started to cross, without coming to a full stop at the crossing, proceeded to cross the street, either not hearing plaintiff, or electing to do otherwise than he said.—(Phillips vs. Peoples' Pass. Ry. Co., 42 Atl. Rep., 686.)

MISSOURI.—Ordinance—Creation of Civil Liability—Pleading—Verdict.

1. The violation of a municipal ordinance, regulating the running of street cars, resulting in an injury to a passenger, cannot be made the basis of a civil liability by a mere allegation that such ordinance was in force and binding on defendant, since it must be alleged and proven that defendant agreed to be bound by the ordinance.

2. Where a complainant combines a good cause of action with an invalid one, and the court instructs that he can recover on either, the verdict must be set aside, since it cannot be distinguished whether the verdict rests on that for which there was no legal foundation, or otherwise.—(Byington vs. St. Louis R. Co., 49 So. W. Rep., 876.)

MISSOURI.—Cable Cars—Negligence of Gripman—Jerks—Imputed Negligence—New Trials.

1. A complaint setting forth as the negligence the act of the gripman of a street car in negligently operating the grip iron so as to cause the car to jerk with such force that it broke plaintiff's hold, and threw him on the street with great force, limits plaintiff to proof of the specific negligence averred.

2. Evidence that plaintiff was thrown from a cable car by a jerk of the car caused by some action of the gripman, without showing what the gripman did, or how he caused the jerk, or that he caused it at all, is not prima facie sufficient to submit to the jury the question of the gripman's negligence.

3. The fact that a cable car gave a sudden jerk, throwing plaintiff from the running board, is, per se, insufficient to make the company liable.

4. It appearing that jerks in the running of cable cars are unavoidable, because of the slack in the rope, negligence will not be imputed to the company merely because of such a jerk.

5. A verdict rendered for the right party, though under erroneous instructions, should not be disturbed by the trial court.—(Bartley vs. Metropolitan St. Ry. Co., 49 S. W. Rep., 840.)

NEW JERSEY.—Damages for Personal Injuries—Where the plaintiff claims that a nervous condition has resulted from an accident for which the defendant is responsible, the defendant may show the existence of a fact, other than the accident, from which it may reasonably be inferred the nervous condition has sprung.—(Mullin et al. vs. Consolidated Traction Co., 42 Atl. Rep., 764.)

NEW JERSEY.—Electricity—Live Wire—Injury—Question for Jury—Evidence—Physicians—The plaintiff picked up a wire that was lying in a public highway, and was injured by an electric current. He brought suit against the telephone company, whose wire it was, and against the trolley company, whose current, it was contended, did the harm. Held:

1. That the question whether the lineman of the telephone company had been reasonably diligent in discovering the fallen wire, and in preventing probable injury, was properly left to the jury. Also, that:

2. Whether the failure of the trolley company to use guard wires was negligence by which the plaintiff was injured was for the jury.

3. Testimony that a witness had certain uses of his hand, after an accident somewhat similar to the plaintiff's was properly excluded.

4. If the plaintiff used reasonable care in the selection of a reputable physician to cure his injury, he cannot be kept out of damages because with a better physician he would have had better results.—(New York & N. J. Teleph. Co. et al. vs. Bennett, 42 Atl. Rep., 759.)

NEW JERSEY.—Injury to Passenger—Presumption of Negligence—In a suit brought against a street railroad company by a passenger for injuries caused by the derailment of the car, proof of the happening of the accident is sufficient to charge the company with negligence, and to place upon it the burden of showing that the injuries were not received through any fault on its part.—(Bergen County Traction Co. vs. Demarest et al., 42 Atl. Rep., 729.)

NEW YORK.—Injuries to Passengers—Exemplary Damages—Evidence—Before a passenger in a street car could take her seat she was thrown on the floor and injured by the sudden starting of the car, or the speed at which it was run around a curve. The officers of the company did not direct the starting of the car in such manner, nor did the conductor and motorman intend to injure the passenger. Held, insufficient to justify an award of exemplary damages.—(Wigton vs. Metropolitan St. Ry. Co., 56 N. Y. Suppl., 647.)

NEW YORK.—Instruction—A requested instruction, "If you believe that the occurrence did not happen as plaintiff described it, then your verdict must be for the defendant," is too broad, requiring a verdict for defendant if some essential detail was incorrectly stated by plaintiff.—(Bendit vs. Third Ave. R. Co., 56 N. Y. Suppl., 789.)

NEW YORK.—Bicyclists — Collisions — Contributory Negligence—An expert bicyclist, familiar with the streets and the dangerous situation into which he was riding, was following a downtown car, and when it stopped he turned out and passed it, crossing to the opposite track, and was struck by an uptown car, which, when he turned out, was only 25 ft. away. Held, that freedom from contributory negligence was not shown.—(Cardonner vs. Metropolitan St. Ry. Co., 56 N. Y. Suppl., 500.)

NEW YORK.—Injury to Person on Track—Where a woman, in full possession of her faculties, with an unobstructed view of a street railroad track for several blocks, glances up and down the street from the sidewalk, and then walks slowly upon the track, with an approaching car fully in view, and is run over, she is guilty of contributory negligence.—(Hickman vs. Nassau Elec. R. Co., 56 N. Y. Suppl., 751.)

PENNSYLVANIA.—Injury to Bicyclist—Negligence—A boy on a bicycle turned a corner, and in passing around a wagon, which stood between the curb and the defendant's tracks, struck a car which was approaching on a track so close to the wagon that there was no room for the bicycle to pass between. The motorman had his head turned, looking for people approaching from the opposite direction, but the bicyclist could not have been seen until he rode past the end of the wagon, when the car was so close that it would have been impossible to stop it in time. Held, that the motorman was not negligent.—(Gould vs. Union Traction Co., 42 Atl. Rep., 478.)

UNITED STATES COURTS—(WISCONSIN).

Collision with Bicycle—Negligence—Plaintiff, who was deaf, was riding a bicycle, and crossed one of the two parallel tracks of an electric street railroad, not more than 50 ft. in front of an approaching car, and, turning, continued in the same direction the car was moving, riding in the space between the two lines, which was 4 ft. wide. Not exceeding twenty seconds later his arm was struck by the passing car, and he was thrown from his bicycle and injured. The motorman on the car turned off the current when he saw plaintiff start across the track, but turned it on again when plaintiff had crossed, though he continued to sound his gong until the accident occurred. He had no knowledge of plaintiff's deafness. Held, that, giving plaintiff the benefit of the broadest construction of the qualification of the rule as to contributory negligence, which would permit him to recover notwithstanding his own gross negligence, if defendant might, by the exercise of reasonable care and prudence, have avoided the consequences of such negligence, there was nothing in the evidence to charge the defendant with liability, as the motorman was justified in supposing that, after having crossed in safety, plaintiff would keep at a safe distance from the track until the car passed.—(Nein vs. La Crosse City Ry. Co., 92 Fed. Rep., 85.)

NEWS OF THE MONTH

The original design for the tickets to be used by the Indianapolis Street Railway Company when the new four-cent fare arrangements go into effect, was not acceptable to the city authorities because it bore the words "Not good if detached." The company thereupon yielded the point and all tickets will be so worded as to be good when detached and tendered by any person to a conductor, and will entitle the possessor to transportation and a transfer to any line and to all other privileges the same as if a cash fare had been paid.

The April issue of the "Technology Review," the new magazine devoted to the interests of the Massachusetts Institute of Technology, contains articles on "Applied Science and the University," by James P. Munroe; "Institute Men in the Spanish War," several papers upon the institute facilities and athletic and other interests, and 1 any notes of much interest to graduates and undergraduates.

After a long discussion with the city officials, the Indianapolis Street Railway Company has finally been granted a new franchise, its old one having expired. The new franchise is for thirty-four years, and under it the company is to pay the city $1,160,000 in cash in instalments, and is to sell six tickets for a quarter, and twenty-five tickets for one dollar, all tickets to have transfer privileges. The company is also compelled to bear the cost of paving between the tracks and for 18 ins. on either side.

It is stated that about 318 cars, including regular bridge cars and trolley cars, pass over the Brooklyn Bridge every hour.

The New York, New Haven & Hartford Railroad Company has decided to extend immediately the third rail electric system on its Plymouth division from Nantasket Junction to Cohasset, a distance of about 3½ miles.

The power station of the Huntington Railroad, of Huntington, L. I., is one of the first street railway plants to be operated by gas engines. This road is 3 miles long, operating one car in winter and three cars in summer. As there is a steep grade on the line, the load is, of course, an extremely variable one. The power-house equipment consists of two Westinghouse, three-cylinder vertical gas engines, each of 50 nominal h.p., taking their gas supply from the adjacent works of the local gas company. Each engine is belted to a 27½-kw. Westinghouse four-pole, 550-volt generator. A storage battery of 265 cells is used to equalize the load. It is stated about 46 cu. ft. per car mile of gas is used. The car mileage is about 200 miles per day.

The International Traction Company, recently formed to purchase and consolidate the Buffalo and Niagara Falls street railway properties and others in Western New York, has organized, with W. Caryl Ely, of Niagara Falls, as president; Daniel S. Lamont, President Cleveland's former Secretary of War, as vice-president, and Bi rt Van Horn as general manager. The new company has assumed control, and is now operating, the Buffalo and Niagara Falls street railway properties, the Buffalo & Niagara Falls Electric Railway, the Buffalo & Lockport Electric Railway Company, and others.

The Board of County Commissioners at Indianapolis has reduced the proposed charges set out in their schedules by the several interurban electric railways leading out of that city and across the county to one and two-fifths cents per mile.

By an order recently promulgated by the War Department, provision is made for the extension of the legal effect of any present or future United States patents to Cuba, Porto Rico, the Philippine Islands, and any other territory subject to military government by the forces of the United States. The order also applies to trade marks. By observing certain formalities the necessary record can be effected.

The convention of the Amalgamated Association of Street Railway employees will be held in Louisville some time in May, 1899.

The Sandusky, Milan & Norwalk Electric Railway Company, of Sandusky, Ohio, has restored the wages of conductors and motormen to 15 cents per hour from 12½ cents, the rate at which the men worked during the winter.

A bill authorizing the sale of property left in street surface railroad cars, and the disposition of the proceeds for the benefit of any of the employees and societies existing among the employees of the corporation has recently passed the New York State Assembly.

The Mahoning Valley Street Railway Company, of Youngstown, Ohio, has made an increase in wages in all departments. Motormen and conductors will now receive 14, 15, 16 and 17 cents per hour, according to class.

The Third Avenue Railroad Company has built a temporary track through 125th Street, and will operate this line with horses until the new electric conduit construction is completed. It has been found necessary to take out all the old cable construction on this line, including the yokes.

The Cincinnati Street Railway Company, of Cincinnati, Ohio, is planning to greatly enlarge its shops, so as to enable it to build all its own cars.

Several new cars, including a mail car, are being built in the shops of the Rochester Railway Company, of Rochester, N. Y.

It is stated that the experiment of giving vaudeville shows on special cars while en route will be tried in Brooklyn, N. Y. The car will be extra long, and at one end will have a small stage. At the other end will be a diminutive smoking apartment. The fare on this car will be 25 cents.

The Milwaukee Electric Railway & Light Company claims that it is losing thousands of dollars a year through the illegitimate use of transfers by the public, and a bill has been introduced in the Wisconsin Legislature providing that persons convicted of selling or giving away their transfers shall be fined from $5 to $10.

All of the city and suburban lines of Wheeling, W. Va., were tied up for several days recently owing to a strike of the conductors and motormen. The men demanded nine hours a day, at 20 cents an hour, and a recognition of the union. Much rioting and disorder attended the strike.

It is proposed to hold a World's Fair in the city of St. Louis in 1903, celebrating the centennial of the Louisiana purchase, and it is intended to make this exposition second to none in history. The project involves the organization of a stock company with a capital of $5,000,000, and with a par value of $10 per share. A popular subscription is invited, the first payment to be 5 per cent, and no subsequent calls for payment to be made exceeding *in toto* 20 per cent of the amount subscribed. All subscriptions are contingent on the securing of at least $5,000,000 in all, and except for the first payment of 5 per cent, no further calls on subscribers will be made until the aggregate subscriptions amount to $5,000,000. The city of St. Louis proposes to help the enterprise by increasing its bonded indebtedness $5,000,000, and the National Government will be asked for a loan of $5,000,000, and the State of Missouri for a loan of $2,500,000. It is believed that with the $17,500,000 thus secured an exposition will be obtained rivaling that of Chicago, where the total expenditure, before the opening of the gates, amounted to $18,600,000.

An interesting decision has recently been handed down by the Supreme Court against the Nassau Electric Railroad Company, of Brooklyn, affirming that street railway companies are liable for accidents caused by falling trolley wires, even though it has not been proven that the company was negligent.

Foreign Visitors in America

During the month of April several British engineers have visited the United States on tours of inspection of electric railway work. Among them was Prof. A. B. W. Kennedy, one of the most prominent of British electrical engineers, who is consulting engineer for the London County Council with special reference as to whether or not the underground electric conduit system is practicable for the conditions found in London. Prof. Kennedy in pursuance of this investigation visited New York, Hartford, Boston, Schenectady, Buffalo, Niagara Falls, Chicago, Pittsburgh, Washington, Baltimore and Philadelphia, on a flying trip extending over but two weeks, and at its conclusion expressed himself as very much interested in what he had seen. Accompanying Prof. Kennedy was E. W. Monkhouse, an electrical engineer of London, who desired to make a careful investigation of electric

railway practice in this country in behalf of other clients. On April 13, Dr. Edward Hopkinson, managing director of Mather & Platt, Ltd., and Bertram Hopkinson, nephew of the late Dr. John Hopkinson, arrived in New York, and are now making similar investigations in various cities of the United States with a view to acquiring a general understanding of the best American practice in electric railroading. They expect to return in May.

New Manufacturers of Electric Railway Apparatus in England

Dick, Kerr & Company, the widely known railway contractors and manufacturers of England, are at the head of a syndicate which is about to form a company with a capital of £200,000 to carry on the manufacture of dynamos, motors and controllers (for electric railway purposes only) for the British home and foreign trade. The members of this syndicate are Dick, Kerr & Company, Ltd.; John Kerr, George Flett, Claude T. Cayley, Benjamin Sykes, T. S. Turnbull, Richard Prestwich, John Prestwich, George Readman, W. J. Kirk and Sidney H. Short. All except Mr. Short's are well known names in British business and financial circles, and Mr. Short has an international reputation as an electrical engineer and designer of electric railway apparatus through his connection with the Brush Electric Company, the Short Electric Railway Company, and the Walker Company, and through the many papers which he has contributed to scientific bodies on electrical engineering matters. The name of the new company is not yet determined upon, nor its officers selected, but Mr. Short will be in charge, as technical director, of the design of the machinery to be built by the new company.

It will be remembered that not long ago the Electric Tramway & Carriage Company, of Preston, Eng., was organized by another syndicate headed by Dick, Kerr & Company, and a large factory was constructed in Preston. Opposite this factory, a tract of 11 acres of ground has been secured as a site for the new railway motor and generator works, and the foundations are now under way for buildings which will cover about 4½ acres of this plot. The main machine shop will be 900 ft. x 120 ft., and in connection with this will be a foundry 400 ft. x 80 ft., together with pattern shops, offices, store rooms and other buildings usual with a plant of this kind. Electric power will be used throughout the works for running all machinery, and the capacity of the shops is expected to be 1200 equipments per annum of motors, and 30,000 kw. of generators. The buildings will have a steel framework with brick facings, and it is expected that the works will be in full operation by Jan. 1, 1900.

Mr. Short has engaged S. B. Fortenbaugh to go with him across the water as technical assistant, and it is the purpose of the syndicate to engage in America the principal superintendents needed for the new operations. On April 13, Messrs. Flett, Cayley, Turnbull and Short arrived in New York, via S. S. Teutonic, in order to make these engagements and to purchase the machinery and possibly the structural material for the new works. Contracts for at least $120,000 worth of machine tools will be placed in America, and orders have already been given to E. W. Bliss & Company for the presses, and to the Kemp-Smith Company for milling machines, and the remaining orders will be placed before May 6, when the entire party sails from New York for Liverpool. Orders for the engines were placed in England with the Musgraves, of Bolton.

The well known energy and indefatigable determination of Dick, Kerr & Company in pursuit of electric railway business in Europe have won them hosts of friends, and there is no question about their ability to fill their new electric railway works to overflowing with orders. One of the interesting features of the entire transaction, and one characteristic of British quickness to take advantage of opportunities for investment is found in the fact that the entire capital for the construction of the works, £200,000, was subscribed in about thirty minutes, and no subscription of less than £10,000 was accepted, while the desire to obtain larger amounts than could be alotted was urgent.

One of the unpleasant features about this new enterprise is that Mr. Short's friends in America will lose him for several years at least, as in pursuance of his contracts with the new company he will have to take up his residence in England. He returns with Mrs. Short to England on May 6, as stated above, and will shortly be followed by the remainder of his family. He has leased for several years a beautiful house and estate in Weybridge, one of the most charming of London's suburbs, and has been fortunate in securing one equipped with all the modern improvements, including a system of heating by hot water, a rare thing to find in England.

Municipal Ownership in Detroit

In March last, H. S. Pingree, Governor of Michigan, affixed his signature to the so-called "McLeod" bill, thus creating it a law. This bill gives the city of Detroit the power to acquire and operate all the street railway lines in that city and gives the conditions under which they are to be so acquired. As is quite generally known, municipal ownership is one of the pet theories of Governor Pingree, and he has been endeavoring for a number of years to put his opinions into actual practice. To this end about a year ago he opened negotiations with T. L. Johnson and R. T. Wilson, the holders of a majority of the stock of the Detroit street railway properties looking to the transference of the roads to the city at a price to be decided by a commission. The new bill is the result of these negotiations.

There are twelve sections in the bill and its provisions are briefly as follows: The Common Council of the city of Detroit is authorized to appoint three persons who shall constitute a board of commissioners to be known as the Detroit Street Railway Commission. One of these commissioners shall be appointed for a term of two years, one for a term of four years and one for a term of six years. At the expiration of each respective term, the Mayor shall appoint the succeeding commissioner for the term of six years. The bill expressly provides that no alderman shall be appointed on the commission. Before entering upon the duties of their office, the commissioners are severally required to execute a bond to the city of Detroit in the sum of $250,000 to secure the faithful performance of their duties. This commission, with the consent of the Common Council, is empowered to construct, operate and maintain, lines of street railway, to carry passengers and freight and to use the earnings of the road to that end. The commissioners are also empowered, if in their opinion it is deemed necessary, to issue bonds in the name of the city for such amount as may seem proper, the sum to bear interest not exceeding 4½ per cent per annum, and to be payable thirty years from date in gold. The bonds will not, however, be a charge against the city or the property of its taxpayers, but the commission will pledge for the payment of the bonds all assets and property connected with or relating to the line of the street railway constructed by said commission, and as additional security the commission is authorized to grant to a trustee a franchise to maintain and operate said line of railway for a term not to exceed fifty years and on such conditions as said commission shall deem proper. The rate of fare over a single line shall not exceed five cents for a single fare, and six tickets must be sold for twenty-five cents. In addition to this, the workingmen's tickets (at eight for twenty-five cents), already provided for by a street railway ordinance, will be maintained.

The franchise to be granted to the trustee shall be of no force except in the event of the default of the commission or said city in the payment of the bonds. In the event of such default the franchise is to be transferred to a corporation to be organized by the holders of the bonds and all rights, powers and benefits guaranteed by the franchise shall inure to the benefit of the holders of the bonds.

The bill expressly provides that the commissioners may purchase the present street railway lines in the city and may issue bonds to the necessary amount to pay for the same. These bonds are to bear interest at a rate not exceeding 4½ per cent per annum and to be made payable not more than thirty years from date. These bonds also will not be a direct charge upon the property of the taxpayers, but will be secured by the net earnings and tangible assets and property of the street railway lines purchased, and, in addition, by a franchise granted under similar conditions as mentioned above.

The three commissioners appointed are Governor Pingree, Carl E. Schmidt and E. G. Stevenson.

The price to be paid for the present street railway lines has not yet been fully settled. The companies are bonded for $11,000,000. It is estimated, however, that the system can be duplicated for about $5,000,000 at present prices. It is thought that the city will pay about $12,000,000 for the properties.

Late in April it was announced that a technical flaw had been discovered in the McLeod bill, and that the law would be declared null and void. It is claimed that the engrossed bill does not contain a clause which was in the original; namely, "Providing that nothing in the act shall affect the granting of franchises by the City Council." Governor Pingree thinks that this omission will not invalidate the law, but it is stated the street railway companies will make the alleged discrepancy a strong point in the proceedings they are about to bring in the courts to test the act.

Messrs. Issigonis and Piltacos, of Smyrna, have been granted a franchise for the construction of a railway in that city.

Some of the Larger Transportation Problems in Cities*

BY EDWARD E. HIGGINS

The managers of a large city railway system are constantly called upon to deal with problems of great difficulty and complexity. They have a double responsibility—a responsibility to the public and a responsibility to the investors of whose interests they are trustees. They are charged with the management of thousands of employees whose attitude toward the enterprise, whether of content or discontent, is of vital importance to its success. They must pass upon inventions and improvements in the science of municipal transportation, determining where costs and true economy join hands; they must adopt operating methods adequate to the development of the system and of the city which it serves; they must care for the comfort and pleasure of the public, and they must so unify all of these varied and sometimes conflicting duties as to develop an organization and management successful as a whole and not unduly weak in any part.

Grave misunderstandings often arise between street railway companies and the public. The people often believe the companies to be grasping, sordid, careless of their duties as public carriers, and desirous only of making the largest possible return to stockholders. The companies, on the other hand, daily harrassed by complaints about inconveniences suffered, small or large, often come to regard the public as unreasonable in its demands, forgetting that that public is not in a position to see all the difficulties and perplexities which beset the management at every turn, and which make it often impossible either to grant such demands or to explain why they cannot be granted. The street railway business as a whole is so complicated and so much a matter of detail that no one department of it can be well understood without some knowledge of the others, and fragmentary or partial explanations of the reasons for specific decisions, however sound in their relationship to the general plan of management, might not always or often appear so to non-technical critics.

I shall attempt in the following discussion to give such an explanation of the entire scheme of modern street railroading on its broad lines and of the principal problems which the manager has to solve as will lead to a clearer understanding by those who are not of "the faith" of what the public has a right to expect from the street railway companies, which are its servants and which are, as a rule, honestly trying to fulfill all the obligations which can reasonably be imposed upon them.

ESSENTIAL DIFFERENCES BETWEEN CITIES

In the first place, it cannot be too clearly made evident how different are the transportation conditions in each city from those of any or all other cities. Nothing can be more fallacious, or lead to greater injustice, than to say that because such and such concessions are granted by the companies to the people of a certain city, therefore, similar ones can and should be made in another city. The most common error of all, perhaps, is to assume that the conditions found in a small city obtain in a large one or vice versa. Population and population density have an enormous influence on street railway earnings, profits and possibilities of generosity. A second even more common error is to hold that as much ought to be expected from an old company which has passed through one or more experimental stages of street railroading and has had to throw away enormous investments for antiquated motive powers and to purchase their substitutes at high initial prices, as from a new company just entering the field, with all the accumulated experience of many years to draw upon, and with the benefit of the low prices for material and supplies of the present day. Behind these more obvious injustices come others less easy to understand without some technical exposition. How, for example, can a manager satisfactorily explain to the public the reason why the people of his city patronize their street railway system to the extent of only $3 per capita per annum, while in another city of the same population, the earnings are over $5 per capita? When the generosity of the richer system is cited as a precedent for the poorer to follow, it is a delicate matter to show that the latter's public is largely composed of the working classes to whom the daily five or ten-cent fare forms a material burden, or a difficult one to make clear that the plans on which the two cities are laid out are radically different, the one calling for greater patronage of street car lines than the other, without necessarily involving greater expense to the operating company. A knowledge of these differences in city plans and lines of development is so essential to the understanding of the theory of street railroading that a brief explanation of their effect upon earnings is desirable.

The world's great cities are, with scarcely an exception, built upon or around some form of water front—sea, lake or river. Upon some section of this water front is always found the "congested district" devoted to commercial and business purposes. The manufacturing districts of a city may or may not be on this water front, according to the location of the railroad termini and branches, the presence or absence of rivers tributory to the main water front, and other governing conditions. All, or nearly all cities are laid out and developed on one of four distinctive plans; first, the peninsula plan, such as that of New York city (Manhattan Borough) and San Francisco; second, the valley plan, with a river or rivers running through the center, such as Pittsburgh; third, the radiating plan, with territory on one side only of water front, such as Chicago, Boston, Brooklyn and many other cities, and fourth, the radiating plan with territory on both sides of the water front, of which examples are found in Metropolitan New York (including Eastern New Jersey), Paris, London and many other cities, large and small.

The peninsula and valley plans usually call for comparatively small street railway track mileage, and great traffic density is found on that mileage, together with large gross earnings per capita served, per mile of track and per car mile. For example, the complete transportation system of New York city proper (Boroughs of Manhattan and the Bronx) earns about $13 per capita gross, and that of San Francisco nearly $14. The radiating plans mean greater street railway mileage for the population served, and usually a much less density of traffic and less gross receipts per capita. The Chicago surface and elevated lines, for example, earn less than $10 per capita, and the surface lines of St. Louis hardly $8 per capita.

It can be easily seen how different, for example, is the transfer problem in a peninsula and valley city from that of a radiating city. In the former there may be a few through lines of heavy traffic with many cross-town feeder lines. Transfers in such a city might mean no additional expense to a company and little or no complications. In the radiating city, on the contrary, a transfer system might mean a ride of great length, while the plan of the system might be such that dishonesty in the use of transfers would be easily possible.

Again, a city plan very favorable to economical operation might make a four-cent fare possible in a given city, while in another city, even of the same population, such a fare would mean bankruptcy. A city system of large track mileage running many cars might have immense maintenance accounts to deduct from earnings, whereas a more fortunate one in another city would have a great traffic density on small mileage. All that a comparison of practice between the street railway systems of two cities can do, therefore, is to put the burden of proof upon the system which is apparently less generous with the public of showing why the more generous practice cannot be followed, and the company's argument should be received with attention and respect; for, after all, nothing is more certain than that the best reasonable service of the public will bring about the largest earning power to a street railway company, and none is more quick to recognize this fact than the average street railway manager.

THE FUNCTION OF ELEVATED AND UNDERGROUND RAILWAYS IN CITY TRANSPORTATION SYSTEMS

The question of adding to existing facilities or solving difficult congested district problems by the building of elevated or underground railways is facing the managers of several of the principal cities of the world, and it is a serious one indeed. The enormous cost of tunneling, and the hardly smaller combined investment required for building an elevated structure and paying damage claims to abutting property owners, leads, and will lead to a postponement of the issues as long as possible. The great tunnels of Paris are an immense burden upon French taxpayers, while private capital cannot hope to make a success of tunnel enterprises except in countries where rates of interest are extremely low, and even then the public must usually be called upon to help by special concessions or subsidies of one kind or another. The London Metropolitan underground system is a failure financially, partly because of its immense cost and partly because it was not properly laid out to obtain the greatest density of traffic. It is hoped that the new Central London Underground will be more successful, being comparatively short and built under one of the heaviest traffic routes of that great city. Private capital has so far shown very little enthusiasm for an underground railway in New York city, where, if anywhere in America, such a railroad should prove profitable.

The elevated railway system of Manhattan Island has been in the past exceedingly profitable, chiefly because it is built in a "peninsula city" *par excellence*, where an immense tide of travel sweeps south in the morning and north at night along few and narrow lines, but the fact that through all these years until the present time, the New York elevated lines have had as competitors only

* Lecture delivered before the Franklin Institute of Philadelphia, Pa., March 28, 1899.

comparatively slow-moving horse cars, has been almost equally potent in affecting profits, since short distance as well as long distance travelers have been obliged to use the elevated when time is an object. Elevated railroading in the two "radiating cities" of Brooklyn and Chicago has been distinctly unprofitable. In cities of this class it is difficult or impossible to find the density of traffic necessary for the payment of operating expenses and interest upon the heavy capital outlay required. This is particularly true where the surface cars are run at frequent intervals and at high speeds, for the latter will inevitably obtain the short distance, or more profitable class of traffic, leaving the long distance, or unprofitable class only to the elevated lines. Moreover, in cities of the radiating class, the population is usually spread out over so large an area as to make it impossible for any one line to obtain a large proportion of the traffic. The adoption of electricity on the elevated lines of Chicago has favorably affected gross and net earnings, and with the scaling down of capitalization which has recently been accomplished, there is a possibility that a reasonable return on the new capitalization can be made if new competitive conditions do not arise; a similar result is hoped for in Brooklyn. It is by no means improbable, however, that the only permanent solution to the problem of running surface, elevated and underground railways in the same city is to have them under one control and management, so that the surface lines can serve as feeders to the elevated or underground lines, an express service only to be given on the latter, and a fare charged for the combined service somewhat greater than the single five-cent fare.

In the congested districts of our principal cities, elevated or underground lines, either, or both, will find a true and valuable field. The business sections of Chicago and Boston furnish problems of the most serious and complicated character, which are only partially solved at present, and are likely to grow graver in geometrical ratio as the years go on, and as the territory tributary to the business centers increases in area and population. It is probable that the only permanent solution to congested district problems in cities lies in subway or tunnel lines and loops in these districts. These will take from the surface of the streets the enormous crowds of people which at morning and evening hours of the day pour into and out of the tall buildings which have become so necessary an evil in the modern city business districts. Boston's new subway is a decided, though not as yet a complete, success in relieving congestion and saving time throughout a large portion of the twenty-four hours. The new Boston elevated lines at present under construction will be of great assistance in this congested district, passing as they do from its limits on the north and west (the latter projected) to those on the south, and the managers of the great city railway property in Boston have done wisely in confining these elevated lines to the congested district and not carrying them to a greater distance away from the business center. In Chicago, the loop terminal of all the elevated lines, recently put into operation, has been a great convenience to the people, and has added largely to the traffic, but it is a question if it has not even so soon nearly reached its train capacity, particularly on days of its heaviest traffic, for on a recent holiday, no less than 65 per cent of the trackage on one of the loop lines of the structure was covered by trains, i. e., they were less than a train length apart on an average.

THE PROBLEM OF MOTIVE POWER

No decisions which street railway managers have been called upon to make during the past ten years have caused them such anxious solicitude, and have meant so much to the public and to stockholders, as those connected with motive power. Ten years ago horse traction was almost universal, with the cable in use or building on the heavy traffic routes of a few cities, and electricity just coming into sight. To-day electricity reigns triumphant, having displaced both horses and cable on nearly all the mileage of American cities. A synopsis of the reasons for this wonderful revolution in transportation methods which has completely changed the complexion of our cities and added new life and vigor to their daily routine, will be of present as well as retrospective interest, inasmuch as the primacy of electricity, and particularly of overhead wire electric traction, is still occasionally disputed.

All motive powers may be divided into two classes, those which make a car a more or less independent unit on the streets, and those which make it constantly dependent on some central source of power. To the first class belong the horse car, the storage battery electric car, the compressed air car, and various forms of gas, stored steam, petroleum and other motor cars. To the latter belong the cable system and the electric overhead wire and conduit systems.

Independence in the car unit is a highly desirable thing. With it comes minimum disturbance of the pavement or obstruction in the streets with minimum investment for installation; and with it comes also an avoidance of the danger that the central source of power may give out and stop the entire system or any large section of it for a considerable period. There is no question that a really successful independent unit system would be heartily welcomed by street railway managers, certainly as an auxiliary, and would find a large field immediately ready for occupancy.

But there are serious obstacles to success. It is probably impossible to devise a power generating and using system which will go within the narrow space limits available in a modern popular car, and which shall be capable of exerting as a maximum a power four or five times the average amount required for the propulsion of the car. Such a system can be placed in a dummy car and some room left for passengers as well, but when one or more trail cars are to be drawn, difficulties of traction come up immediately. At all times there is the impossibility of generating power in small amounts with anything like the economy with which it can be generated in large. If power be generated in quantities at some central station and stored in some one of several forms for transfer to and use on a car, that car is quite as surely dependent on the central station as it would be were the power transmitted by wires or cable, and is likely to give even more trouble through the exhaustion of the stored power and the consequent stoppage of the car on the line. Still another difficulty is found with so-called independent car operation (except where electric motors are used as in the storage battery system), and that is the impossibility of producing a rotary motion without the use of an initial reciprocating motion, with all the latter's well known disadvantages in the matter of wear of parts and reduction of tractive effort on grades, curves and in starting. Finally, such disagreeable concomitants as odor, noise, or danger of explosion must be excluded if the independent motor is to be an entire success.

Modern street railroading requires constantly increasing average speeds over city streets without increasing danger of accident. With the short runs between streets and the many stops necessary for taking on and letting off passengers, high average speeds can be obtained only by means of high rates of acceleration in starting, and correspondingly high braking effort in stopping. In other words, maximum speed must be reached as quickly as possible and kept up as long as possible before brakes are applied.

Now, the one propelling agency adapted for this peculiar class of work, so far developed in the entire transportation field, is the electric motor, with its constant rotary effort, or torque, and with its almost infinite capacity for automatically absorbing and transforming electric power into a rotary effort. A little 25-h.p. car motor can be overloaded 100 per cent or more if the occasion requires, and will take power until its wires actually melt in the process. There is no such reserve power in any form of reciprocating motion engine—no such constant torque and no such ease of control. Compressed air, stored steam, gas, petroleum and other motors all have their possibilities of development, mechanically and commercially, and when proven successful in practice on any considerable scale, there will be certain portions of the general transportation field open to them, but it is equally true that the electric motor has intrinsic advantages such that it will never be displaced in street railway service, while it is certain also that it will reach into larger transportation work now performed exclusively by steam locomotives.

Before proceeding further with electric motors, a word should be said about the cable system. It would appear at first sight that here also is found a system which would fulfill the requirement of maximum acceleration and braking possibilities, and consequent high schedule speeds. Maximum acceleration can certainly be obtained with the cable, as has frequently been demonstrated by a surly or incompetent gripman, to the great discomfort of passengers, but no cable line can compete with a parallel electric line in point of schedule speed for the reason that the maximum speed is limited to the speed of the cable, and the latter must be kept down to a point such that slippage through the grip is not continuous. In other words, there is little probability that cable cars, once behind their schedules, can catch up to them unless by rare good fortune in not being required to stop for passengers, while with the electric cars there is always the possibility of flying through the streets in the suburban or less congested streets so as to make up time lost elsewhere. As a matter of fact, the cable is disappearing from American street railroads, partly because it is not popular, as it is found that the people always prefer parallel electric lines because of the greater smoothness in running, and partly because of the greater economy in operation, demonstrated again and again in our leading cities where both motive powers have been used. The cable system is a complicated one with its immensely costly and cumbersome construction, which requires constant care and attention, and it is true, moreover, that a cable line cannot be sectionalized to the extent than an electric line can be done, to the end of minimizing the stoppage of traffic.

Granting, therefore, that the electric motor is the city trans-

portation agency of the present and the future, there remain to be considered the relative advantages of the overhead system, the conduit system and the storage battery system. In spite of numerous attempts to put the latter system upon a commercial basis, it has not yet been demonstrated to the satisfaction of street railway managers that it can be used with economy on a large scale, or that good acceleration and grade climbing work can be done where storage batteries alone are dependent upon for reserve and contingency requirements. The equipment of the Chicago and Englewood Street Railway with storage batteries is about the only ambitious experiment on a scale that is now being tried in this country, but abroad batteries are used quite largely and successfully in what is called the "mixed system," in which the overhead trolley system is used for suburban and outlying lines, and storage batteries for the business centers. The great difficulties in the way of storage battery work for transportation purposes lie in the great weight of the batteries to be transported, the deterioration of the plates, particularly when called upon for the widely varying power requirements of a street car, and the somewhat sluggish action of the cars in acceleration. It is by no means unreasonable to hope, however, that improvements will come in this line such that commercially successful storage battery cars may be made possible.

The central station method of operating street railway systems, particularly by electricity, has many intrinsic advantages. In the first place, power can be generated at such stations in large quantity and at extremely small expense. It is probable that in the largest street railway power station in the world now building in New York, the cost of power will be reduced to three-quarters of a cent per car mile, or less than 8 per cent of the total operating expenses of the system, this cost including all losses of generation, conversion, transmission and reconversion. The inherent advantages and possibilities of electric transmission for power purposes are such that it is difficult to conceive of a more perfect adaptation of means to the desired end. When, however, the matter of transmission is taken up in detail, three methods present themselves for selection, the overhead wire system, the open slot conduit system and the surface contact, or "Button system."

The overhead wire system is the one in almost universal use, and the wisdom of its adoption has been completely justified in a large majority of cases. It is inexpensive to install as compared with the other two systems; it is, when well put up, probably more economical than either, and troubles can be easily located and quickly remedied. Its chief disadvantage from the public point of view is the so-called unsightliness of poles and wires. In the early days of electric traction, there was certainly grave cause for complaint about this feature, but since then the improvements have been so radical that it has no longer great force, while the danger of falling wires and of obstruction to firemen in the discharge of their duty has also been done away with to a very large extent, so that there are to-day as few accidents of any kind from the operation of trolley cars in our principal cities as could possibly be expected in view of the immense number of passengers carried, and the congested conditions of the streets.

The surface contact, or "button system," is not in use on any large scale in this country, but a large installation has just been made in Monaco, which is said to be working successfully. The chief trouble with this system lies in the employment of a great number of pieces of mechanism more or less complicated, and liable to failure, the number usually being 500, at least, per mile of single track. Theoretically, the system is an excellent one and has many points of advantage, but it has not come into common use as yet, and time only will tell whether or not the mechanism can be kept in good working order indefinitely without constant danger of "tie-ups" or delays.

The open slot conduit system is in use in America only in New York city and Washington. In New York it has cost probably ten times as much as an overhead system would have cost to accomplish the same results, and its operating expenses are probably about the same as, or perhaps slightly less than, those of the equivalent overhead trolley system.

The city of Glasgow, Scotland, in common with many other British and European cities, has before it to-day the problem of determining which of these three varieties of electric traction shall be adopted. Glasgow has had some experience with the overhead system, and knows that it is reliable, reasonable in first cost, and economical in operation. The favorable results obtained on the conduit lines of New York, Washington and a few European cities, have been studied in Great Britain and elsewhere with the greatest care and interest, and yet it has been determined in Glasgow and other places to use the overhead system in preference to the conduit. The fact is that it is only in cities where great traffic density obtains, and where the mileage to be equipped is comparatively small, that it is possible to pay interest upon the enormous investment requisite for the conduit system, and this is particularly true if this investment has to be piled up upon that for previous improvements, such as the equipment of horse lines with the overhead system. Moreover, the climatic conditions must be favorable in order that success with any form of conduit system may be assured, and the sewerage system must be perfect, for unless the conduit can be kept perfectly clean and free from snow or accumulations of water, serious electrical troubles will occur, which may tie up a railway in whole or in part. If the street railways in this country now operating on the overhead electric system were compelled to change to the conduit system over their entire lines or any large portion of them, financial ruin would undoubtedly be the consequence.

All these problems of motive power have had to be faced by managers in this country, and are now before the tramway managers of Europe. They are wise in their generation who have looked, and are looking forward to the future of their properties and of the cities in which they are located, and who recognize the importance of the part which local transportation plays in the onward march of a great and constantly growing city. The real interests of the people and of the private capital engaged in street railroading are, or should be, substantially the same. The ideal system for both is one which can be handled with the greatest certainty in operation, and which can be indefinitely extended into suburban territory in advance of population without too great cost and without the necessity of transfers, and which can be built at minimum expense for the advantages given. It cannot be for the public interest to load down street railway companies with constantly increasing burdens, such as the adoption of the most costly forms of motive power, if cheaper would answer the purpose, for by doing so they thus postpone still further the time when any reductions can be made in fares or a system of profit sharing with the city can be established.

THE PROBLEM OF CARS AND CAR SERVICE

Upon the character of the cars and the car service of a street railroad depends largely the gross revenue which will be derived from the public. One of the key notes to success in handling street railway property is to bring about to the greatest possible extent "short distance riding." The number of times that a car can load up and empty itself upon a trip governs the success of that car from a profit-earning standpoint. For this reason it is essential that cars be run frequently enough to make them a convenience to those who would walk were not the opportunity of riding offered on the instant. But on the other hand, the frequency is limited by the number of people who could by any possibility be induced to ride. In practice the manager has to experiment with car frequency until he strikes that which will bring about maximum earnings, and at this point it is not far from the truth to say that the public is well served.

The car service must also be rapid, for the short distance rider takes a car not only because it is right at hand, but also because he can save some minutes in getting to his destination.

The car must be comfortable and well lighted, by windows in the day and by lamps at night, for the further advantage and attraction of the traveling public. Never has there been such attention given to the comfort and convenience of the people as in these days of electric traction. When the investments are large, the business required to maintain that investment must also be large, and the margin between success and failure is so small that an inferior or unpopular service means a loss of business sufficient to turn the scale. In some of the Western cities, St. Louis in particular, where several companies are competing for business in the same territory, there have been developed many novel and attractive types of cars to the advantage of the public if not of the companies. The carrying of traffic is so delicately adjusted in cities like St. Louis that oftentimes the appearance of ten or fifteen new and beautiful cars on a given line has meant an increase in receipts on that line of hundreds of dollars a day, and a corresponding diminution on the lines parallelling it. These other lines, finding it necessary, of course, to get back their traffic, have been forced to order even better and more attractive cars. In the old horse railway days, 12-ft., 14-ft. and 16-ft. closed cars with longitudinal seats, and six or seven-bench open cars with cross seats were in almost universal use, though many railways denied themselves and the public the luxury of the open cars. To-day cars range in length from 20 ft. to 40 ft., and a 16-ft. car looks almost as small and as much out of place as the old 10-ft. and 12-ft. cars of the horse railway era. With these longer cars has come greater steadiness in riding, and trucks have been greatly improved to the end of bringing this about. The West, always in advance of the East in obtaining beauty and convenience in railroad passenger trains, is somewhat in advance of the East also in street railway cars, and in St. Louis, Milwaukee, Denver, San

Francisco and elsewhere, will be found some of the most beautiful travel attracting street cars in the world, with cross seats, center aisles, broad windows, window guards, electric signals and elegant fittings throughout.

Somewhat strangely, perhaps, the almost universal foreign custom of providing roof seats on tramway cars has not been popular in this country, the reason appearing to be that such cars are better adapted for slow speeds than for high, and for countries whose peoples do not place upon time the same value that Americans do, for there is no question that it would be impossible to keep up the present schedule speeds on American street railroads if the cars were obliged to take time to load and unload passengers to and from the roof seats, while the danger of accident to people not used to climbing up and down the stairs while cars are in rapid motion would be considerable.

The manager or employee who lays out the schedules of a street railway has in his hand when doing this work the operating profits of the enterprise. If he is too niggardly with car mileage, he saves a little in expenses, but may perhaps reduce gross income by a far greater sum than the savings. If, on the contrary, he is extravagant with car mileage, he may increase expenses far more than income. The mean is indeed a golden one, and worth a never-ending series of experiments to determine the maximum traffic and profit possible to be derived from any given line. In more than one instance, a languishing or unprofitable enterprise has been turned into a vigorous and profitable one by the mere application of common sense principles to the car service.

THE PROBLEM OF TRACK AND ROADBED

The introduction of longer and heavier cars, a much more frequent service and a self-propelling power which needs to obtain a grip on the rails, has enormously increased the difficulties of the track problem for street railway companies, and on all sides are being heard complaints that joints are wearing out, rails are showing excessive wear in spots, leading to unevenness of track, and that the repairs and depreciation of roadbed for electric traction have been underestimated. The most heavily worked track and special work of the larger cities will stand hardly three years of service, and the life of electric track varies from this period to ten or twelve years as a maximum, according to our present experience. When it is stated that it costs from $10,000 to $25,000 a mile to replace track, it can easily be seen how serious is this problem, and how great a burden upon the finances of a company is the track repair and depreciation account. In the few places where street railway profits seem excessive, therefore, such burdens as these, which are yet, in all their seriousness, of the immediate future rather than of the present, should be remembered.

THE PROBLEM OF FARES

In this country a uniform five-cent fare is almost universal; in other countries a variable fare, based on distance traveled, is equally universal. There is something more than a mere financial policy involved in the discussion of the fare problem. Broadly speaking, a uniform fare means depopulation of the tenement house districts and settlement of the suburbs—means a clean, happy life in purer air and better surroundings—means individual homes and plenty of room for the children. A graded fare means enormous density of population in the heart of the city, scanty suburban settlements, pale faces, sickly children and a miserable home life for the masses. These words are not too strong, nor is the influence of street railway fares upon these living conditions exaggerated. The difference between the street railway track mileage and investment in our principal cities and those of equal size abroad is something amazing. Compare, for example, Brooklyn, Glasgow and Boston, three cities of about the same size. Brooklyn, with a population of about 900,000, within five-cent fare limits, has over 500 miles of track; Boston, with 700,000 population, has 325 miles of track; while Glasgow, with 800,000 population, has but 77 miles of track. The total street railway investment in Brooklyn is nearly $100,000,000, in Boston is over $25,000,000, and in Glasgow less than $4,000,000. The 800,000 people of Glasgow are distributed over but 23 sq. miles of territory, and the population in the city is therefore about 35,000 per sq. mile; Brooklyn's 900,000 inhabitants live in a 45-mile area, and have a population density of but 25,000 per sq. mile, while Boston's 700,000 inhabitants are happy in 122 sq. miles of area, with a population density of but 5700 per sq. mile. Is not the uniform fare principle justified by these figures alone?

For five cents a citizen of Brooklyn may travel more than 10 miles. A citizen of any of our great cities can travel 10, 15, or even 20 miles. In doing so he inflicts a loss upon the company, and if there were a large proportion of the total number of passengers carried who traveled so far, or even 5 or 10-mile distances, our city railway properties would be continually unprofitable and probably insolvent. It is in the short-distance riding that the losses are made up, and it must, therefore, in frankness be admitted that the short distance rider pays part of the fare of him who rides the longer distance. This is an apparent injustice, which cannot, however, be remedied unless the whole principle and policy of American street railroading be radically changed, and the effect of the change would be undoubtedly disastrous from a sociological point of view, tending to check the expansion of cities into the suburbs and increase the congestion of life in the centers.

Is the present five-cent fare too high, and can it be reduced without consequent disasters to street railway companies? Both these questions can be most emphatically answered in the negative. The street railway companies of to-day are giving to their patrons a maximum ride two or three times greater than that given for the same price ten years ago, and an average ride at least 50 per cent greater; they are giving them a speed in transit from 50 to 100 per cent greater, and are providing them with cars cleaner, finer, better lighted, and in all respects superior to the old regime. Is a mere change of motive power from horses to electricity a magical thing that can multiply wealth as by a philosopher's stone and make all things possible? No. The street railway companies of the country are by no means unduly prosperous to-day. In fact, too many of them are struggling under far heavier burdens than ever ought to have been put upon them by the people. In Philadelphia, for example, the right to change the motive power from horses to electricity has been granted on condition that the street railway company shall lay down new pavement and permanently maintain this pavement on over 400 miles of street within the city limits—a condition more onerous perhaps than that ever before laid upon a quasi public industry, and one which will make the payment of excessive dividends or a reduction of fares impossible for many years to come, if not forever. Take twenty of the great street railway properties of the country, none earning less than $1,000,000 gross per annum. Their aggregate capitalization in bonds and stock outstanding is nearly $500,000,000; their aggregate gross receipts are about $67,000,000; their apparent operating expenses (including taxes) are about $42,000,000, or 63 per cent of the gross receipts, and the percentage of apparent earnings from operation amount to barely 5 per cent on the total capitalization.

"But these properties are overcapitalized," it will be said.

Admitted.

Suppose I assume, too, for the sake of the argument, that the overcapitalization is 100 per cent—that the real accumulated cash investment in all these particular properties is not $500,000,000, but $250,000,000. This certainly would seem to be an assumption sufficiently sweeping to suit any critics, and is far larger than the fact.

As a result we have apparent net earnings equivalent to a return upon investment of 10 instead of 5 per cent. Is this larger figure too great for risks so serious as those which have to be taken by investors in street railway properties?

But this is not all. These twenty properties are not now in reality earning 5 per cent on their $500,000,000 of their capital liabilities, or 10 per cent on half this amount. They are knowingly or unknowingly deceiving themselves in the matter of maintenance, and some day there will be a reckoning in consequence. In other words, their percentage of operating expenses to gross receipts is much more than 63 per cent, and perhaps hardly less than 75 per cent, and they are probably earning on an average but 4 per cent or less on their capitalization.

THE PROBLEM OF TRANSFERS

To most people, no doubt, the transfer problem appears a very simple one. Surely it would seem that no more just and reasonable demand could be made on a street railway management than that a passenger should be allowed to ride from any point within a city to any other for a single fare, particularly if the entire system is owned by one company, and if the city is a small one. It is on deeper investigation only that the real difficulties appear. Broadly speaking, it may be said quite certainly that hardly a street railway manager in the country would object to the simple proposition outlined above if that were all there were to the problem. It is not of serious importance to him whether a passenger complete his ride on the original car or on a connecting one. The trouble is found in limiting the use of transfers to their entirely legitimate purpose without running against sheer dishonesty on the part of the public, and on that of the company's own employees. The entire transfer problem is one of preventing this dishonesty and of nothing else. To prevent conductors from replacing cash fares with transfers is possible only by the most careful comparison of returns and records in connection with a more or less complete detective force, and the cost of this combined service is often very large. But a more serious trouble than this by far is found in the "swapping" of transfers by, for example, clerks in the same offices living in different parts of the city, or by

their improper use in other ways for return or continuation trips, and in the actual giving away or selling of transfers taken for that purpose at the close of the honest trip. There are not a few cities in which the routes are so peculiarly laid out as to make it practically impossible to put into effect a transfer system which cannot be thus tampered with to a most serious extent, while in all cities there is a more or less large percentage loss from illegitimate use. The fact that in nearly all cities of America the street railroad companies have conceded some form of transfer accommodation and are standing the consequent loss in receipts and in operating expenses, should be credited to them as a partial offset for some of the things which they have been obliged to refuse the public.

THE AVOIDANCE OF ACCIDENTS

In the operation of many cars through crowded streets of cities, it is inevitable that there should be accidents, trivial and serious, from the running down of a peddler's cart to the killing and maiming of a carload of passengers. The fact that the trivial accidents are so few and the serious ones so extremely rare in proportion to the number of passengers carried and to the number of obstructions, human and otherwise, in the streets, points to the remarkable care which is uniformly exercised by the employees of our great companies working under carefully established rules. During the year ending Sept. 30, 1897, the street railway cars of the entire State of Massachusetts ran 61,577,917 miles, and carried 308,684,224 passengers. The number of accidents of all kinds was so extremely small that the cars traveled on an average over 48,000 miles before injuring a passenger, and about 83,000 miles before injuring any one in the streets or highways through which they passed. The number of fatal injuries was only one for each 200,000 miles traveled. The number of fatal injuries to passengers was but one for each 30,000,000 carried. This is a marvelous record considering the character of the "rights of way" which street railways possess, and indicates the most careful attention to safety in travel.

Accidents may be minimized in number, first, by reducing speeds of cars indefinitely; second, by increasing braking power; third, by the introduction of some form of fender or protective device; fourth, by the selection of employees who will exercise care in the handling of cars, and fifth, by the education of the public itself to treat the cars with respect at all times. Speeds will increase rather than decrease, for the constant effort is and will be, in America at least, to save time at the expense of concurrent disadvantages such as even that of injuries to passengers and wayfarers, and if the proportions do not rise to extraordinary figures, the public will not suffer the carelessness or misfortune of the very few to interfere with the advantage of the immensely greater number. The remedy must be sought, therefore, in the other directions named, and will, as a matter of fact, be found in the combination of all. The public, whether on foot or in vehicles, is daily learning to keep out of the way of street cars, and the lesson of the true economy of good employees has been well learned by street railway companies. No entirely satisfactory braking system of general application has yet been found, but the power of mechanical brakes has been enormously increased since the advent of electricity, while air and electric brakes for the higher speeds of interurban work have been developed, not perhaps to the highest point possible to reach in future, but to one of present commercial and effective value. Fenders are yet a necessity, though a troublesome one, and it is hard to see how their use can be avoided even with the best braking appliances.

THE MANAGEMENT OF EMPLOYEES

It is within the power of the street railway manager to exert an influence for good or for evil—towards better things or worse—in the lives of hundreds or thousands of employees. He can arrange their hours so as to keep them constantly on the move between home and work, or so as to give them long free periods of time within desirable hours. He can harass them with a multitude of rules, or deal with them as reasonable beings with comparatively few rules. He can make them loyal and enthusiastic in the service of the company, or disloyal and indifferent to its interests. Upon his treatment of employees depends the success of his administration more than upon any other of its features.

The new street railroading of to-day has brought into service a much more intelligent grade of employees than was found in old horse car days. Then it was only necessary that a driver should be able to handle horses with reasonable care and to maintain the schedules through the streets. The conductor was watched with the most jealous care to prevent dishonesty. Uniforms were rarely seen, and the morale of the men was undeniably poor.

To-day, the entire force of employees, particularly in the transportation department, is composed of trained men, neatly uniformed and with quick and intelligent minds. They are, and must be smart, "snappy" and businesslike in the conduct of their work. The conductors and motormen must know many things about their cars, which were never required from the horse car force, since blockades must be prevented and the road kept in operation at all hazards. As a consequence, the present employees can be made to feel proud of their work and their opportunities. The organization is more complicated, the chances for promotion are better, and the conditions are in all respects improved. The most successful managers of to-day have put their systems far beyond the danger of strikes by making friends with their men, and putting certain influences into play among them, which enormously increase their *esprit de corps*.

The most important of these influences perhaps is that of increase of pay with length of service. In the old days, the wages of a conductor or driver were no greater to the man of twenty years service than to the six months fledgling. All were treated alike, the theory being that the *work* was the essential thing, not the *man*. As a consequence, disaffection was easy to create in a body of employees. The long service employee felt, indistinctly perhaps, but none the less certainly, the injustice of putting him on a level with the new man, and felt, too, that there was nothing for him to look forward to in the future. All men were equal in the labor meetings, and a knot of the disaffected could sway the entire body of employees.

It is easy to understand the restraining influence brought about by the adoption of a graduated wage scale in a body of employees of this character. Suppose, for example, that this scale runs from $1.75 to $2.25 per day, the minimum being received for the first year's service, and a five-cent per day increase being granted for each subsequent year, so that only after ten years' service will the $2.25 rate be obtained. We have, therefore, in such a force, ten different bodies of men, each growing better and better satisfied, and more and more conservative as the years go by. Each takes a pride and pleasure in every increase of pay, looks forward to still better things, and considers the entire wage scheme reasonable and just. The chances for disaffection are confined to the newer men and the influence of all the others is a restraining one, not only because of their self-interest, but also because of their longer experience with the company's methods and the consequent value of their advice. In the remote contingency of a threatened strike, the employees cannot go before the public with as strong a case as they could were the average wage rate $1.75 or $2; for example, since the company can show that it is really paying the higer wages demanded for experience and ability, and it is the new and untried men who are making the trouble.

Another influence of much the same general character is the adoption of the "service stripe" plan of recognizing length of service. The man who carries on his sleeve one, two, three or four stripes, signifying an equal number of years of service, or one or more gold stripes, signifying five years each, feels the responsibility of his position, and feels a self respect which shows immediately in his care of the traveling public, and which in turn commands respect from that public. He is identified with that company, its interests are his and will be guarded. The officers of the company themselves should have, and do have, as a matter of fact, great respect for the older employees, and the entire force, from the president down, is welded together more and more closely as the proportion of the long service men increases.

Still another good influence among the men is that of promotion to positions of higher responsibility, and the sooner street railway companies realize this and put the principle into practice, the better will be the results they obtain, and the more nearly will they approach the stability and strength which the railroad industry has gained by the security in tenure of office and chance of promotion which has been for many years granted to railroad employees.

The principle of competition in the conduct of the street railway business has not as yet been introduced to nearly the extent that its value warrants. In the maintenance department, for example, piece work as against time work could probably be adopted with considerable advantage. A man will always work harder and more intelligently and adopt better labor-saving methods if the fruits of his work are to be given him in greater remuneration, and while careful inspection of such work is, of course necessary, the conditions under which street railway repairs are carried out are such as to make such inspection feasible and efficient. The experiment has been tried in one or two cases with excellent results.

Another place where the competitive idea can be introduced is in the management of the power used by cars. It is well known that motormen, as a rule, waste power enormously by the improper handling of controllers. In many cases this is done carelessly without much thought of results. In others it comes from a disposition to play with the immense force at the command of

the motorman by the mere movement of his hand. The results of this misuse of the controller are seen not only in the power cost, but also in increased depreciation of motors through constant use of excessive currents. Now the very simple plan of placing in each car a wattmeter to measure the power which is used by that car, and of taking regular readings of this wattmeter at the end of each run, has accomplished in one or more instances, and would accomplish in practically all, remarkable results in the saving of power and of depreciation, for the moment that a motorman is called to account for using more power in going over a route than another motorman uses, that moment he begins to be more careful. In one case recently made public, a saving of 33 per cent in the cost of power was effected by this simple method.

The street railway employees' associations, with their corresponding club-rooms, gymnasiums, baths, libraries and monthly and annual entertainments, together with the provisions for death benefits, etc., tend to bring the management and the men into closer union, and are always to be encouraged as valuable adjuncts to the regular work. The library feature, which has been lately introduced on at least one large system, brings the home influence into play in behalf of a management, tending, however slightly, to cause the women of the family to exercise a restraining influence over the men in times of threatened strikes.

Broadly speaking, the modern street railway management, as distinguished from the older forms, brings men into closer communion with the official staff and creates in them a self respect and manliness of character which is the best possible security against trouble. Those managers who have adopted these broad gage methods and have been genuinely solicitous for the well being of their men, have been successful to a remarkable degree in securing the personal loyalty of the latter, and in strengthening their own position and that of their company in the community.

THE ADVANTAGE OF COMBINATION

The public gains, or ought to gain, with combination of municipal service enterprises. No principle in practical sociology is better established, perhaps, than that which grants to public service industries in municipalities the right to be regarded as "natural monopolies." It can never be to the permanent advantage of the people to have two lines of street railway serving the same territory on the same or parallel streets, while it is a distinct disadvantage to have separate companies serving different sections of the city. A transfer system between independent companies is an impossibility on any fair basis, while the almost universal result of a consolidation of several different companies in a single city is the immediate granting of transfer rights, and an immense saving to the people. This one advantage alone is a sufficient *raison d'etre* for consolidation, but in addition to this there are others. The entire transportation of a city can be operated by a single company on broader lines and to the far better service of the people than can be done by two companies. Economies can be introduced and more liberal expenditures in other directions made possible, through routes can be established along the lines of customary travel, and in many other ways the people will be benefited.

The economies effected in the street railway administration are numerous. Instead of several power stations, one or two of the best ones only may be kept in service and the cost of generating and distributing the current may be minimized. A better service may be given with a smaller number of cars than before, the official salary list may be reduced, the principle of division of labor may be introduced into shops, repair force, etc., and the day when fares may be made lower to the people will be brought distinctly nearer.

There is also much to be said in favor of the consolidation of street railway and electric light and power interests. The great difficulty with electric lighting stations to-day—a difficulty which is keeping up the price of light and power to materially higher figures than ought to be possible of attainment—is the fact that the stations can be loaded up to their capacity for but a few hours out of the twenty-four. This puts the working forces to a disadvantage, leaving them comparatively idle for many hours, and reduces the economy of the engine or leaves a part of the plant idle, which thereby earns no interest upon its cost. If the market for power can be increased and the loads distributed fairly evenly over the day, the cost per unit of power delivered will be far less than at present, and the price can be correspondingly reduced. The consolidation of all electric power using interests will tend to bring about this result, and is therefore to be favored on the grounds of public as well as of private gain.

THE PROBLEM OF MAKING A FAIR BARGAIN WITH THE CITY

I have purposely left this most important problem till the last because it is only through a more or less clear understanding of the nature of the other problems hereinbefore discussed that the true character and difficulties of this one can best be understood. There are, and will unfortunately continue to be, a great many false theories and ill-advised schemes put forward to solve the problem of how to best handle municipal service enterprises and to relieve the tension now existing between municipalities and private companies. The truth is that there is no one method of universal application. It is as foolish to assert that municipal ownership of everything in sight will bring the millennium immediately as it is to hold that municipal ownership has no place whatever in the management of public service enterprises. There is a sharp distinction between that class of services which a city has to itself use in whole or in part, such as, for example, sewerage, water supply, gas and electric light, etc., and that class which it does not use, such as transportation. An attempt to control the former class may be defended on the ground of wise economy in city expenditures. An attempt to control that latter has for its basic purpose an idea either of obtaining revenue by indirect taxation or of giving a service to the people at actual cost.

Under all circumstances and with all kinds of enterprises, it is true that municipal corporations, in which responsibility for results is so greatly subdivided, cannot, theoretically, and do not, historically, conduct business enterprises with economy or efficiency, while even more important than the question of mere money saving or waste comes the undeniable fact that the trustees of municipal funds cannot possibly manage these funds on broad lines, or with the calm confidence in the future justification of present expenditure that private capital would have. The taxpayers would not suffer the imposition of present burdens for the benefit of posterity, at least without a storm of criticism which would render the positions of the trustees difficult or untenable.

The transportation enterprise, particularly, is one where investment must be made without regard for present profit if the growth of the city on right lines is to be kept up. For this reason and entirely independent of the mere question of possible revenue to be derived by a city from the operation of its street railway system, I believe firmly that it would be utterly unwise to place the control of a city's transportation agency in other than private hands. I believe that in practically all cases the true solution of the problem of relations between a city and its street railway system is found in granting to the latter private ownership and operation, complete monopoly, perpetual franchises and a system of perpetual profit sharing with the municipality, joined to a remission of charges to the public if, and whenever profits come to be sufficient for that purpose.

By a policy of this kind it is possible:

1—To avoid pledging the city's credit for making the necessary original investment.

2—To place upon private capital the burden of all losses realized or contingent.

3—To obtain for the city an equitable share of all profits actually realized.

4—To avoid the creation by the city of a complex bureaucratic organization with its attendant political dangers.

5—To secure for the benefit of the municipality, its people and the private capital invested the undeniable benefits of private management as affecting profits, perfection of service and direct responsibility.

6—To secure for the municipality, the people and the private capital invested, the true pro rata shares of each in the additional profits coming with municipal development in the future.

When all the safeguards possible to devise shall be thrown around a municipal contract of this character, it will be found that the street railway problem in that particular city is solved for all time, and in a fair and equitable manner. Thenceforward the municipal government and the street railway corporations will work *together* to build up and develop on its broadest lines the municipality of whose interests they are, at once, guardians and servants.

Electric Traction and Its Application to Suburban and Metropolitan Railways *

BY PHILIP DAWSON

There are practically three methods of handling electrically the traffic on a railway, namely:

1. By locomotives or motor cars hauling a train of trailer cars.
2. By independent motor cars.
3. By a set of independent motor cars formed into a train and handled from the front car or from a so-called controller car. Each car, however, can be separated from the train, and it then becomes an independent motor car.

* Abstract of paper read before the Society of Arts, London, March 21, 1899.

As regards the supply of the necessary current for the motors, there are three distinct methods:

Firstly. By accumulators or storage batteries which may be carried either on the motor car or locomotive, or on a tender.

Secondly. By having a car containing a stationary engine, dynamo and boiler, which supplies the necessary current to the motors on the cars comprising the train of which it is part, and as proposed by W. Heilmann.

Thirdly. By continuous or multiphase current supplied directly from a generating station or from a sub-station which, in its turn, gets its supply of energy from the main station, the current being distributed either in the form of direct or polyphase to conductors running along the lines, and from which the power is supplied, through sliding contacts on the cars to the motors.

The two former methods, as far as this paper is concerned, will not be discussed, as sufficient data are not available to justify their being considered.

The system of transmission of energy to the motors by means of conductors laid along the track, will therefore alone be considered.

This method allows of several variations as far as the generation and distribution of power is concerned, amongst which the chief may be set down as follows:

(*a*) One continuous current generating station supplying current direct to contact rail. Where drop in pressure owing to distance becomes excessive, a negative "booster" may be used—it serves, so to speak, to pump back the current to the station, and is self-regulating, not taking at any period more power than is actually required to pump the current back. Should there be one or two lines too long to enable them to be worked this way, polyphase high tension generators should supply the power to one or more sub-stations along the line, as may be found necessary, in which rotary converters are located, which transform the current back into continuous. The polyphase generators to be driven by continuous current motors in the generating station. As an example of such a station, the new Dublin tramway power house may be taken.

(*b*) One central station generating continuous current with sub-stations in which accumulators are located along the road, and which are charged by means of a booster and special cables. As an example of this system, the Leeds tramways may be taken.

(*c*) A series of stations, as described under (*a*) and (*b*), situated at various distances and connected together one with the other. As an example of this, the tramways and light railways in and round Boston, Mass., may be taken, owned by the Boston Elevated Railway Company, which has absorbed the well-known West End Company.

Data of Boston Elevated Railway.

Track miles operated	305
Number of cars	2,648
Car miles run during 1898	29,787,000
Passengers carried during 1898	172,764,300
Number of power stations	5
Total capacity of power stations in kilowatts	16,100
Total rated indicated horse power of engines	24,000

(*d*) A power station generating polyphase currents, which, by means of static step-up transformers, are transmitted at tensions which run from 2500 to 40,000 volts to sub-stations where static step-down transformers reduce them to pressures of 300 to 350 volts, the current at this pressure enters rotary transformers, which deliver direct current at 500 to 550 volts to the line. As an example of this latter system, the Central London Railway, which is now under construction, may be mentioned.

(*e*) A three-wire system with continuous current, the rails or return forming the neutral wire. This has been tried and found wanting, and the engineers of the Central London Railway most carefully investigated its possibility and decided in favor of polyphase transmission and rotary converters, and rightly so.

From careful calculations and the investigation of what has been done both in Europe and America, there is no getting behind the fact that for any power station which will exceed 4000 kw. in capacity, the polyphase system is nearly certain to prove commercially the only admissable one. This statement is upheld by such an authority as H. F. Parshall, M. I. C. E. It is evident that in the particular cases at present under consideration (suburban and metropolitan communication), more than 4000 kw. will be under consideration, and therefore nothing, as far as the power station and transmission is concerned, but polyphase currents will be considered.

There are two distinct varieties of service to be catered for. One that on a system like the Metropolitan and District, where the stops are frequent and the runs short. The other the case of long distance lines with few stops. In the present paper it is only proposed to consider the first variety. In this case the use of polyphase motors need not be considered, as for work entailing frequent stopping and starting they have not up to date proved satisfactory.

A short examination of the importance of rapid acceleration on lines having stopping places at short intervals is interesting. Practical experience with electrically-driven motor cars, or locomotives on the experimental track of the General Electric Company, at Schenectady, has proved that it is perfectly feasible to attain a speed of 30 miles an hour ten seconds after starting from a standstill. Assuming a level track, and that during sixty-five seconds the current is cut off, and the train allowed to coast, that the brakes are then put on, the train will be brought to a standstill fifteen seconds later, and the total time from start to stop will be ninety seconds. Under these conditions it will be found that the average speed will have been 23.16 miles an hour, and that the total distance run will be about .55 of a mile. Assuming that instead of attaining the 30 miles an hour in ten seconds, it took thirty seconds, and that this full speed of 30 miles an hour was kept up for forty seconds longer, and the brakes then put on, the train would be brought to a standstill in ninety seconds, and the average speed would work out as 21.66 miles an hour, or an average speed of about 10 per cent less than in the previous case, the consumption of power, however, being much greater.

It is evident that the most important point is to attain a high average speed, and to keep the maximum speed attained as low as possible, as by so doing less power is required in braking the train, and also less power is required to run the train. The time between the moment when the maximum speed is attained, and when the brakes are put on, should be at least from four to six times that required for stopping the train, so as to allow for errors in judgment on the part of the driver, and also to enable him to make up lost time. On the Manhattan Elevated Railway, in New York, the trains which are drawn by steam locomotives take twenty seconds to attain a speed of 14 miles an hour, or less than half the speed in double the time as compared with electric traction just mentioned.

A much larger current will be required to attain a rapid acceleration than to attain a slow one, but the current will be required during a much shorter time, and the total energy supplied will be less in the case of rapid than of slow acceleration. This fact must not be lost sight of when calculating the feeders for such a system, and the train service should be arranged in such a way that as few trains as possible start together. Furthermore, the more rapid the acceleration required the larger will the motors have to be, and therefore there will be a limit, above which it will not be advantageous to push the rapidity of acceleration. In new tunnel lines, such as are now being constructed all over London, it will be evident that it is an advantage to have the stations built with a down-grade for the trains to start, so as to help the motors and reduce the current required at starting, and that similarly it will be an advantage to have an up-grade when nearing a station, so as to reduce the amount of power required in braking. By properly choosing these gradients it is found that a total economy of from 40 to 50 per cent in the total power required by a train may be made. According to Mr. Potter's tests it was found that during acceleration an average power of 32 amps. per ton of weight of train was required.

From a comparison of the actual results obtained on the elevated electric railways of Chicago and on the Metropolitan & District line in London, we see that whereas the maximum speed of 25 miles an hour is obtained in ten seconds with electric traction, it takes thirty-three seconds to do it with steam locomotives—and that whilst the electrically propelled train could do the distance of 1880 ft. in sixty-six seconds, with steam it would take ninety-three seconds, or nearly half as much time again. If in the case of electric traction the power is cut off the moment the maximum speed of 25 miles an hour is obtained, and the train allowed to coast before the brakes are put on, the distance considered would be done in seventy-six seconds. The steam-driven train even then would take more than 25 per cent more time to do the same distance.

Having tried to show the advantages which electric traction possesses as regards the possibility of increasing the frequency of the trains without decreasing the factor of safety, namely, the distance between two trains, it may be advantageous to see how, from an economical standpoint of generating power, electricity is a cheaper method of operation than steam locomotion. An electrically-driven train only requires one man instead of two to drive it, and when the train is not running no power is consumed and no coal or water wasted. Steam locomotives, it is well known, use but very little less coal and water when they are standing still than when they are running, and are much less economical, consuming, as they do in America, from 5 lbs. to 6 lbs. of coal per i.h.p. On main line English roads it is stated that 3 lbs. to 4 lbs. are consumed, and taking an average power of 400 h.p. per locomotive,

and a train plus engine weighing 250 tons, at a speed of 40 miles an hour, we get at the most economical rate about 0.65 lb. of coal per ton mile, or compared to the electric power required by electric traction 13 lbs. of coal per Board of Trade unit required, which is enormous—under favorable conditions it would not take much over 3 lbs. of coal to give one Board of Trade unit at the switchboard. A properly designed electric station with large units would probably never consume more than 2 lbs. of coal per i.h.p.-hour, or 2.65 lbs. per kw.-hour at the switchboard, and engines of the size of 4000 to 6000 h.p. would be guaranteed to consume not more than 12 lbs. of steam per i.h.p.-hour. A large station would fully justify a comparatively large initial expense in coal handling and stoking machinery, and the location of the station could be chosen so as to be most advantageously situated as regards both coal and water, the coal without being handled being taken from either the ship's hold or the railway truck, conveyed automatically to the coal stores, and from thence automatically to the fires, the ashes being conveyed away automatically as well. In such a station but very few men would be required, and the cost of power could be reduced below one halfpenny per Board of Trade unit, including expenses of every kind.

Comparing again the coal consumption per train mile on large English main line railways, which varies from 35 lbs. to 58 lbs. of coal per train mile, we get a coal consumption of from 0.146 lbs. to 2.32 lbs. per ton mile, corresponding to 28.12 lbs. to 46.4 lbs. per Board of Trade unit, required to be generated at the power house. The following results actually obtained with slow speed Corliss type engines and standard American railway generators, may be of interest:

Total coal consumed, Brooklyn City Railway Company, per Board of Trade unit, 3 lbs.

Total cost, everything included, of Board of Trade unit at switchboard, 00.5195 cents (about one farthing).

Cost of coal per unit, 0.2307 cents, about 0.166 of a penny; Union Traction Company, Philadelphia.

Poorest coal, 3½ lbs. consumed, per Board of Trade unit at switchboard.

In another case cost of coal, 0.272 cents per Board of Trade unit at switchboard, about 0.186 pence.

Total cost of unit, all included, 0.591 cents, about 0.296 pence.

Coal consumption in another case with Corliss engine, average for one year, per i.h.p.-hour, 1.65 lbs. to 1.76 lbs.

What good slow speed Corliss engines, properly designed for railway work, compared to other engines mean are shown by the fact that by such a change in a large American station the coal consumption was reduced from an average of 8.3 lbs. to 4.9 lbs. of coal per car mile.

From a series of figures obtained from the various Chicago electric overhead lines, from 0.16 to 0.135 Board of Trade units are required at the switchboard to drive the trains, the average speed of the trains being 13½ miles an hour, and the maximum speed obtained varying from 28 miles to 35 miles an hour.

The coal and water consumption, per Board of Trade unit, must necessarily be very low, the losses in the step-up and step-down transformers and in the transmission and rotary converters would not be very great, and it would be perfectly feasible to attain an efficiency of 60 per cent at the motor terminals and of 50 per cent on the power applied to the car axles. Large engines and large generators and converters are designed so as to take an overload of 25 per cent for any period of time, and be capable of overloading 50 per cent for a short time without injury, and by a selection of proper units a very large economy could be attained.

It may be interesting to mention a few details regarding the two large power stations which are now being equipped in New York, and which will operate the two large tramway systems of that city, namely, the Metropolitan and the Third Avenue. The Metropolitan station is now under construction, and will contain eleven direct connected sets each of 3500 kw., room for extension being allowed, and a capacity having been foreseen of nearly double that amount. The following gives the particulars of the General Electric Company's dynamos which will be used.

The machine will have a frequency of twenty-five cycles per second, at 6600 volts. It will have forty poles, and will run a speed of 75 r.p.m. It will be of the stationary armature type, the core being built up of laminations 0.14 in. thick. Each lamination has two dove-tail projections which fit in corresponding slots in a heavy cast-iron spider. Spaces are left between the laminations at intervals through which currents of air are driven by the rotating field and circulating by intimate contact with core and windings. The armature winding consists of form-wound coils placed in slots in the core and retained by wooden wedges, the edges of which fit into recesses in the teeth. The field frame consists of a cast-steel ring supported upon a cast-iron spider, to this are bolted laminated core of sheet iron, the pole pieces of which project over and support the copper field windings. The field winding consists of copper strip wound on edge with paper insulation between turns. The insulation is such as to stand a test of 4000 volts alternating between the winding and the core. The exciting e.m.f is 125 volts. The collecting rings are of copper, and carbon brushes are used. The armature winding is tested to 12,000 volts alternating. The temperature rise of the machine after ten hours' run at full load is well under 40 deg. C. The efficiencies are as follows:

	Per Cent.		Per Cent.
1¼ load	.90	½ load	.92.5
Full load	.95.5	¼ load	.88
¾ load	.95	Inherent Regulation	9

The steam engines which drive these dynamos are cross compound Allis vertical engines 46 ins. high and 86 ins. low pressure cylinders, and 60 ins. stroke. They will develop 4500 i.h.p. at the rated economical load, and will be able to work continuously at 6000 h.p. if required, and for a short space of time they are to be able to work at 7000 h.p. The crank shaft is of solid steel, bored and forged, with a hole 16 ins. diameter the entire length, and it is 37 ins. in diameter where the wheel and armature are located. The diameter of the shaft in the bearings is 34 ins., and the length of the bearings 60 ins. The fly wheel will have cast-steel centers, and the rim will be built up of steel plates riveted together. The rim will weigh 225,000 lbs., and the engine itself, complete, about 600 tons, and it is believed that as good results as 12½ lbs. of steam per i.h.p. will be easily obtained. There will be several substations in which will be located step-down transformers of 300 kw. each, which will lower the voltage from 6600 volts to 350 volts. At this pressure the current will enter rotary converters of 900 kw. each, and will be delivered in the shape of a continuous current of 500 volts to the tramway system.

This company operates some 250 miles of tracks and carries approximately 250,000,000 passengers every year.

The Third Avenue Road is now engaged in equipping all existing horse and cable lines with electric traction, and for this purpose has just given out a contract for a power station which will eventually contain sixteen 3000-kw. generators. The generators will be very similar to those described above, and are being built by the Westinghouse Company, who are the sole contractors for the whole work. The engines will be marine type, vertical, and are being built by the Westinghouse Machine Company. Substations with rotary transformers will be used, as in the case of the Metropolitan system.

To give an idea of what may be done as regards power transmission the following few figures may be useful. The first attempts at this class of work were made during the Frankfort Exhibition of 1891, 300 h.p. being satisfactorily transmitted a distance of 106 miles with a pressure of 30,000 volts. Since that time electrical power transmission has largely increased, and the results obtained have been very satisfactory, 4000 h.p. at the present moment are regularly transmitted a distance of 85 miles to the city of Sacramento, Cal., at a pressure of 30,000 volts, where they are transformed into low pressure three-phase and continuous current for lighting, power, and traction purposes. At Telluride, Utah, 1000 h.p. are transmitted 55 miles at a pressure of 40,000 volts; 4500 h.p. are transmitted a distance of 40 miles to Salt Lake City at a pressure of 15,000 volts; 1400 h.p. are being transmitted 35 miles to Fresno, Cal., at a pressure of 11,000 volts; 2000 h.p. are being transmitted 30 miles to West Kootenay, British Columbia, at a pressure of 20,000 volts; 10,000 h.p. are being transmitted from Niagara to Buffalo, a distance of 22 miles, at a pressure of 10,000 volts. All the plants are working and giving satisfaction, and have nothing experimental about them, and there are hundreds more such.

In the designing and carrying out of a large system, there are three points which are frequently overlooked and which may cause a disastrous failure. These are good and adequate bonding; thoroughly good insulation, both mechanically and electrically, and trucks suited for the work for which they are intended.

As regards the bonding, the bonds used should be flexible, but, at the same time, should contain no solder or brazed joint, and they should be expanded against the side of holes drilled in the web or foot of the rail, and held in place by pins. Bonds of this description, when properly applied, can be absolutely relied upon, the contact resistance of the bond with the rail not being greater than the resistance of the solid bond.

With regard to the third-rail insulators, very good results are obtained by using insulating bolts screwed into base plates which are fixed to the sleepers, cast-iron chairs being fixed to the head of the bolts to hold the rails.

Parallel in the Development of the Locomotive and Electric Truck

BY JOHN A. BRILL

There is a remarkable and interesting parallel to be found in the successive steps by which locomotive and electric trucks have been developed. The striking resemblance is found in the treatment of the frame. The frame itself was the outgrowth of the requirements of constantly enlarging lines of service. The first illustration in this article (Fig. 1.) shows a locomotive designed by George Stephenson and built in the year 1836. An elaborate illustrated pamphlet was issued by the manufacturers showing the engine in detail. It was considered the finest machine of the kind which had been constructed up to that time. Our illustration is taken from "Cassier's Magazine," which recently published an article in which much of this remarkable pamphlet was reproduced. The engine was probably the most perfect machine of its type sixty-three years ago. It was put together, so far as its frame was concerned, in the simplest and by the most obvious mechanical method. Rivets were used everywhere to hold parts together and the frame was made up of materials ready at hand in the market. This frame, with its wood filling, was of flat bars and plate iron jaws to hold the boxes. These jaws were put on as independent pieces. A multiplicity of parts riveted together formed what seemed to be a solidly connected whole.

The fundamental principles of construction involved in the frame of an engine of this kind had not been discovered. The controlling idea in its construction was maximum power and convenience of manufacture. In fact, the old locomotive builders worked with the same limited conception of the problem that many of the modern builders of electric trucks entertain. They take, as in the olden times, what comes to hand in the market as most readily available for construction. The similarity of ideas which exists between this ancient frame and some of the electric truck frames of the present day is seen in Figs. 2 and 3. These show a modern built up frame as put in a truck and likewise the same frame by itself. The numerous rivets and the use of the bar iron are obvious. It is true that in the modern truck the wooden packing pieces are replaced with iron blocks, but in other respects there is little difference to be noted. The relationship of the modern truck to the ancient becomes very striking in Fig. 3, where the truck mechanism is absent and only the frame remains.

The very first American locomotive engines were quite similar in design. The model of the first locomotive turned out by Baldwin, now in the office of the Baldwin Locomotive Works, shows a frame of wood. Wooden frames plated with iron were common, if not the rule in the early days of locomotive building. As long as speeds were slow and the work light, these composite structures answered the purpose. How small the internal stresses were may be judged from the fact that the boilers of the Stephenson engine carried only a pressure of 50 lbs. per sq. in. The cylinders were 8 ins. in diameter, and the greatest strain exerted on the piston rod could not have reached 6000 lbs. even in starting. During operation the effective pressure fell off to a surprising degree, and the greatest pull exerted by the piston rod when running rarely reached 3000 lbs. This probably measures the greatest strain experienced in any part of the structure.

Higher speeds and heavier weights made the inherent defects of composite riveted frames very apparent. In less than six years experience American locomotive builders found that such frames were not the proper foundations upon which to mount an engine. In the year 1840, the Baldwin Works were using solid iron frames and it was at that time that M. W. Baldwin was granted a patent for making the jaws or pedestals in one piece with the frame itself which was of wrought iron. This practice has been followed by all American locomotive builders to the present day. The ad-

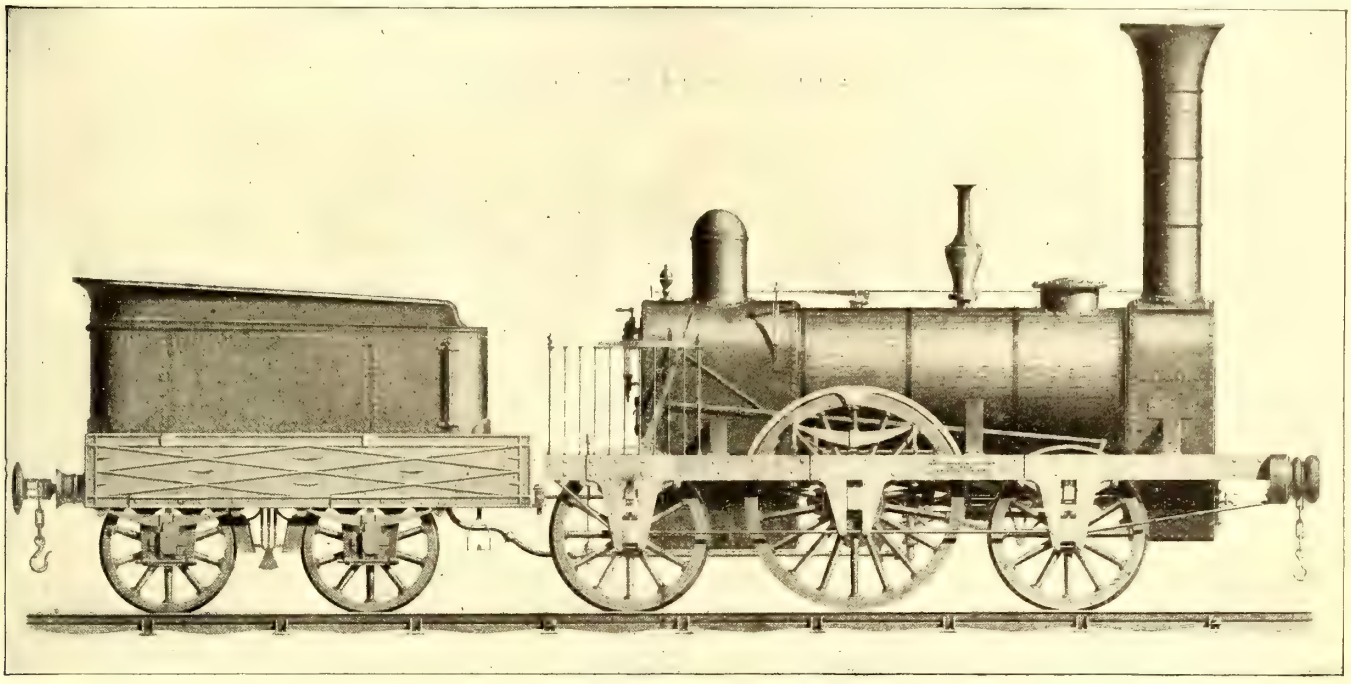

FIG. 1.—STEPHENSON LOCOMOTIVE BUILT IN 1836

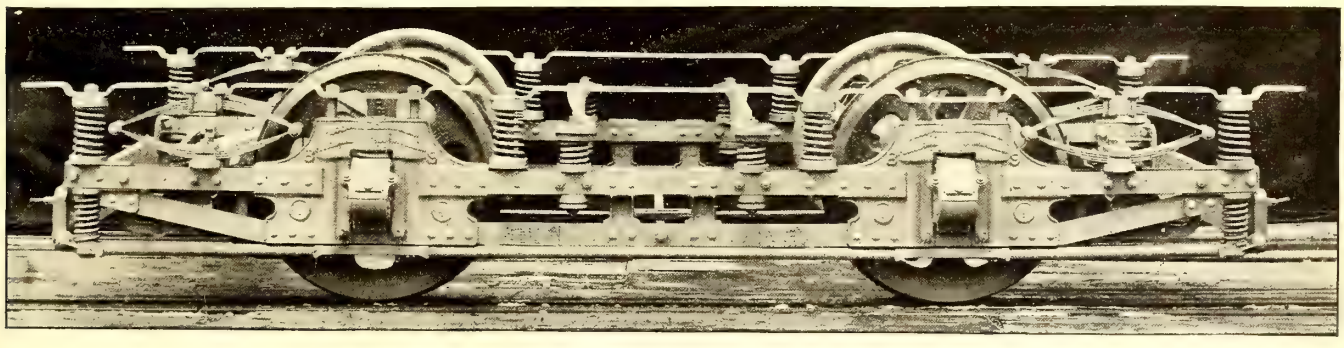

FIG. 2.—A MODERN ELECTRIC TRUCK WITH RIVETED FRAME

vantages of this form of frame were soon recognized and it was universally adopted in this country, only one locomotive builder adhering to the old plate frame for any length of time. His reason for so doing depended entirely upon manufacturing advantages having nothing to do with what was best and most mechanical for the purpose. As mechanical principles became better understood, it was seen that the solid frame was theoretically as well as practically right. The functions of the locomotive frame are simple and easily understood. It has to resist all the strains resulting from the operation of the machinery as well as those involved in the hauling of the train. It must sustain the load which strains it in a vertical direction, and, lastly, it must resist those forces which come into action when moving along the track. This includes the strains which are brought upon it when moving around curves and over irregular surfaces at the same time. In a word, it must be able to resist great strains which may be exerted upon it from all possible directions. Lastly, it must afford easy end for the attachment of the parts. The straight hollow cylinder for the least weight of material is the strongest of all geometrical forms for resisting strains from all directions. Difficulties of construction make them a form impracticable. The solid rectangular bar is the next choice since it has ample rigidity and its flat sides give facility for the easy and rigid attachment of the parts. A square hollow bar would, of course, be stronger for a given weight, but the difficulties of manufacture preclude its use. The American locomotive of the present day is essentially a rectangular bar of iron with the jaws forged into it. The points of the jaw are connected by tie bars, and the outer jaws usually have a diagonal bar connecting them with a prolongation of the main frame. The front section of the frame is usually a single bar of sufficient size and strength to resist all strain which may come upon it.

Fig. 4 is an outline sketch of the main portion of a frame made by the Brooks Locomotive Works for the latest type of six coupled, ten-wheeled passenger engines. Fig. 5 is an engraving of the engine itself. In the outline sketch the Brooks frame is shown from a point just behind the last or trailing axle jaw to a point just inside the cylinder seat. The great length and small scale necessary would make the details too minute to be seen had the whole frame been included in the engraving. It will be noticed that at the forward end a single bar is depended upon to do the work. These frames are neither of them a truss; their strength and stiffness are obtained from the substance and the quantity of metal which they contain. At the jaws where the strains are greatest, there is no attempt to truss or to maintain stiffness by means of braces. In Fig. 4 the inclination of the upper member between the first and second pair of driving wheels is merely an accommodation for the boiler. The bar at the forward end, which carries the cylinders, is a single piece of metal of immense size. This part of the frame could readily be formed into a truss if the truss form presented any advantages. As it does not, builders make it simply a massive bar.

The electric truck is a locomotive in its essential functions. It differs from the locomotive in having the additional duty of carrying a car body, and hence must be a carriage as well as a locomotive. The electric truck builders of to-day occupy a place relative to the art similar to the early locomotive builders. Like the early locomotive builders they are discarding the composite form after having, in their early efforts, given it an effective trial. Advanced

FIG. 3.—FRAME OF TRUCK SHOWN IN FIG. 2

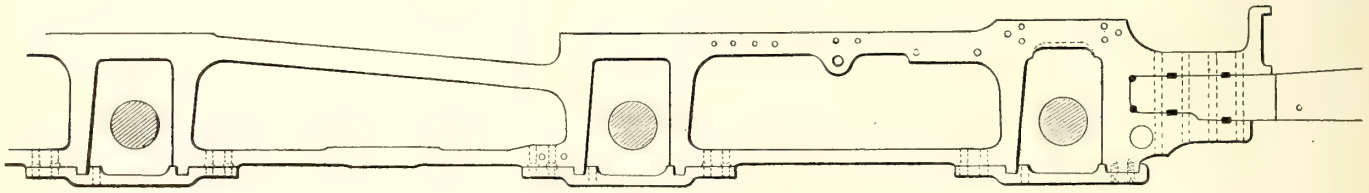

FIG. 4.—OUTLINE OF MODERN LOCOMOTIVE FRAME (BROOKS)

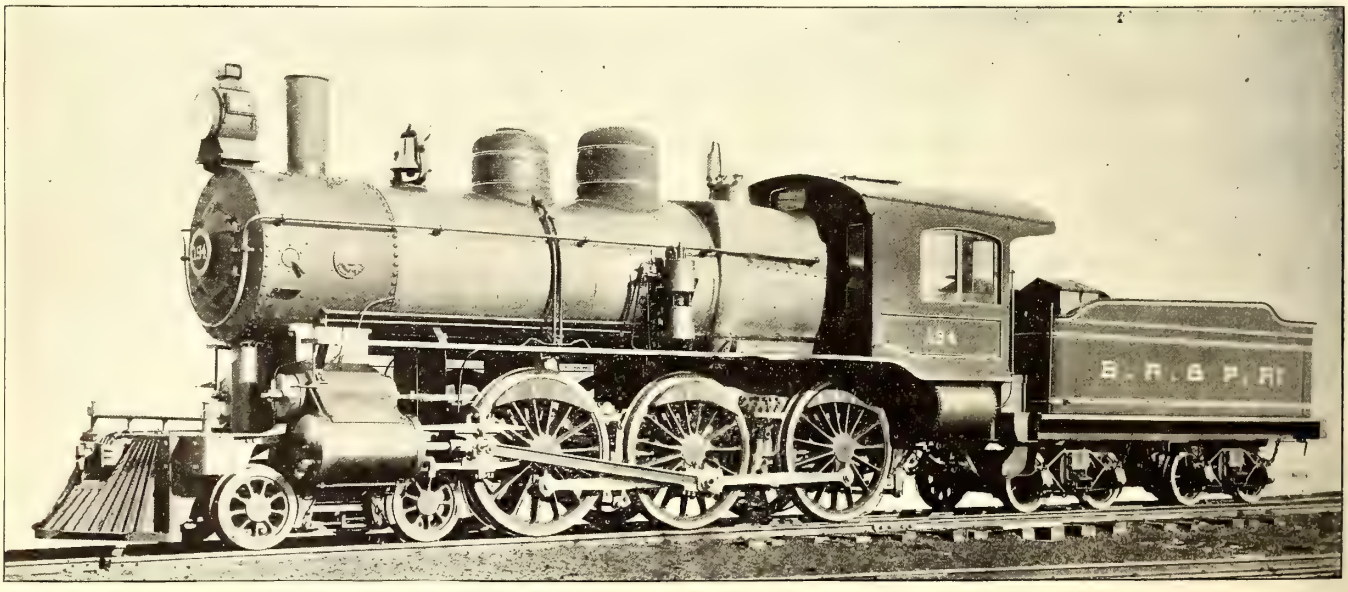

FIG. 5.—STANDARD BROOKS SIX-COUPLED TEN-WHEELED LOCOMOTIVE

electric truck builders have followed locomotive precedents in the introduction of a solid bar frame. A frame of this character by the Brill Company, of Philadelphia, is shown in Fig. 6, and the complete truck in Fig. 7. Like the locomotive frame, the metal is made sufficiently heavy to resist, without injury, all the strains that can come upon it. Comparing it with the locomotive frames, the similarity is at once apparent.

It is hardly surprising that the truss idea took such firm hold upon the builders who had thought of the subject in a superficial manner only. The truss is naturally the first thing that comes into the mind, because the load seems to be the most important factor in the problem.

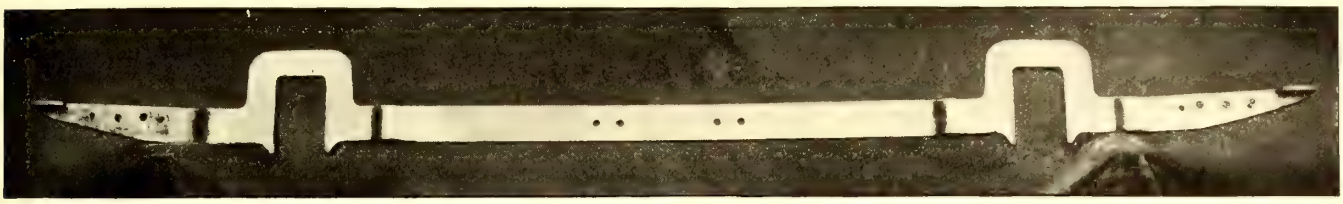

FIG. 6.—SOLID BAR FRAME

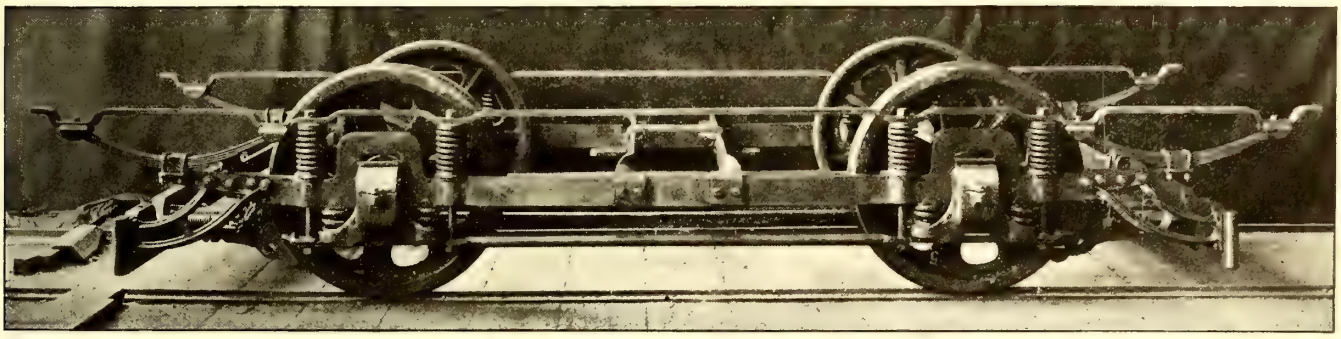

FIG. 7.—TRUCK WITH SOLID BAR FRAME

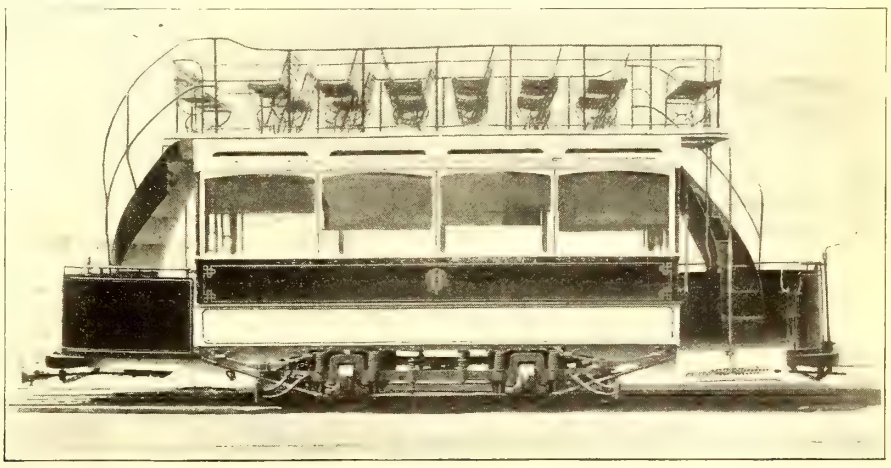


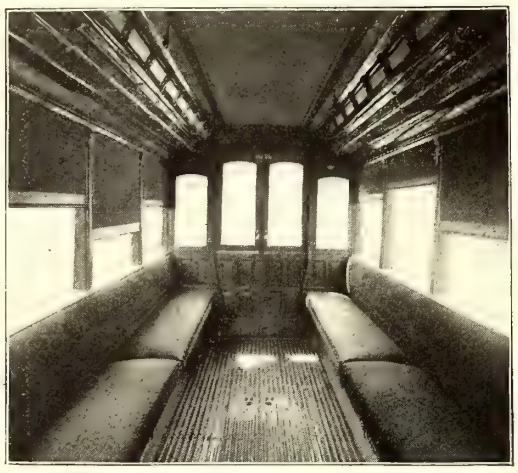
A little practical experience was required to show the fallacy of the idea, and it is surprising that it has retained its hold upon street railway men so long. It needs no study to prove a truss weak in all directions save one. It is a metal frame so disposed as to prevent the greatest resistance to a vertical load, with an entire disregard of strength in any other direction. In both locomotives and electric trucks the twisting and horizontal thrusts are often nearly, if not quite, as great as those exerted in a vertical plane by the load. There must be, therefore, horizontal as well as vertical strength. In addition to this, there is another element which is rarely given sufficient attention, the hammering and pounding of a locomotive or an electric truck upon the rails. This pounding destroys riveted connections with a speed which is quite surprising, and makes repairs frequent and expensive. This is undoubtedly one of the reasons for the early abandonment of riveted work in locomotive framing, and has also been an important factor in causing the composite frame to be regarded with disfavor in electric truck building.

Injunction in the Series Parallel Controller Case

The Thomson-Houston Electric Company and the General Electric Automobile Company on March 13, 1899, secured a preliminary injunction against the Detroit Citizens' Street Railway Company in the United States Circuit Court, Eastern District of Michigan, restraining the latter company from making, using or selling any combination of electric railway motors and motor circuits and resistance combined with controllers embodying the inventions or improvements recited in claims Nos. 20, 21, 22, 27, 28, 29 and 31, of Letters Patent No. 393,323. The principal claims of this patent were given in the STREET RAILWAY JOURNAL (American edition) for March, 1899.

Double Decked Car

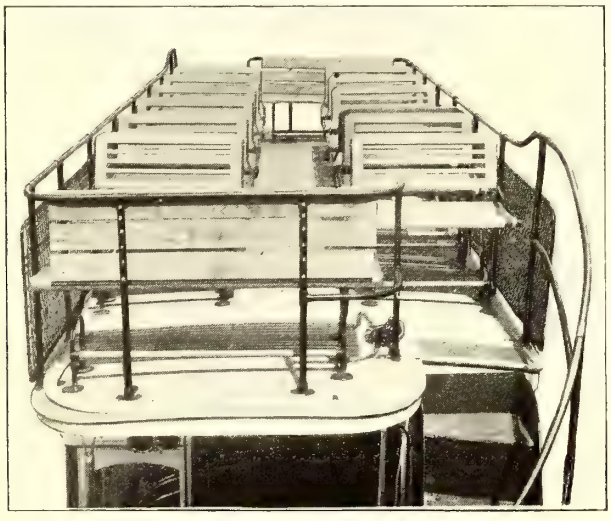
The J. G. Brill Company, of Philadelphia, has recently built a number of double deck cars for the Hull Electric Company, of England, which represented the very latest features of their type. The length of the body is 16 ft., the length over all about 28 ft., the width at sills is 6 ft. and the greatest permissible width but 7 ft. The platforms are rather longer than usual, being 5 ft. 6 ins



DOUBLE DECKED CAR—HULL

These cars differ from all those recently constructed in having fixed windows, and on this account the glass is of a large size and, of course, set without separate sash. The inside seats are longitudinal with spring backs and seats and are covered with carpet. Garden or "walkover" seats are used on the roof, with slat seats and backs. On the lower deck the car seats twenty-two persons. On the upper deck there are fourteen seats, accommodating twenty-nine persons, making a total seating capacity of fifty-one passengers. The cars are finished inside with three-ply maple ceilings and cherry over the windows. Spring blinds are used with the usual fittings.

Returning to the exterior view of the car, it will be noticed that the railing at the sides of the stairs is made much higher than usual to give greater protection to persons ascending or descending the stairways. At the sides of the upper deck, instead of having covering boards fitted to the rail, wire netting is used, giving the car a much lighter appearance than is usually found in English cars of this type. Galvanized gutters are fitted on each of the hoods. Red, green and white lights are arranged at the corners diagonally opposite the stairways. The trimmings are of bronze with bronze hand rail for the stairway. No. 90 Westinghouse



controllers are employed. By means of this the motors are turned into generators and form a brake by being short circuited through resistance. This brake is intended for emergency, but ultimately more resistance may be added and the use of the electric brake become more frequent.

The car is mounted on Brill No. 21 E truck. With the delivery

INTERIOR OF HULL CAR

of this order, there will be fifty-seven of this type of truck running in the city of Hull. There are two Westinghouse No. 46 motors for 500 volts and they are of the nose suspension style. The wheel

TOP SEATS OF HULL CAR

base is 6 ft., and the diameter of the wheels 30 ins. The Hull roads are of standard gage. One noticeable feature of this car is that of the unusual height which has been obtained in the center of the monitor deck, which is 6ft. 8 ins. from the floor. Angle iron bumpers are used with 6 ins. projection in front of the dasher. The cars are to be fitted with electric headlights. The platforms are dropped 6 ins. below the floor of the car, thus bringing the steps conveniently low.

A Handsome Catalogue

A handsome album of electric railway views has recently been issued by the Siemens & Halske Aktien Gesellschaft. It contains photo-engravings of many of the railway installations made by the company, as well as a complete list brought up to Jan. 1, 1899, giving detailed technical information of each road. These include both street railways in Budapesth, which are equipped partly by the trolley and partly by the underground conduit, and have employed the latter since 1889, the Franz-Joseph subway road in Budapesth, tramways in Switzerland, Italy, Russia, Holland, South America and China, mountain electric rock railways and mining roads. The cities in which the company has railway installations in operation or course of construction are in forty-six different States or countries.

Among the roads upon which construction is under way include the Berlin Elevated Railway, the complete tramway systems in Frankfort, A. M., and Vienna, the newly opened Stadtbahn in Vienna and the Wannseebahn in Berlin.

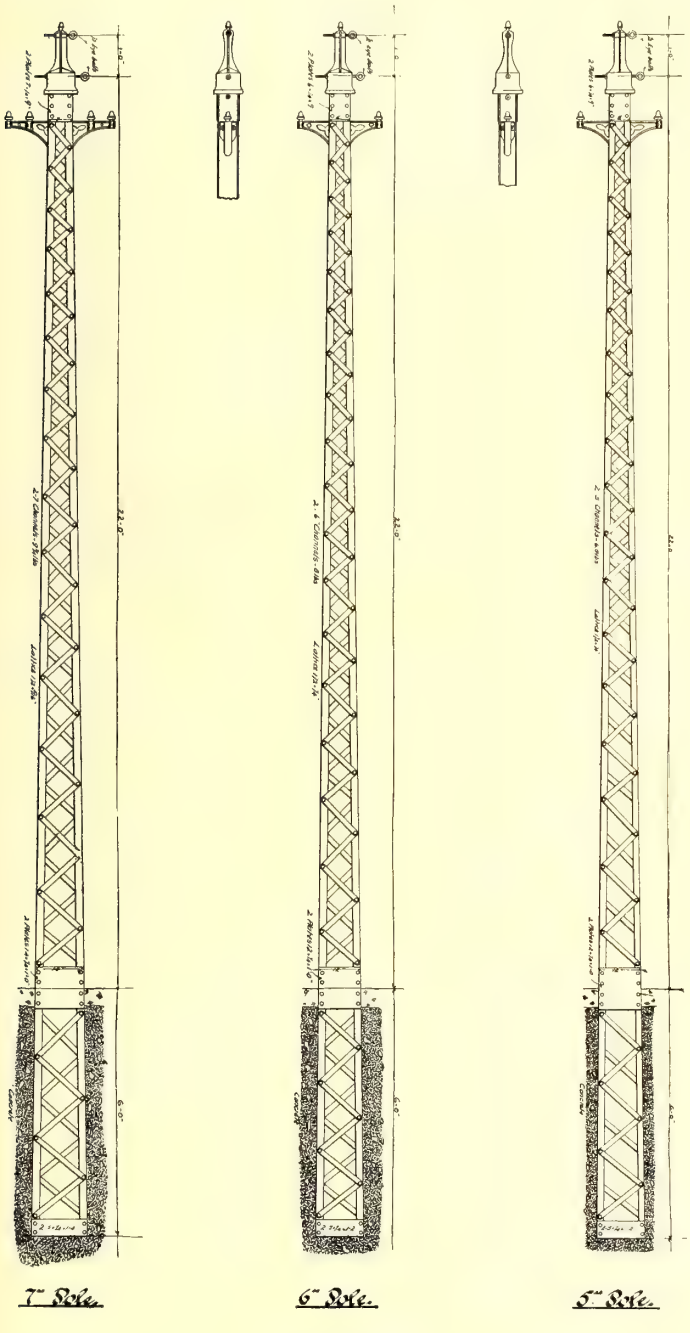
New Arc Electric Headlight

The accompanying engraving shows a new type of electric arc headlight, invented by H. Page Wellman, electrical engineer of the Ashland & Catlettsburg Street Railway Company, of Ashland, Ky., and in use on that line. The lamp is of the enclosed arc type, and is connected in series with about 500 ft. to 550 ft. of German silver resistance wire, No. 22, which reduces the voltage to that required by the lamp. The lamp is a hand-feed lamp, but has an automatic arc-starter, which automatically relights the lamp, after the current has been interrupted and again restored. The lamp will burn from two to three hours, when the carbons are easily fed together by the small knurled hand-wheel extending through the top. The carbons are so arranged that the arc is always in the exact focus of the parabolic reflector used.

It gives a very powerful light, which can be seen a half-mile

ARC ELECTRIC HEADLIGHT

away, and lights up the track so as to show clearly all objects in front of the car. The lamp consumes about 3 amps. of current, and is so arranged that it can be moved from one end of the car to the other. The connection is made by a plug located under the platform. The arc-enclosure is in the form of a transparent tube projected through the reflector, with the ends closed by caps, through which the carbon rods extend.



The arc-starting device has a cut-out, with a series coil, which controls the shunt magnets that operate to strike the arc, or, in other words, when the lamp is burning the armature of the cut-out is held suspended and open-circuits the shunt magnet coils, cutting the circuit out of them; but when the lamp is not burning this armature is down, and connects the shunt coils directly in the lamp circuit. Upon current being restored to the lamp it first circulates through the shunt magnet coils, and then through the series coil, cutting out the shunt coils and striking the arc.

Annual Oyster Roast

The sixth annual oyster roast given by the Berlin Iron Bridge Company, of East Berlin, Conn., to its employees was held on Wednesday evening, April 26, at East Berlin, and was a complete success in every way. These annual excursions are looked forward to with great eagerness by all the employees of the company and these dinners are considered largely responsible for the cordial good feeling existing between the managers of the company and the employees.

New Type of Lattice Pole

The accompanying engravings show a style of lattice pole which is manufactured by the Hilton Bridge Construction Company, of Albany, N. Y., and has met with considerable favor on some electric railways. The pole is designed primarily to give the greatest strength and stiffness possible, with an economical use of steel, and is made up with various sections of rolled steel channels, latticed with steel bars, in the manner familiar to every one in the present age of structural steel. By the use of larger sections, the pole may be made to stand the heaviest loads ever carried by line poles, and in all the various sizes of poles the strength is greater and the deflection less under the strains brought by the wires than in the case of much heavier poles made up of iron pipe. The experience of roads using the steel channel poles has been found to verify the calculations of engineers regarding the theoretical efficiency of latticed steel columns for such uses.

LATTICE POLES

The overhead construction, at best, is a source of discomfort to the portion of the public most interested in the æsthetic appearance of city streets, and anything which will improve its appearance is worthy of consideration. For this reason the form of pole illustrated is claimed to have a double bid for popularity—its actual lightness makes it cheap, and its apparent lightness makes it attractive to the eye. It requires no ornamentation except good paint.

The following table shows the principal characteristics of these poles:

TYPE OF POLE.	Weight.	Moment of Inertia.	Moment of Resistance, Unit Stress, C.	Safe Horizontal Pull.*
No. 1	550 lbs.	73.11	15.37 C.	698 lbs.
No. 2	650 lbs.	86.02	18.70 C.	850 lbs.
No. 3	800 lbs.	149.22	27.33 C.	1,242 lbs.

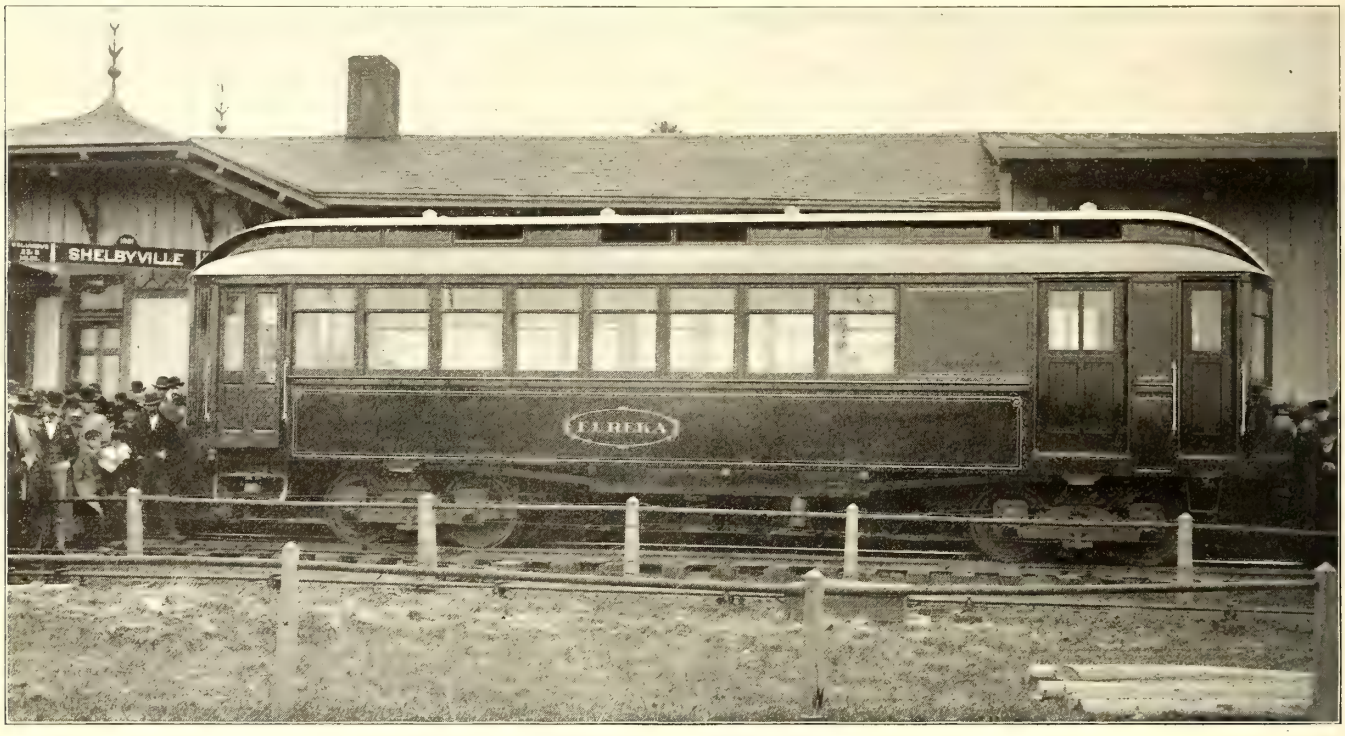
* Applied 22 ft. above ground, assuming maximum fibre stress of 12,000 lbs per sq. in

Hydro-Carbon Car

The gasoline or petroleum engine has been developed to a marked degree within the past ten years, and American ingenuity has produced engines which are reliable and economical. The advantages of this method of producing power are so numerous and well understood that they need not be mentioned here. Suffice it to say, that producing of power by the direct application of heat is the simplest way possible, as no transmitting medium, such as steam, is needed, the only thing necessary being combustible material and the oxygen of the air, which is free and found everywhere.

The practicability of gas engines for railroad use depends merely upon the proper arrangement of power-transmitting appliances, whereby the power from an engine can be applied to the axles so as to revolve them at any desired speed from zero to a predetermined maximum. This has been accomplished in the car illustrated herewith, which made its maiden run recently at Columbus, Ind., where it was inspected by a representative of the STREET RAILWAY JOURNAL.

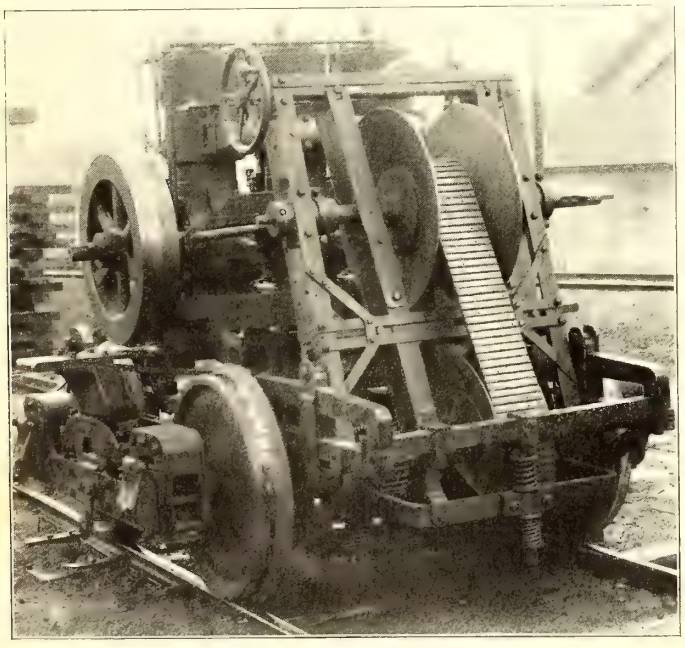
The car was built by the Vimotum Hydro-Carbon Company, of Chicago, weighs approximately 21 tons, is handled with a 45-h.p. three-cylinder, two-cycle gasoline engine, with the utmost ease and reliability, and starts, stops and reverses on short radius curves and grades without the slightest jar. It is mounted on a pair of standard M. C. B. trucks. The forward axles, besides carrying the regular truck, carry an inner frame, designed along the lines of a locomotive frame work. This frame has three points of suspension, and is provided with equalizing bars to provide for rock and tilt. Boxes are carried by the axles, which slide in ways, formed in this inner frame. Springs are interposed between the frame and axles, which give to the former a vertical resilience. This inner frame carries the engine, which is provided with a governor which regulates the speed to a predetermined number of r.p.m. A belt wheel, carried by the crank shaft, is belted to the initial shaft of the "Reeves" mechanism through a clutch carried thereby. This mechanism is supported on a supplemental frame yoked to the axle, and having the free end of the yoke suspended from the inner frame upon springs. This yoke keeps the axle gears, and mechanism gear, in mesh, but still allows a resilient movement of the mechanism relatively to the axle and to the inner frame. It will thus be seen that everything, from the engine to the axle gears, is resiliently mounted, but all maintain a given fixed relation to each other. All of this is independent of the car body, and the jar due to uneven roadbed, which is received by the inner frame, is absorbed thereby through its connections, and the same is not transmitted to the car body proper, the latter riding absolutely independent of the machinery.



In starting, it is merely necessary to throw a lever, which starts the engine, while the car remains stationary. When the signal is given to proceed, the clutch is thrown into the variable gear, the latter being in a position where its belt has its least lineal velocity. This starts the car easily and smoothly, and the speed is gradually increased to the maximum. To stop, the clutch is released, the mechanism returned to its slowest position, and the brakes set. These operations are accomplished simultaneously by the operator. The reverse is controlled by the engine lever.

Some particulars will now be given of the variable gear to which reference has already been made. This is the outcome of several years of experimenting, conducted by the Reeves Pulley Company, of Columbus, Ind., manufacturers of power transmitting appliances.

The mechanism primarily consists of two parallel shafts mounted in a suitable iron or steel frame. Each shaft carries a pair of driving pulleys, having the form of truncated cones, with their smaller bases facing each other, thus forming a V shaped groove between them. These pairs of pulleys are splined upon their shafts, and are capable of longitudinal movement thereon, but must rotate with their shafts. The corresponding members of each pair of pulleys bear, at their hubs, against ball thrust bearings, carried by levers,



which are pivoted between the shafts and extended at one end to engage with nuts carried by a right and left hand screw shaft which is adapted to oscillate them simultaneously, but in opposite directions. This oscillation causes one pair of pulleys to slide toward each other, and the other pair to slide apart at the same time. An endless belt, of unique construction, is stretched between

The object accomplished in this machine has long been sought for, but a number of seemingly unsurmountable mechanical difficulties presented themselves, which were not met and overcome until the present time. One of these was the belt requirement. It is necessary to have a continuous belt of a predetermined length, and in a machine of this class it was found that if both pair

HYDRO-CARBON CAR AT SHELBYVILLE, IND.

these pairs of pulleys and in the V shaped groove which has its driving surface on the edges thereof, instead of upon the "flat" as in ordinary belting practice. The specially constructed belt is very rigid in cross-section, but is flexible longitudinally, and will pass around a circumference smoothly and easily. It will be readily understood that as one pair of pulleys move together, the belt is caused to move outwardly thereon and assume a large driving diameter, while the other pair move apart and the belt moves down

VIEW OF DRIVING MECHANISM

in the V groove and assumes a comparatively small diameter. If one shaft is driven at an initial speed, the other shaft can be varied to any required degree above and below this initial, as the lineal velocity of the belt regulates the speed of the driven shaft, and this velocity depends upon the diameter upon which the belt is working on the pulleys carried by the initial shaft.

of pulleys were moved in the same ratio, different lengths of belt were required to connect the pulleys when they were in the different positions. This belt length is accurately found by use of the well-known formula.

$$\text{Length} = R(\pi + .0349a) + r(\pi - .0349a) + 2D \cos a$$

$R = \frac{1}{2}$ diameter of large pulley.

$r = \frac{1}{2}$ diameter of small pulley.

$D =$ length between centers.

$$a = \text{angle whose sine is } \frac{R - r}{D}$$

$$\cos a = \frac{\sqrt{D^2 - (R - r)^2}}{D}$$

$\pi = 3.1416$

By this formula it will readily be seen that this variation in belt requirement is considerable, much more belt being required to connect the large diameter of one pair of pulleys with the small diameter of the other pair, than is required to connect the pulleys when the belt is upon the same diameter of each pair, the mean between the large and small diameters. The Reeves Company succeeded in overcoming this by a specially constructed lever which imparts to the pulleys a differential sliding movement along their shafts, so that the proper diameters are presented to the belt to keep it under a uniform tension. The device is complete in itself, and is rapidly going into use in many lines of manufacture where a variation of speed is required. This adaptation of the mechanism to the propulsion of a car is a departure of note.

The machine in this car, complete, weighs 1000 lbs., and is capable of starting and accelerating the car on excessive grades. The mechanism is placed in an upright position so as to economize space, and this position has practically no effect upon the working of the belt, as its driving does not depend entirely upon adhesion, as in ordinary belts, but upon adhesion and due to the initial tension of the belt and the centrifugal force. In this connection, it might be mentioned that this tension due to centrifugal force is taken advantage of in exactly the right place. When the belt is upon the largest diameter of the initial pulley it has its greatest lineal travel, therefore the greatest centrifugal tension. This centrifugal tension aids in keeping the belt from slipping on the smaller diameter of the driven pulleys. As the speed is cut down, the lineal velocity of the belt is decreased, and the centrifugal tension is thereby reduced in proportion to this reduction.

The very best quality of material is used in its construction, and

the best workmanship possible is shown in its design. All parts are interchangeable and standard, and adjustments are provided. As the Reeves Company has had quite a number of these variable gears in hard practical use for four years, and as they are in as good condition to-day as when made, there seems to be no reason why they should not last as long as any other part of a car.

Parlor Car for New Brunswick, N. J.

The Brunswick Traction Company, of New Brunswick, N. J., has recently added to its rolling stock the handsome parlor car illustrated on this page. The main dimensions of this car, which

INTERIOR OF PARLOR CAR

is from the works of the Jackson & Sharp Company, of Wilmington, Del., are as follows: Length of body, 26 ft.; length over bumpers, 36 ft.; length of platforms, 4 ft. 6 ins.; width at sills, 7 ft. 3 ins.; height over belt rails, 7 ft. 9 ins.; height from sill to roof, 8 ft. 10 ins.; height from truck to sill, 2 ft. 6 ins.

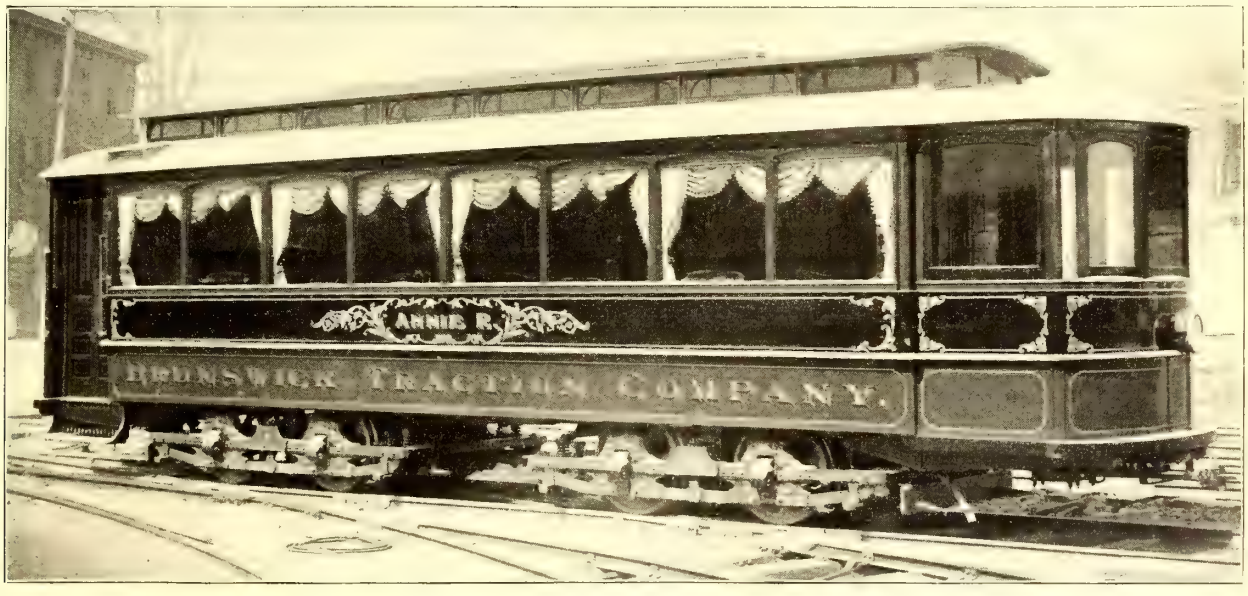
The body is constructed from the very latest pattern, is very wide over the frame, and has a shallow concave panel, thus giving plenty of floor space. The window openings are fitted with polished plate, fixed permanently. The roof is of the monitor type, with colonial deck sashes, fitted with fine Venetian glass with gold ornamentation.

The vestibules are of the usual type, except that one side is closed permanently, and the other side is fitted with double folding doors. The glass in all doors is beveled. The interior of the vestibules is finished in quartered oak, and on the side that is closed is placed a large refrigerator, one in each end. The floor is covered with rubber, and all the trimmings are nickel plated.

The interior of the car is finished in St. Jago mahogany, handsomely carved, and between the window sill and the floor it is paneled. In one end of the car are two buffets, with places for holding glasses, etc., and lockers beneath where supplies can be kept. The curtains are of silk tapestry, and fitted with Burrowes fixtures. The lambrequins are made in pairs and are of a handsome silk goods, draped in a neat manner. The carpet is Royal Wilton of a dark green color with a small figure. The ceilings are painted in two shades of green, are decorated in gold, and give a very handsome effect to the car.

All the chairs are mahogany, and are upholstered in silk plush and velour, all in dark green. Two small Chippendale tables are in the center of the car. All the trimmings inside are silver plated. The electroliers are placed so as to divide the light in the car to the best effect. Twenty lights are used in all, including electric headlight at each end. Push buttons are provided at each post. The end doors are of the usual double type, mounted on contra-twist fixtures made by the Adams & Westlake Company.

The trucks are of the Peckham 14 B short wheel base type, with 30-in. wheels, and by using these single steps are used, which is a great advantage. The car is equipped with Westinghouse No. 38 motors.



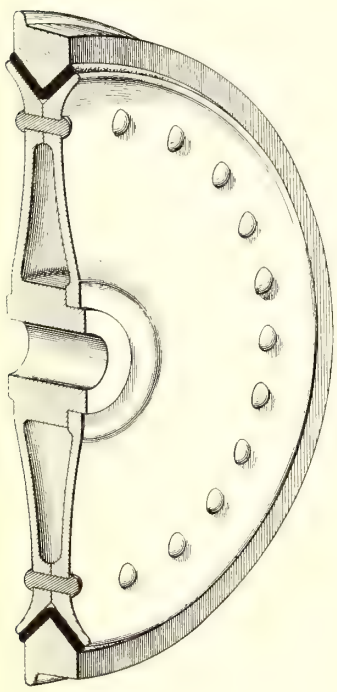
The Jackson & Sharp Company is also building a number of open cars for service on the lines of the Brunswick Traction Company, as well as a number for some of Mr. Radel's other railways.

Lubrication of Bearings

A lubricant adapted for use on locomotives, street cars, passenger coaches and machinery of all kinds, and for which is claimed extreme purity and economy, is manufactured by the Keystone Lubricating Company of Philadelphia. It is stated that the process of the manufacture of this grease is entirely different from that of making any other grease or oil on the market. The raw material is put through a chemical process known only to the manufacturers, and this process separates the foreign matter from the lubricant. The compound is then paddled by a process of direct natural heat until, it is claimed, it is perfectly pure. No gum, rosin, or other foreign constituent is put into the lubricant to give it body, as the process of manufacture leaves it with sufficient body without the addition of other substances.

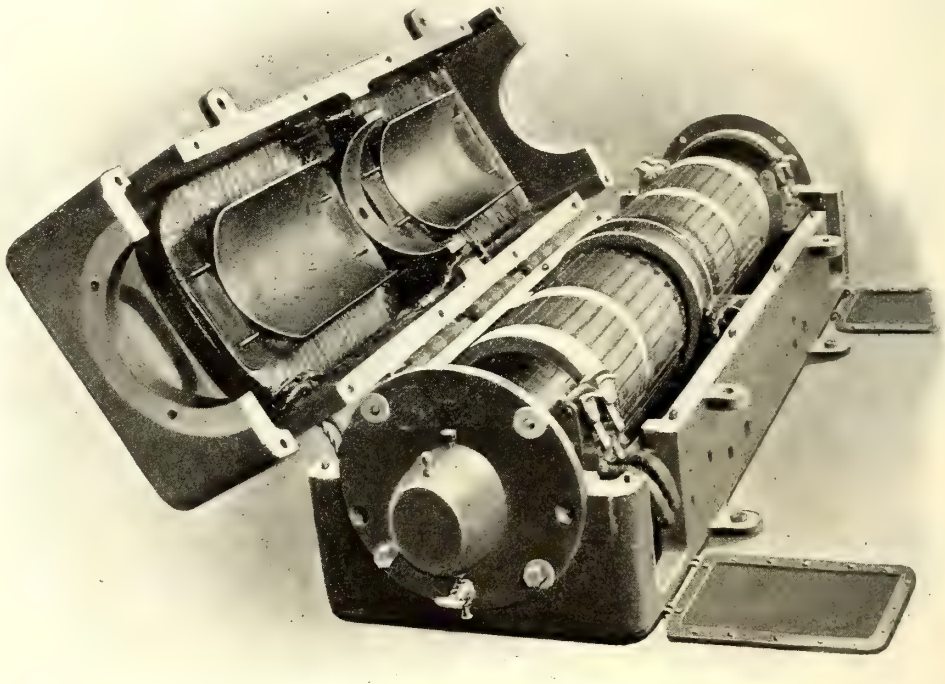
The manufacturers of the Keystone lubricants have paid special attention to the requirements of electric railways, and they claim that one application of their grease on the bearings of an electric railway motor will go four times further than any other compound. In perfecting their process the following points have been kept in view: To constantly moisten the bearings, to avoid evaporation but to secure perfect adhesion of the bearings, to avoid all foreign elements that might in any way unevenly wear or clog the bearings, and to preserve the bearings bright and clean.

The lubricant remains inactive when the bearings are at rest and works only when the machinery is moving, thus avoiding unnecessary waste.



PARLOR CAR FOR BRUNSWICK TRACTION COMPANY

Cushioned Car Wheel



A wheel to reduce the rattle of electric cars in operation is shown herewith. This wheel has an elastic cushion between the rim and body of the wheel, by which the vertical and lateral jar and vibration are absorbed and the noise insulated, and its construction is such that the end thrust is cushioned. It is particularly adapted to electric cars on account of the great weight attached directly to the axle which receives little benefit whatever from any springs on such cars as at present constructed. Electrical connection is made by a simple U shaped metal band inserted through the cushion and held in contact with the rim and body of the wheel.

The cushion is securely confined and has a large bearing surface against the rim and body of the wheel. The wheel is easily and firmly assembled

The first cost is more than for wheels now in common use, but to offset this is the advantage derived by being able to renew a worn out wheel by simply supplying a new rim, which is done without drawing the wheel from the axle. In substituting this for the ordinary wheel, street car companies are not obliged to throw aside any property or to make any changes in construction. The wheel has been thoroughly tested in practice. It was invented by C. H. Cameron, of Chicago, Ill., and he is now endeavoring to make arrangements for placing it on the market.

CUSHIONED CAR WHEEL

MOTOR GENERATOR FOR THIRD RAIL CARS

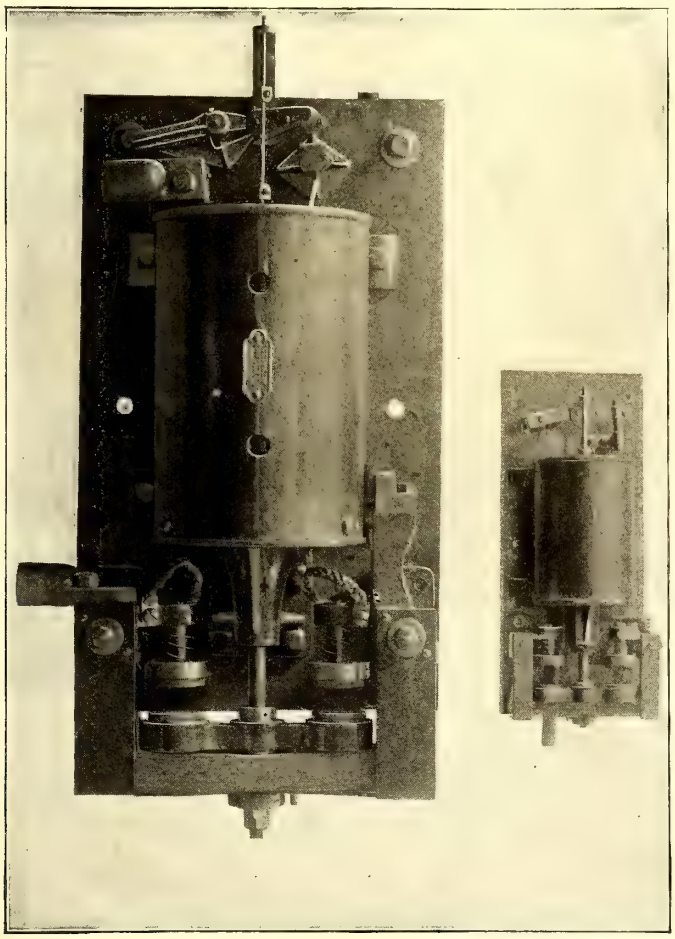
Public Test of Safety Third-Rail System

On April 12, the Murphy safety third-rail system installed at Manhattan Beach and fully described in the Street Railway Journal for April was subjected to severe tests in the presence of about 500 people. The automatic switches were, of course, the chief object of criticism of the electrical engineers. Their appearance is shown in the cut on page 327. They are of the solenoidal type and are provided with two bobbins. One is a fine wire, high voltage bobbin, and the other is of coarse wire and carries the main current which feeds the section. The operation is as follows: Suppose that the car is in motion and taking current from one of the sections, as described last month. The forward collecting shoe impinges on the section and current flows through the fine wire winding to ground. This raises the plunger, closing the coarse wire circuit and breaking the fine wire circuit. The series current keeps the switch closed as long as the car is taking current from that section. When current ceases in this circuit, and not till then, the switch releases its plunger, and as there is no current to break there is no arc at the switch jaws and thereby a serious disadvantage common to many systems of this class is eliminated. This was efficiently demonstrated at the test. A large box of switches were grouped together for observation, and as the car passed over the various sections of track which they controlled, the switches operated without arcs of any kind, though they were handling currents of from 20 amps. to 60 amps., as shown by the station ammeter.

The switches are subjected to a most severe test before being put into service, being required to make and break circuit with great rapidity for a period exceeding at least twenty-four hours, thereby making a number of breaks equivalent to many thousands of miles of service. The copper laminated jaws of the switches are supplemented with carbon jaws which are arranged to be the last to break circuit, thus providing for arcs in case of accident of any kind.

If the car is stopped all of the switches will fall, thereby cutting the current off from the power house, and means are provided to pick the switches up again. This consists, as mentioned last month, of a storage battery and a little motor dynamo. A storage battery of ten cells drives this motor dynamo which lights the car and provides 500-volt current to pick up the switches. The car lights are therefore never out, which is a great advantage. As the lamps are run directly from the storage battery they are on the multiple plan, which avoids the inconvenient arrangement of five lights or more. Moreover, the lamps being of low voltage with short, stumpy filaments, are of very long life, and being supplied by the storage battery are of uniform brilliancy whatever the line voltage may be.

The car once started the sides of the rotary transformer exchange functions. It takes current from the line and charges the storage battery which, therefore, does not require to be removed and charged, and, in short, does away with all additional attention.



The motor dynamo is an interesting little machine and is shown on this page. It is entirely iron clad and is built on the rugged lines of a railway motor. It has two ratios of transformation This is necessitated by the fact that the storage battery requires to be charged at about 25 volts and discharges at full load at about 20 volts. Therefore the rotary transformer must charge at the rate of from 500 to 25 and discharge at the rate of 500 to 20. This performance is obtained by adding to the windings of the machine a 500-volt field coil which is connected, not to the terminals of the rotary converter, but to the trolley and ground. Hence, when the power house current is absent, the motor dynamo receives the excitation from the low potential side and gives the greater ratio of transformation. When the power house current is at hand, the high voltage coil produces the proper changes in magnetization to alter the ratio of transformation as required.

Another interesting exhibit at the Beach consisted of a large switch for handling heavy locomotive work. This switch is shown on the opposite page, photographed beside a switch for ordinary street railway work. The switch weighs nearly 400 lbs. and has

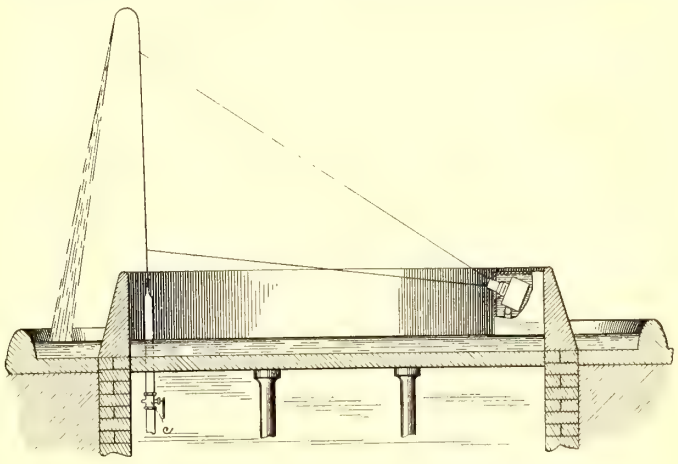
very powerful and massive jaws, which carry the necessary currents for handling 80-ton and 90-ton locomotives. These jaws are reinforced by carbon contacts which will take any arcing which may occur there. These arcs, however, as a matter of fact, are slight because of the series coil device.

The cost of this system has given rise to a great deal of speculation, and as the Safety Third-Rail Electric Company has not yet gotten its equipments on a manufacturing basis, definite figures cannot be given, but it is believed that the cost of this system will not exceed that of an equivalent first-class overhead system.

The only serious item of depreciation in the system is the switches, and as these consist of about one-third of the total investment for outside electric construction, they can suffer a very large depreciation without bringing the total depreciation figures to any serious magnitude. In fact, the company proposes to guarantee the depreciation of this item for 10 per cent of the first cost of the switches or about 3 per cent of the total investment. When it is remembered that outside construction on the overhead system is frequently written at 15 per cent, this figure becomes very pertinent.

STANDARD SWITCH AND SWITCH FOR HEAVY SERVICE

During the exhibition at Manhattan Beach an elaborate luncheon was served and congratulatory speech-making followed. A large representative body of railway men was in attendance.



An Ornamental Fountain

After years of experimental work, Paul C. Just, who is in the employ of the North Chicago Street Railway Company, has succeeded in perfecting an improvement for electric fountains, and he has been granted United States patents covering the same.

The invention consists in the combination of a nozzle or other means for throwing a flat jet or sheet of water into the air, and a picture projecting apparatus, such as stereopticons or kinetoscopes so located with reference to said flat jet or sheet of water as to throw a picture or image upon said sheet.

The illustration published herewith shows the invention as it was exhibited at the electric fountain at Lincoln Park, Chicago, in 1898, where it proved a very great success, and one of the most striking and popular exhibitions ever given. It greatly increased the number of people visiting the park on the evenings when the fountain was in operation and the hearty applause of the crowds in nightly attendance evinced the appreciation of the beautiful display.

An electric fountain is not necessary for a display, a single supply pipe from a tank with from 50 lbs. to 65 lbs. pressure fully answering the purpose. A nozzle placed in a pond or lake with the projecting apparatus located conveniently, gives a beautiful effect.

SECTIONAL SIDE VIEW OF FOUNTAIN

The image appears to be suspended or floating in the air. The upward movement of the water is not visible in itself. One remarkable feature about this invention is the extreme distinctness or definition of the image and the fact that the same may be seen as well from the side of the jet or sheet remote from the projecting apparatus as from the side adjacent thereto.

Large Supply House

The Electric Appliance Company, of Chicago, has recently removed into its new building at Nos. 32 to 34 West Van Buren Street, where it will carry a much larger stock of all kinds of electrical supplies than ever before. The interior construction of the new building was especially arranged for the company and is a model of convenience and adaptability. It contains five stories and a basement. On the ground floor are the general offices of the company, to the left that of W. W. Lowe, president of the company, and to the right and opposite that of T. I. Stacey, secretary and treasurer. To the right of the latter are the general offices, and to the left of the general offices is the storeroom. Occupying the rest of the first floor is a room devoted to outgoing and incoming freight.

On the second floor the manager of the shipping department has his office, his assistants' desks and benches for assembling use about half the space of this floor, the rest being devoted to bins for shades and shade holders, sockets, switches and miscellaneous stock. The third, fourth and fifth floors, with the exception of the list of goods stored in them, might well be described in the same paragraph; they are arranged with bins, racks and shelves to best suit the stock carried in them. The telephone department and shop are also located on the third floor as well as the offices of S. A. Dinsmore, the manager of this department.

The last, but by no means the least important part, is the basement, with its accommodations for heavy goods—Armorite and Armorduct tubing, "O.K." bare copper and iron wire, cross arms, brackets, polesteps, etc., etc.

On each floor is a stock clerk, who must be thoroughly posted on the stock under his immediate control. All bins and shelves are lettered or numbered, classified and indexed in such a manner that the assembler can at once place his hands on the item wanted. Every arrangement or device which would in any way help toward the desired end—a quick shipment—has been employed.

The history of the house which has grown in a few years to so prominent a position is briefly as follows:

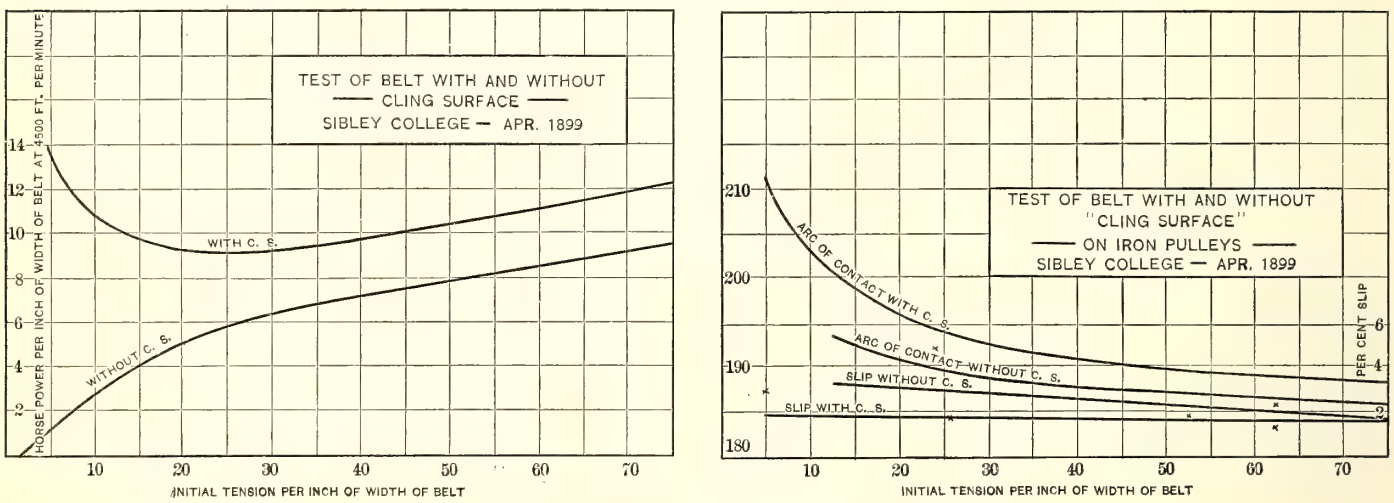
The company started in business Dec. 1, 1891, using one floor of the building at 242 Madison Street, Chicago, with 2500 sq. ft. of space. One year later another floor was added. In the latter part of 1894 the entire building, or 8000 sq. ft., was required. The present location, at 92 and 94 West Van Buren Street, has 30,000 sq. ft. of floor space. So much in the way of history. With the increased facilities for quickly handling goods, which the new building affords, and with the additions to the strong list of agencies which the company represents, the management may confidently look forward to another prosperous period. The prompt

and businesslike policy which has pleased and multiplied this concern's customers during the past eight years will hardly fail to bring like results in the future business.

Compound to Prevent Slipping of Belts

The Cling-Surface Manufacturing Company of New York city is introducing a compound for rendering power belts soft and pliable, and for increasing the efficiency of a power plant by reducing the slipping of the belts. A very thorough test of this compound was made recently by R. C. Carpenter, professor of experimental engineering at Sibley College, Cornell University, Ithaca, N. Y., and the following is his report upon the results:

The tests were made in every case on the belt testing machine owned by Sibley College; this is constructed so that the belt can be tested under ordinary running conditions and measurements can be made for determining the power supplied, the power delivered, the tension of the belt, the arc of contact on either pulley, and the slip. Three belts have been tested, each before and after treating with cling-surface, and each under various conditions of loading. In all over fifty tests have been made; a considerable number of observations have been repeated in order to check the accuracy of the results.



The belts before testing were in every case clean and in good condition, and running under rather better than average conditions.

The cling-surface was applied on several successive days, and in small quantities, in accordance with the directions supplied by the manufacturers, before commencing the tests. The material was almost wholly absorbed at the time of starting the test, and none has since been applied. The material made the belt soft and pliable, and gave it an inner surface somewhat resembling patent leather. This surface was only in the least degree sticky to the touch.

The general results of the test with cling-surface show an increased transmitting power as compared with the same belt in an untreated condition; it also shows an increased arc of contact, and very much less slip. It shows a very high transmitting power when the belt is run extremely loose, or with very little tension on the pulleys, the reverse of which is true with the untreated belt. It will be seen by consulting the report that the greatest transmission capacity for the belt treated with cling-surface was found when there was the least possible tension on the belt, and when the belt was running so slack that the sides nearly touched. It will be noted also that as the tension of the belt was increased the transmitting capacity diminished until a tension of about 20 lbs. per in. of width of belt was reached, after which the transmitting capacity commenced to increase, and from that point continued to increase with increase of tension.

In the test of the same belt not treated with cling-surface the results were quite different, inasmuch as the capacity with very light tensions was practically nothing, and the capacity increased as the tension increased; at no point, however, did the untreated belt have even approximately the same capacity as the treated belt with the same tension; moreover, the treated belt transmitted much more power with a very light tension than the untreated belt with a heavy tension. The test with the belts treated and untreated, running on wooden pulleys, showed essentially the same characteristics. The general effect of the cling-surface appears to enable the belt to transmit a power equal to its entire capacity without producing heavy stresses on the driving boxes of the pulleys; or, in other words, it enables the full capacity of the belt to be obtained for transmitting power when the belt is so loose that the sides nearly touch.

The general results of the tests of the untreated and treated belts when running on iron pulleys is shown in the accompanying diagrams, Figs. 1 and 2. In Fig. 1 the horizontal distances show the tension on the belt in lbs. per in. of width, the vertical distances show the h.p. transmitted per in. of width of belt for a speed of 4500 ft. per minute. The lower line represents the results obtained with the untreated belt; the upper line the results obtained with the treated belt. It will be noted that the lower line continually rises, showing an increase in capacity with an increase of tension; the upper line descends at first, showing a decrease in capacity with increase of tension, and later rises. In no place does the transmitting capacity of the treated belt fall below that of the untreated belt. In comparing the respective results it will be noted that the treated belt has a carrying capacity of 13.8 h.p. when the tension per in. of width is 5 lbs, while for the same conditions the untreated belt has no carrying capacity; furthermore, it is noted that the carrying capacity of the treated belt, even at this low tension, is nearly 40 per cent higher than that of the untreated belt, even when the tension has been increased to 80 lbs. per inch of width of belt. The diagrams in Fig. 2 show the arc of contact and the maximum percentage of slip for belts run both in the treated and untreated condition with different tensions and on iron pulleys. From this it is seen that the slip of a treated belt

DIAGRAMS SHOWING RESULTS OF TESTS

The falling off in carrying capacity with increase of belt tension for the treated belt is doubtless due to the rapid change in the arc of contact, which diminishes with increase of tension. This causes a diminution in the transmitting power which is greater than that produced by the increase of pressure due to the increased tension on the belt. With the untreated belt such change is very slight, and consequently a falling off in carrying capacity for light tension takes place.

In regard to the questions raised as to the preservative qualities of cling-surface and to the permanency of the effect produced by its application, the writer would say that our tests have of necessity been of too short duration to give conclusive answers. The general effect of the cling-surface is to soften the belt and to put it apparently in the best condition for transmitting power and retaining its good qualities. The surface produced by the cling-surface remains apparently unchanged after several weeks of use, and the inference to be drawn is that the material has an effect which continues permanent for some time at least.

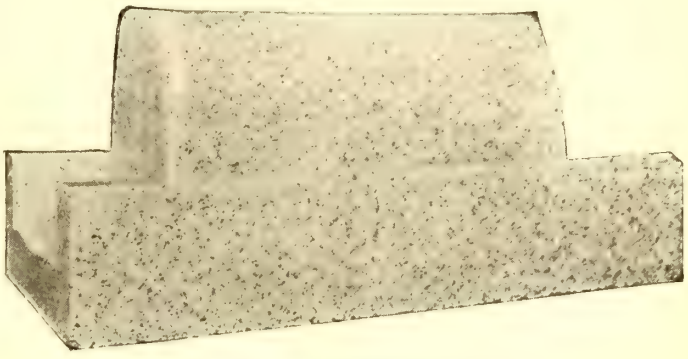
The Gothenburg (Sweden) County Council on April 4 decided by a vote of 32 to 14 to buy the local tramway's concession and properties for £70,000; this sale is subject to approval of the shareholders. The tramway company had its head office in London, and was started by English capital under a forty-year concession running from 1879. The following are the chief characteristics of the road: Capital stock, £50,000; 6 per cent debentures, £4300; reserve fund, £2800; dividend, 5½ per cent; number of horses, 132; rolling stock, thirty-six cars and four busses; mileage in operation, 6¾ miles.

Railroad Air Brake Men's Association

The sixth annual meeting of the Railroad Air Brake Men's Association was held in Detroit, Mich., on April 11, 12, and 13, the headquarters being at Hotel Cadillac. This is an international organization of 400 members, composed of men in Mexico, Canada and the United States, who are occupied with the care, operation or maintenance of air brakes. The Grand Trunk, Michigan Central, Wabash, and the Lake Shore Railroads each placed an inspection car, completely fitted with air brake apparatus, in the Union Depot yard for exhibition.

At the opening session on April 11, addresses were made by Mayor Maybury and Robert Miller, the veteran Michigan superintendent of motive power, and the President's annual message was received.

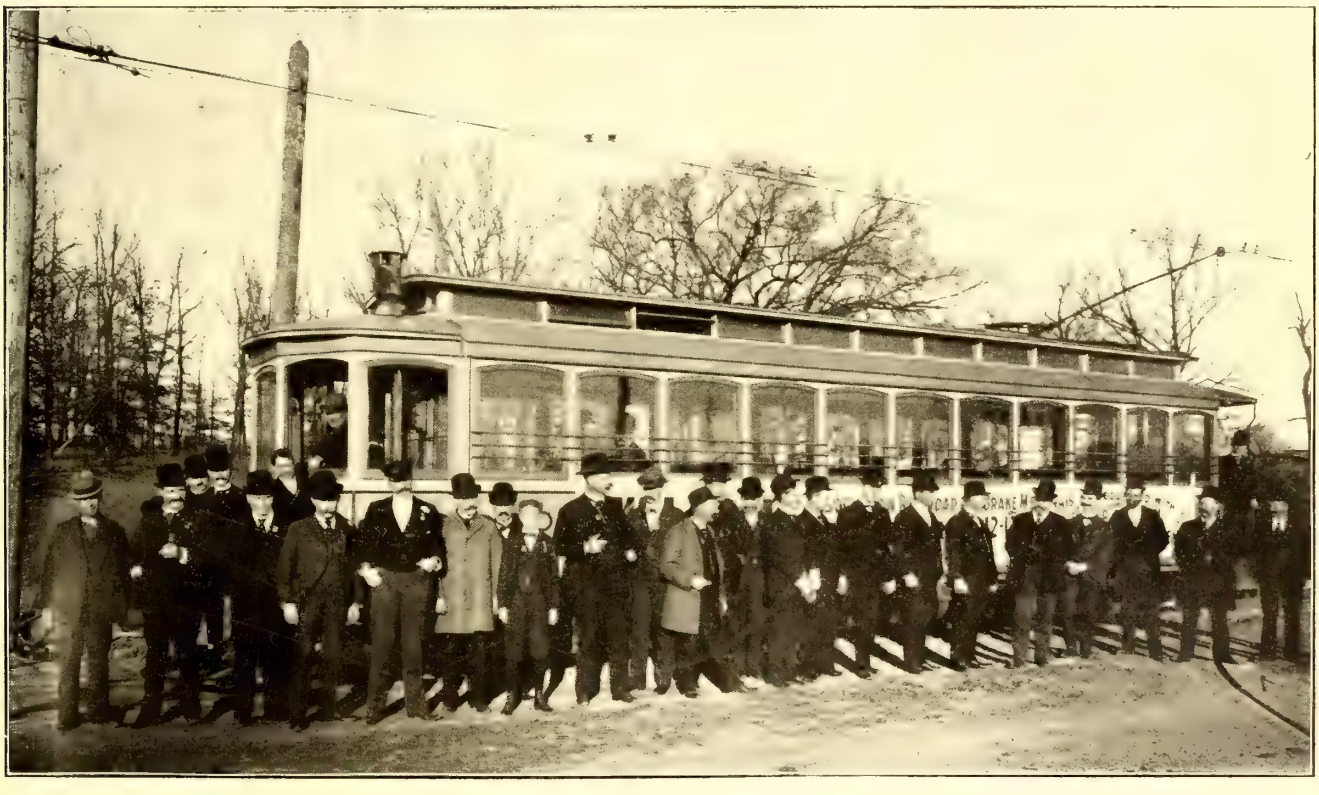
One of the most pleasant incidents of the meeting was the trip over the lines of the Detroit & Pontiac Railway, arranged by William D. Ray, of the G. P. Magann Air Brake Company, of Detroit. The trip was made in a special car, equipped with the Magann storage air brake system, and a number of tests of the brakes were made on the trip.



The party, consisting of over fifty delegates, started in the afternoon of April 12, made the 17-mile trip to the Birmingham power house in remarkably short time, and the true Detroit hospitality was shown on this occasion in many ways, and the air brake men enjoyed themselves thoroughly. After leaving the city limits, the car was run at very high speed. While going at the rate of 47 miles an hour an emergency stop was made with the air brakes, and the car was brought to a standstill within a few feet. Numerous service stops were also made, and it was noticed that each stop only caused a reduction of .6 of a lb. of air, showing what efficiency the storage air brake system has reached. At Birmingham the car was run over a pit, where the apparatus was inspected and air applications made.

A special test was conducted on March 15, when car No. 5 left the power house at Birmingham for Detroit with 230 lbs. of air. The car made two round trips, consuming 160 lbs. of air and making a total of 300 stops. The time consumed was six hours. The car made a total mileage of 104 miles. After completing the two round trips there was still 70 lbs. pressure. The car was equipped with double action cylinders.

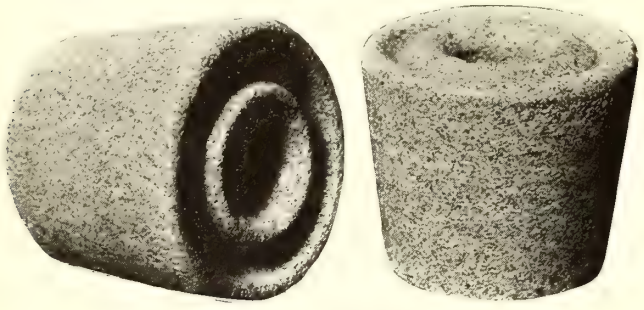
It will be seen from these results that there was only about 8-15 of a lb. of air used for each stop. On March 16 a car made 165 stops, consuming 88 lbs. of air.



Reconstructed Granite

In the April issue of the STREET RAILWAY JOURNAL some particulars were given of the third-rail railway at Coney Island. One of the important features of this line is the insulating blocks made of reconstructed granite, used between the rail sections. This material is so novel, and possesses so many remarkable properties, that it is thought that a description of it would prove of interest.

THIRD-RAIL SECTION BLOCK



"Reconstructed Granite" is exactly what its name implies, and consists of choice Maine granite, pulverized, moulded into form and fused together at a temperature of 3000 deg. F. It differs from the natural stone, of which it is composed, in several very important respects, viz: (1.) In being absolutely fireproof, as it can be heated red-hot and thrown into cold water without being in the slightest degree injured or affected thereby. (2.) It resists the action of every known solvent, acids and alkalies of all kinds, except hydro-fluoric acid, and is only superficially affected by that. (3.) It is absolutely frost-proof, having been tested in liquefied air at an estimated temperature of 350 deg. below zero not only without injury, but was as strong while frozen as before, and not at all brittle, in this respect differing from all other materials tested in this way. As it is a well-known fact that all natural rocks are disintegrated by extreme cold, and as 80 deg. to 90 deg. below zero is the coldest temperature known upon earth, the test is a severe one. (4.) Natural granite not only contains a considerable percentage of moisture, but has a constant tendency to absorb

GROUP OF MEMBERS OF AIR BRAKE ASSOCIATION

more when exposed to dampness, whereas this material contains no moisture whatever, and being vitrified clear through (when prepared for electrical insulation), cannot absorb any. (5.) Its crushing strength, as shown by tests by the United States Government at the Watertown Arsenal, ranged as high as 14,560 lbs. per cubic inch, which is far above the average strength of the natural stone. Its tensile strength is from 480 to 500 lbs. per sq. inch.

Its great strength, its uniformity throughout, its non-absorbent properties, and its susceptibility to being rapidly and economically moulded into all ordinary shapes, at a comparatively low cost, would seem to make it a valuable insulating material, especially for railway work, when it would be constantly exposed to the

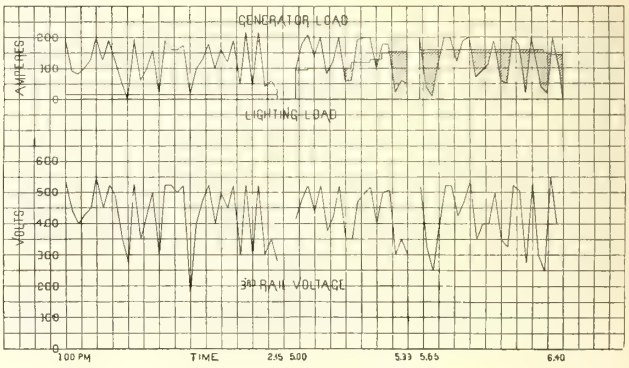
CUP INSULATORS OF RECONSTRUCTED GRANITE

weather, and frequently buried under ground, for these reasons it is rapidly growing in favor upon electric railways, especially for third-rail insulation. Herewith are shown two forms of these insulating blocks made of this material, the first being the section insulator of the "Murphy system" tested at Manhattan Beach, and the other the cup insulators of what is known as the "Martin system," now being introduced upon the Brooklyn and other elevated railroads. There are also many other forms.

A recent test at Niagara Falls showed that it required 56,600 volts to penetrate about ½-in. of this material with a merely nominal absorption after soaking the fragments for many hours. Many other tests equally satisfactory have been made by eminent electricians.

Reconstructed granite is manufactured at Norristown, Pa., by the Reconstructed Granite Company, of New York. These works are very extensive, covering nearly 7 acres of ground, and have direct connection to all parts of the country by both the Pennsylvania Railroad and the Philadelphia & Reading (B. & O.) Railroad, both of which have sidings into the works.

Storage Battery Auxiliary of the New York, New Haven, & Hartford Railroad



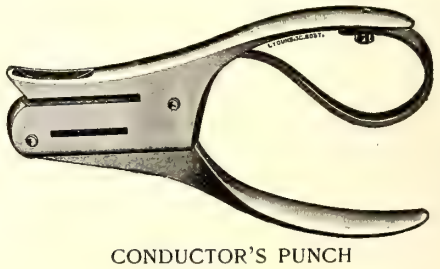
A little over a year ago the New York, New Haven & Hartford Railroad Company installed a plant with storage battery auxiliary at Hartford, Conn., for the purpose of lighting the Hartford station, that has been operating successfully ever since and which exemplifies in an unusual manner the advantage of a storage battery as a regulator, and its adaptability to unusual conditions. It will be remembered that the New York, New Haven & Hartford Railroad operates the Hartford-New Britain section of its line electrically by the third-rail system. Five hundred volts are used and the voltage is subject to all the fluctuations incident to such a system, on account of the current required for starting and accelerating the trains. The fluctuations on the circuit are more violent at Hartford as it is located at the end of the third-rail system, and were so great that lamps could not be operated from an ordinary motor-driven generator without battery. A combination of the motor-driven generator and regulating battery was, therefore, finally decided upon.

The generating unit consists of a 45 kw. shunt-wound generator direct connected on a common bed-plate to a specially compound wound 500-volt motor, the compounding being so designed as to run the motor as nearly as possible at a constant speed through large variations of voltage in the motor circuit, which is derived from the third-rail system of the railroad.

The scheme of operation and the results obtained are well exemplified in the curves shown in the diagram herewith. The lower curve gives an excellent idea of the extreme variations in the motor circuit. It will be noticed that this covers a range of 375 volts, or from a minimum of 175 volts to a maximum of 550 volts. The battery is directly across the system as a regulator, receiving its charge through the hours of light load as will be seen by reference to the left-hand set of curves in the cut, and only being required to furnish a small amount of current when the generator current drops off, due to fall in the voltage on motor, to a point below the lighting load shown by the straight line across the curve; but as the lighting load increases, it will be noticed from the right-hand set of curves in the same figure, there is a large portion of the time when the generator is unable to furnish the current required for the lighting load and which is in turn supplied by the battery, which thus keeps a practically constant pressure on the lamp circuits, discharging whenever the generator current falls below the load and charging when the reverse occurs.

In addition to this service, when the lighting load falls off to a minimum the generator is shut down and the battery furnishes all the current required at such time, constant potential being maintained by the ordinary method of cutting in reserve cells by switches on the lower panel of the switchboard.

The storage battery consists of sixty-two cells of Chloride Accu-



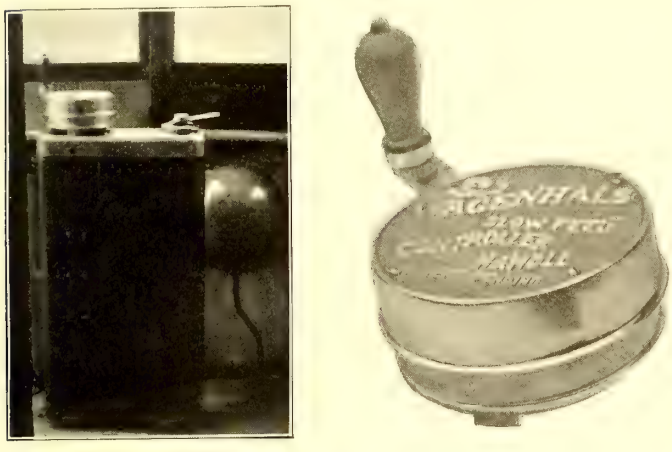
LOAD LINE—HARTFORD BATTERY

mulator, manufactured and installed by the Electric Storage Battery Company, of Philadelphia. Each cell contains eleven plates, but the tanks are large enought to provide space for additional plates to double the capacity of the present plant. The plates are of type "G," 15½ ins. x 15½ ins., while the containing tanks are 23⅜ ins. x 19¾ ins. x 22⅞ ins. high. The cells are installed in one tier on special porcelain insulators, the plates being burned up to solid lead busbars in accordance with the standard practice.

Conductors' Punches

The R. Woodman Manufacturing & Supply Company, of Boston, Mass., is one of the largest and oldest manufacturers of small steam and street railroad supplies, such as ticket punches, ribbon, office and perforating stamps, railroad baggage checks, coat and time checks, employees' hat and breast badges, uniform buttons of every description, etc., and is constantly bringing out new specialties.

One of its latest devices for street railway use is a transfer ticket



CONDUCTOR'S PUNCH

punch fitted with a new elliptical spring, which, it is thought, will be found a great improvement over the old types of springs. These punches are milled out over the top of the die so that conductors can very readily see all dates and figures which are to be punched in the tickets. The cutting dies for the punches are made from the very best Jessop's tool steel and this accounts for their lasting qualities and durability. Over four thousand of these punches are now in use on the street railways of Boston and vicinity, and the company has large orders on file from a number of roads in Canada.

The Corporation of Glasgow will shortly begin work looking to the conversion of their entire system, and they hope by the date of the Glasgow Exhibition in 1901, which will immediately follow the Paris Exposition, a considerable portion of the system may be converted to electricity.

A Slow Feed Controller Handle

In the accompanying illustrations is shown a new controller handle which has been devised by a practical electric railroad manager and which is believed to be one of the best checks ever devised for preventing the waste of energy by careless or indifferent motormen. There is, of course, no question as to the enormous amount of current that is absolutely wasted by green motormen by the improper handling of the controller. In addition to this direct loss, the increased cost of repairs to motor and parts damaged by excessive currents is by no means a small item. To

SLOW FEED CONTROLLER HANDLE

compel the motorman to use his power economically is the aim of the new invention.

The standard series parallel controller has nine points and the average motorman will cover these in six seconds with a consumption of 250 amps. with two 35-h.p. motors. With the new slow feed handle the time in which the motorman shall cover the nine points is under the control of the manager, who, by regulating an attachment on the controller can limit the time to eight, ten or twenty seconds, as he may desire. No alterations in the present type of controller are necessary to adopt the use of the handle, the old handle simply being lifted from the stud and the new handle put in its place. The device is manufactured by the Wagenhals Manufacturing Company, of Cincinnati, Ohio.

Lubrication of Gearing

The lubrication of the teeth of gearing is a subject of much greater importance and requires closer attention than is often given it, and too often waste lubricants from the bearings, engines, and machinery generally, are considered good enough to supply the gear teeth. The conditions under which gear teeth operate are so very much different from those of a revolving bearing that it is not proper to assume that the same lubricant will do for both; in fact, after careful experiments it has been found that by the application of a lubricant made especially for the purpose, the life of gear teeth can be very perceptibly prolonged.

Gear teeth should be constructed to have as little side clearance as possible and the perfect working gear would be one absolutely without side clearance. As a matter of fact, it is nearly impossible to so adjust gearing as to prevent all initial side clearance. This clearance soon gives rise to a hammer blow, commonly termed "back lash," thus tending to crystallization and breakage. As soon as this "back lash" has once started it very soon increases and the destruction of the metal is very much more rapid. It is evident that a lubricant to satisfactorily answer the varying requirements of gear teeth must possess tenacious qualities to adhere and be able to deposit on the working surface of the teeth, preventing metallic contact and consequent wear and noise and reducing side clearance, thus forming a cushion for "back lash." This is the exact opposite of the requirements of a lubricant for revolving journal bearings. A lubricant for accomplishing this result of a "gear shield" is made by the Ironsides Company, of Columbus, Ohio. This material has been used for some time and it is stated has greatly prolonged the life and decreased the noise of gearing on which it has been used. It is adapted to all conditions from the even running motor gearing on street cars to the most ponderous and heavily loaded gearing of rolling mills.

Annual Report of the General Electric Company

The following is an abstract of the seventh annual report of the General Electric Company:

PRESIDENT'S REPORT.

SCHENECTADY, N. Y., April 26, 1899.

To the Stockholders of the General Electric Company:

The prosperity which has attended other lines of business during the past year has been shared by your company. The important extensions made to its factory plants during the past eighteen months have proved to be most timely, and the company is now greatly benefited by the increased facilities they afford.

The matters of stock reduction and revaluation of the patent account of the company were brought to your attention in the last annual report. Since then a reduction has been made of 40 per cent in the share capital of the company, by vote of the stockholders at a meeting specially called for that purpose, the common stock being reduced from $30,460,000 to $18,276,000, and the preferred stock from $4,252,000 to $2,551,200. The patent account has been reduced from $8,000,000 to $4,000,000.

The profits for the year, after deducting all general patent and miscellaneous expenses, were	$3,896,884.10	
Deduct deficit as of Aug. 18, 1898, after reducing patent account and capital stock	1,840,761.03	
		$2,056,123.07
Less interest on debentures and current dividend on preferred stock		371,638.40
		$1,684,484.67
On Jan. 31, there had been paid or charged against surplus all the old accrued dividends on preferred stock		1,527,913.68
Surplus, Jan. 31, 1899		$156,570.99

By order of the Board of Directors,
C. A. COFFIN,
President.

FIRST VICE-PRESIDENT'S REPORT.

SCHENECTADY, N. Y., April 25, 1899.

C. A. Coffin, Esq., President General Electric Company:

Sir—I submit herewith a brief report of the operations of the Sales Department for the fiscal year ending Jan. 31, 1899.

Total sales (amount billed to customers)	$15,679,430.86
Cost of goods sold, general expenses and taxes, including sundry losses and allowances for losses	13,094,534.25
Profit on sales	$2,584,896.61

ORDERS RECEIVED.—The increase over last year in orders received is 21 per cent. Apparatus orders represent 52 per cent of this increase, supply orders 39 per cent, incandescent lamp orders 9 per cent. The increase in each class is:

Apparatus orders	19 per cent over last year.
Supply orders	24 " " " " "
Incandescent lamp orders	23 " " " " "

Over 124,000 separate supply orders were received and over 8,400,000 incandescent lamps were ordered, during the year.

About 89 per cent of the year's orders were on our standard terms—cash within sixty days.

Orders Received for the Past Five Years.

Fiscal year ending Jan. 31, 1895	$12,160,119
" " " " " 1896	13,235,016
" " " " " 1897	11,170,319
" " " " " 1898	14,382,342
" " " " " 1899	17,431,327

The local office stocks are maintained in good salable condition. The annual inventory shows these stocks classified as follows:

Active	92.5%	$442,380.43
Inactive	6.5%	30,666.60
Obsolete	1.0%	4,976.01
Totals	100.0%	$478,023.04

The improvement in this respect is shown by the following comparisons:

Local Office Stocks for Past Five Years.

	1895.	1896.	1897.	1898.	1899.
Active	68%	82%	86%	90%	92.5%
Inactive	27%	14%	12%	8%	6.5%
Obsolete	5%	4%	2%	2%	1.0%

GENERAL REMARKS.—The past year shows the largest volume of business for the company for any fiscal year since its organization. The increase is well distributed, as shown above.

During the past year large power houses have been constructed or projected in or near many of our large cities, which power plants are centers of distribution of the electric current for railway, lighting and many other and constantly increasing uses and applications. The establishment of such large stations will result in decreased cost and increased use of electric power.

The utilization of water powers by electrical transmission has also been a marked feature of the past year, and the successful transmission of electrical power over the 80-mile line of the Southern California Power Company, at Los Angeles, Cal., is the long-distance record to date of commercial transmission.

Some of the more important water power transmission plants which have been sold by this company are given in the following table:

Total H.P.	Power used at	Transmission Distance in Miles.	Voltage.
1670 H.P.	Redlands, Cal	21	10,000
3000 "	Portland, Ore	14.5	6,000
4000 "	Sacramento, Cal	22.5	11,000
2000 "	Pachuca, Mexico	19	10,000
1407 "	Fresno, Cal	55	19,000
2667 "	Salt Lake City	14	10,000
1206 "	Bakersfield, Cal	16	10,000
5000 "	Ogden & Salt Lake City	40	15,000
800 "	Hookset, N. H	10	10,000
1440 "	Cordova, Argentine Republic	16	10,000
1000 "	Varese, Italy	14	5,000
4000 "	Los Angeles, Cal	80	33,000
2000 "	Provo, Utah	40	40,000
5000 "	Schenectady, N. Y	19	12,000
4000 "	Butte, Montana	21	15,000
235 "	Tuscarora, Nev	10	11,000
300 "	Cripple Creek, Col	10	6,300
1000 "	Hiroshima, Japan	15	11,500
8000 "	Minneapolis, Minn	10	11,000

Many of these lines have been in operation for several years, and we have yet to learn of a fatal accident resulting from the use of such high voltages. This record is in striking contrast with the popular expectation and fear expressed as to the results, when such lines were first proposed.

The Spanish War led to an increase in our business in the items of searchlights, cables, marine dynamo sets, etc., considerable as to each item, but small in proportion to our total business.

The increased business of the past year has considerably increased the burden upon our department and local office managers and selling agents whose faithful and efficient work is deserving of commendation.

Respectfully submitted,

EUGENE GRIFFIN,
First Vice-President.

THIRD VICE-PRESIDENT'S REPORT.

Schenectady, N. Y., April 25, 1899.

C. A. Coffin, Esq., President, General Electric Company:

Sir—I submit herewith a report on manufacturing and engineering for the fiscal year ending Jan. 31, 1899.

MANUFACTURING.—The method of determining our factory costs which has proven satisfactory in previous years, has been continued during the present year, such factory costs including all material and labor plus a percentage to cover general expense items and an ample allowance for depreciation. The inventories have been most carefully taken. Financial statistics relating to factory investment are given in the report of the second vice-president. Large additions have been made to our manufacturing plant, and others are now in progress. At the Schenectady Works the large iron foundry mentioned in last year's report as in course of erection, was completed last summer and is now fully occupied. A brick and steel machine shop, covering three and one-fourth acres (142,000 sq. ft.) was begun last June and is now being equipped with the necessary machinery. This large shop will provide unsurpassed facilities for the economical production of the largest apparatus, the demand for which is increasing steadily. Extensions amounting to about 40,000 sq. ft. have been made to other existing buildings, including a suitable building for the safe storage of our valuable patterns. At the Lynn Works the capacity of the steel foundry has been increased 40 per cent, and we have in construction a new building for the manufacture of meters and instruments, the total addition amounting to 35,000 sq. ft.—all substantial, well-lighted, brick buildings. At the Harrison Works, we have, in order to meet the increased demand for incandescent lamps and to improve our facilities, started a new fireproof, four-story building containing about 60,000 sq. ft., which will be completed this summer.

The area of the factory buildings now in use aggregates 1,800,000 sq. ft. (41.3 acres enclosed), and the number of employees now at work is about 9000. In addition to the buildings mentioned, we have expended about four hundred thousand dollars ($400,000) for machinery and tools in the complete equipment of the new buildings and to maintain existing machinery at the point of maximum efficiency and economy.

ENGINEERING.—The demand for electrical machinery of large capacity and special design has continued to increase. A number of the great electrical generators (5000 h.p.) for the new station of the Metropolitan Traction Company at New York, have been completed, and we have under construction an additional order for similar machines, including the transformers and rotary converters to be used in transforming the alternating current into continuous current for the operation of the electric street cars in the borough of Manhattan. The equipment by us of the Buffalo & Lockport Railway with electric locomotives for handling freight, and motor cars for passenger service, is interesting as an instance in which the steam locomotive has been completely displaced by electricity both for freight and passenger service.

The number of installations using alternating generators, in a single generating station, and supplying through our rotary converters, located at convenient distributing points, continuous current for light and power, as described in my last report, has been added to during the year by installations at Philadelphia, Boston and other places. Plants involving the transmission of electricity to long distances have continued to increase in number, those already in operation having been found economical and reliable. We have now in operation about forty long distance transmission plants, employing potentials of from 10,000 volts to 40,000 volts and transmitting power from 10 miles to 80 miles.

About two-thirds of the power required for operating our Schenectady Works is now regularly supplied from a water power at Mechanicsville on the Hudson River, 19 miles away; the production of electricity at high pressure directly in the stationary armature winding of the generators used in this transmission, has, as anticipated, been successful, and has been followed in other similar installations because of its economy and simplicity.

A notable illustration of the flexibility of long distance electric transmission is to be found in the supply of Salt Lake City with electricity from two generating plants, located some 50 miles from each other, the energy being united so as to simultaneously supply electricity over the same set of mains.

The St. Anthony Water Power Company's plant, mentioned in my previous report, has operated so successfully since its installation that additional apparatus to bring the total up to about 10,000 h.p. has been ordered during the past year.

The apparatus for use in the 80-mile transmission to the city of Los Angeles, Cal., mentioned in my last report, has been in successful operation for some months.

Many important orders for electric locomotives, large generators, etc., have been secured in competition with various European manufacturers.

Confidence in the reliability of electrical apparatus is now well established and a general appreciation of its simplicity, flexibility and economy has resulted in a rapid increase in the use of electric motors in older fields and the opening of new. Electric motors are therefore being used in increasing numbers for the driving of machine tools in large and small factories, presses in printing establishments, for ventilating, pumping and mining operations. We have designed many motors specially adapted for such work during the past year.

Our engineers have been actively engaged during the past year in developing the apparatus and details required in new work and in improving and reducing the cost of existing standard lines of apparatus. Numerous improved forms of transformers, arc lamps, meters and instruments, have also been introduced.

We have continued to protect our new designs as far as possible by applications for letters patent.

The work of our factory managers and engineers is worthy of the highest commendation.

Respectfully submitted,

E. W. RICE, Jr.,
Third Vice-President.

SECOND VICE-PRESIDENT'S REPORT.

From the report of Second Vice-President J. P. Ord the following figures are taken and comparison made with reports of previous years:

CONSOLIDATED BALANCE SHEET.

ASSETS.

Dated Jan. 31.	1896.	1897.	1898.	1899.
Patents and franchises	$8,000,000	$8,000,000	$8,000,000	$4,000,000
Factory plants	3,468,002	3,400,002	3,400,002	3,400,002
Real estate (other than factory plants)	453,585	643,016	586,529	615,035
Stocks and bonds	5,479,332	8,545,796	7,455,873	7,226,422
Notes and accounts receivable	6,584,123	4,578,601	4,537,301	5,086,680
Work in progress	961,386	517,866	283,832	507,336
Inventories	4,219,884	4,034,753	3,860,553	4,882,238
Cash	879,686	703,484	1,425,875	1,456,794
Profit and loss (deficit)	13,917,071	12,957,413	11,725,561	--------
Totals	$43,963,069	$43,380,931	$41,275,526	$27,174,507

LIABILITIES.

Capital stock, common	$30,460,000	$30,460,000	$30,460,000	$18,276,000
Capital stock, preferred	4,252,000	4,252,000	4,252,000	2,551,200
5 per cent. gold coupon debentures	8,750,000	8,000,000	6,000,000	5,700,000
Accrued interest on debentures	72,916	66,666	50,000	47,500
Accounts payable	428,153	402,265	263,526	431,496
Unclaimed dividends	--------	--------	--------	11,739
Mortgages	--------	200,000	--------	--------
Reserve for extension to factory plants	--------	--------	250,000	--------
Profit and loss (surplus)	--------	--------	--------	156,571
Totals	$43,963,069	$43,380,931	$41,275,526	$27,174,507

CONSOLIDATED PROFIT AND LOSS ACCOUNT.

EARNINGS.

Years ending Jan. 31.	1897.	1898.	1899.
Sales	$12,540,994	$12,396,093	$15,679,431
Royalties and sundry profits	279,402	128,845	792,591
Interest and discount	88,336	90,371	119,954
Dividends and interest on securities owned	282,144	299,418	342,000
Profit on sales of stocks and bonds	79,817	116,356	324,462
Discount on debentures purchased and canceled	57,139	14,015	2,422
Balance brought forward	12,957,413	11,725,561	--------
Totals	$26,285,245	$24,770,660	$17,260,859
Balance from previous year	$13,917,071	$12,957,413	$1,840,761
Cost of goods sold	9,691,501	9,241,822	11,275,612
General expense and taxes, sundry losses and allowances	1,834,419	1,654,757	1,818,922
Patents and patent expenses	349,919	333,335	269,440
Interest on debentures	431,250	333,333	290,000
Depreciation of inventories	50,355	--------	--------
Depreciation of consignments	10,730	--------	--------
Reserve for factory extensions	--------	250,000	--------
Dividends on preferred stocks	--------	--------	1,609,552
Balance	--------	--------	156,571
Totals	$26,285,245	$24,770,660	$17,260,856

Large Register Order in St. Louis

The consolidation of the principal lines in St. Louis has been followed by a careful consideration of the field and the placing of a number of orders for the new equipment necessitated by increased traffic. One of the first of these orders to be placed was that for registers and was secured by Mr. Carson, president of the Sterling Supply & Manufacturing Company. The order was placed by Mr. Coleman, general manager of the St. Louis Traction Company, the corporation which will operate the lines controlled by Alexander Brown & Sons, and the type specified was the double recording register. This register was described in the last issue of the STREET RAILWAY JOURNAL, and is arranged so that it can record both cash fares and transfers.

The order was one of the first to be placed by the new company and Mr. Carson is to be congratulated upon the recognition secured for the new Sterling double register.

Cord for Arc Lamps and Trolley Cars

The Samson Cordage Works, of Boston, Mass., are devoted exclusively to the manufacture of cords and small ropes for suspending arc lamps, etc., and for use with trolley poles on electric cars. The Samson cord is made from the very best cotton yarns, and is guaranteed free from waste stock. It is braided and finished by the Samson patented and secret process, and is inspected with great care to insure freedom from flaws.

The Samson cord is the result of thirty years' experience in the manufacture of small braided cords, and it is easily distinguished by the colored spots which are woven at frequent intervals through the surface of the cord. When desired, the cords are treated to a coat of waterproofing, that greatly adds to their durability when the material is used where it is subjected to excessive moisture.

Electrical Exhibition at Madison Square Garden

Final arrangements for the electrical exhibition to be held at Madison Square Garden, New York, during May, are being completed. This exhibition promises to exceed in number of exhibits and public interest any previous electrical show that has been held. One of the most prominent features of the 1899 exhibition will be the display of automobiles, and it is thought the exhibit of electrical vehicles will be by far the largest and best ever seen in America, and second only to the great exhibits at Paris. Another interesting feature will be the wireless telegraphy experiments and instruments. The experiments in wireless telegraphy will be more extensive than the ones last year and arrangements have been made for sending messages between different points in the Garden and also from the Garden to points of interest in different parts of the city.

Several valuable Government exhibits have been secured and these will be grouped and attractively displayed. They include apparatus from the army and navy, the signal corps and the weather bureau, and will embrace also not a few interesting relics of the war with Spain.

Recent Consolidations

The air is still full of rumors of consolidations and combinations of street railway companies, many of them simply reports but a number of them well defined. Among the latter may be briefly mentioned the following cities where negotiations are either completed or are well under way.

In Chicago, the Chicago Consolidated Traction Company has made application for the listing of 150,000 shares of its capital stock on the Stock Exchange. This company was chartered Jan. 28, 1899, and in February, 1899, acquired by purchase the entire property of the following named companies: Chicago Electric Transit Company, North Chicago Electric Railway Company, Chicago & North Shore Street Railway Company, North Side Electric Street Railway Company, Evanston Street Railway Company, Cicero & Proviso Street Railway Company, Ogden Street Railway Company, and the Chicago & Jefferson Urban Transit Company. This company has a capital stock of $15,000,000 and the funded debt is $6,085,000, all bonds of the underlying companies.

It is also reported that negotiations which have been in progress for a long time for the consolidation of the larger street railway systems of Chicago have been practically completed. This plan does not contemplate the purchase of the three large companies operating south of Seventy-first Street, i. e., South Chicago Street Railway Company, Calumet Electric Street Railway Company, and the Chicago Electric Traction Company, but does include the Chicago City Railway Company, the North Chicago Street Railroad Company and the West Chicago Street Railroad Company.

In St. Louis, the St. Louis Traction Company has been organized for the purpose of purchasing several street railway properties in the city. In addition to this, the stock of the Lindell Street Railway Company has been increased from $2,500,000 to $10,000,000, which is said to be the preliminary step to the consolidation of all the lines in the city.

All the gas and electric lighting plants in the city of Washington, with the exception of the property of the Capital Traction Company, have been purchased by a syndicate composed chiefly of Baltimore capitalists. It is stated that the purchased roads will soon be consolidated under one system. It is understood that the companies effected are the following: Anacosta & Potomac River Railway Company, the City & Suburban Railway Company, the Georgetown & Tenallytown Railway Company, the Metropolitan Railroad Company and the Washington & Great Falls Electric Railway Company.

As stated in another column of this issue, the Brooklyn Rapid Transit Company has absorbed several additional companies, and now controls practically every street railway and elevated railway line in the borough of Brooklyn, with the exception of the Coney Island & Brooklyn Railway Company.

Société des Tramways Unis de Bucharest is the title of a new company organized at Brussels for operating the tramway system of Bucharest, Roumania. The capital is 8,000,000 fr., and the directors are Josse Allard, Brussels; Eugène Baelde, Saint-Josse-ten-Noode; Hector de Backer, Brussels; Emile Costinesen, Bucharest; Maurice Blanck, Bucharest; Alexandre-Grégoire Jenescu, Bucharest; Samuel Kocherthaler, Berlin; Lucien Van de Vin, Brussels, and Charles Charlier, Brussels.

Railroads in Cuba

The National Railway Publication Company, of New York city, publishers of the "Travelers' Official Railroad Guide," has issued a supplement, giving complete maps, timetables, and lists of officers of all railroads and steamship lines in Cuba. The supplement also contains a page of very interesting notes on the general characteristics of the island of Cuba, with special reference to the conditions of travel by railroad. In part it says:

"The railways are not far behind the times when the conditions by which they have been surrounded and the traffic they have to provide for are carefully considered. The right of way is fenced in, if that is a proper term to use for cactus hedges and stone walls. The roads are laid with steel rails, from 50 to 62 lbs. to the yard, joined with fishplates, with rock ballast, and generally well tied and surfaced. The passenger trains are equipped with air brakes. The freight cars are of smaller dimensions than cars recently built in the United States, and more like those of thirty years ago. The transportation of baggage is paid for, the baggage system resembling that in use on European railways. Three instances will serve to illustrate the rates charged: From Havana to Cardenas, 105 miles, the charge for a trunk of moderate size and weight is $1.30 in Spanish silver, including crossing the ferry from Havana to Regla; from Cardenas to Cienfuegos, 118 miles, the charge is $1.20 in Spanish silver; and from Cienfuegos to Matanzas, 135 miles, the charge is $1.90 in Spanish silver. These charges in American money are equal respectively to 78 cents, 72 cents and $1.08. The railroad fares are generally about five cents a mile in United States money, which means about eight cents a mile in Spanish silver.

"The passenger cars are well adapted to the climate, as well as to the service for which they are intended. Each train, as a rule, consists of three coaches, respectively first, second and third class, although the classes are occasionally divided by partitions in the same car. The conductors and employees on the railroads are usually intelligent, polite and well versed in their duties. On most of the roads buffet lunches are served en route at reasonable prices. Cab fares and porter fees are said to be very reasonable."

Exhibition at Philadelphia

Of the numerous national and international expositions projected for the next three or four years in different parts of the United States, the one to be held in Philadelphia in September, October and November of the present year is in many respects the most important to the trade and commercial interests of the country. The Philadelphia Exposition of 1899 will be an exposition for the development of American manufactures and the expansion of the American export trade and it will be the first national exposition of that character ever held in the United States. The exhibit will be conducted under the joint auspices of the Philadelphia Commercial Museum and the Franklin Institute. The Exposition grounds are situated on the west bank of the Schuylkill River, south of the South Street Bridge and embrace a valuable tract of land of 56 acres in extent, deeded to the Commercial Museum by the city of Philadelphia. The grounds are easily accessible and the buildings are so arranged as to give the greatest convenience to exhibitors and visitors. The Congress of the United States, the Legislature of Pennsylvania and the councils of Philadelphia have indorsed this enterprise and the applications for space already received indicate its complete success.

New Transfer Arrangement in New York

Announcement was made recently that the Third Avenue Railroad Company and the Manhattan Elevated Railway Company, of New York City, had signed an agreement whereby transfers were to be issued to each other's lines at an additional cost to the passenger of 3 cents. The agreement was reached after careful consideration of the probable results, and it is thought the new arrangement will be exceedingly far reaching in its effect upon the traffic of both systems.

The portion of the city most directly benefited by the new transfer arrangement will be the upper part of Greater New York lying in the borough of The Bronx, as it will be possible for a resident of that portion of the city living anywhere near the lines of the Union Railway Company to reach City Hall or the Battery for 8 cents for the trip, and in comparatively good time. This he can do by riding to the northern end of Third Avenue on the electric cars of the Union Railway, and there transferring to the Third Avenue Elevated for an additional fare of 3 cents.

The better traveling facilities secured by the new system will, of course, be shared by the residents of Manhattan Island, though perhaps to a lesser degree. By means of the 125th Street cross-town line and the Forty-second Street and Amsterdam Avenue lines, it will be possible to go from the lower east side to the upper west side, and from the lower west side to the upper east side, or vice versa, for 8 cents instead of 10. Transfer tickets will be issued from the elevated stations to passengers that have paid their fare on the elevated, and from the surface cars to passengers that have paid their fare to the Third Avenue Railroad Company. Over 3,000,000 transfer tickets were required to inaugurate the system.

Metropolitan Street Railway's Rapid Transit Offer Withdrawn

In the last issue of the Street Railway Journal was printed the proposition of the Metropolitan Street Railway Company to the Board of Rapid Transit Commissioners to build an underground railroad in New York for the purpose of furnishing rapid transit to all parts of the city. On April 17, however, the attorneys of the Metropolitan Street Railway Company sent the following letter to the Board, withdrawing its offer for the reasons given:

"Since attending the meeting to which you invited us, with our clients, this afternoon, we have considered the situation as it was then presented, and determined upon the action then indicated to you orally.

"You will remember that at the time of making our proposition of March 27, to build an underground rapid transit railroad, we advised you that our clients considered the difficulties and risks of the undertaking so great that they were not willing to assume them unless assured of popular approval and support; and the correspondence was made public in advance of any action upon it with the understanding that, if it did not prove to be really acceptable to the people of this city, we were to be at liberty to withdraw the offer at any time.

"We made the proposal as advantageous for the city as we consistently could, with a reasonable prospect of profitable investment, and so favorable to the city that from the figures made by our experts as to cost and carrying capacity, the profits seemed to our clients doubtful, and their desire to make the investment, even under the most favorable circumstances, was but slight. While the proposition seemed at first to be received with general approval, and in many quarters was treated in the same spirit in which it was made, we are forced to recognize, and you agree, that criticisms often originating in adverse interests, and attacking the only details of the plan which gave any prospect of profit, have made a lodgment in the public mind, and created an impression that we are trying to drive a hard bargain, and get possession of privileges of great value without rendering an adequate return. Our clients are not willing to occupy this position, and they are satisfied that under such circumstances success in the enterprise would be impossible. They are not willing on these terms to undertake to provide a sum which they estimate at fully $60,000,000, with the certainty of changes in financial conditions long before the work is done and to invest in a novel enterprise of doubtful profit.

"They therefore feel constrained to withdraw their proposition to build the underground rapid transit railroad.

"As you are aware, that proposition had its origin not merely in our clients' wished-for profits, but in a natural inclination to continue and perfect the system of passenger transportation in this city to which they have devoted a great part of the last fourteen years, with results not only profitable to them, but beneficial to the public, and which they could not have accomplished except for the approval and support generously accorded to their efforts by the people of the city. They wish us to express their appreciation of the courtesy and consideration with which you have received and treated them throughout the negotiations."

Death of M. K. Bowen

Menard Kenner Bowen, president of the Chicago City Railway Company, died on Sunday evening, April 9, shortly after an operation for acute appendicitis. He left his office Friday afternoon in his usual health, intending, the following day, to start for Colorado Springs upon a holiday, but in the evening severe pains came on and at a consultation of physicians at midnight, the trouble was recognized as appendicitis and in an advanced stage, and it was determined to remove him to the Chicago Hospital for an operation. This was performed Saturday morning at an early hour, but the disease had progressed too far to be checked, and although the patient rallied after the operation and made a hard struggle for life, the end came at about nine o'clock Sunday evening.

The funeral on Wednesday was one of the most impressive ever seen in Chicago, by reason of the presence in the assembly at Mr. Bowen's residence of many hundred street railway employees, as well as some of the wealthiest and most prominent citizens of Chicago. An escort of 800 men in the train service department of the Chicago City Railway, with the band of the Cottage Grove Avenue Trainmen's Association playing a funeral march, accompanied the body to the train for Jackson, where it was to be interred. The entire procession was over half a mile long. Mr. Bowen leaves a widow and two children, twelve and four years old, respectively.

It is probable that few street railway managers have so fully won the confidence and affectionate regard of their employees as M. K. Bowen. When he became superintendent of the Chicago City Railway in 1891, it was determined by the employees, then a rough, heterogeneous mass of men of all nationalities, and practically all members of labor unions, to make the new superintendent's work as hard as possible, and, in fact, to "run him out of town." Instead of accomplishing this, the unruly element was weeded out, and a strong and coherent body of employees was formed, which quickly came to look upon Mr. Bowen as an absolutely fair-minded, straightforward man, on whose sense of justice they could rely and whose magnificent ability as an organizer and manager they could admire. Mr. Bowen has rarely failed in carrying out any plan which he had at heart, and his directors recognized his services by advancing him from the position of superintendent to that of general manager, and eventually of president of the company—a company, one of the strongest and most prosperous in the United States. It is characteristic of the man that when early on Saturday morning he knew that the operation must be performed, and realized as others did not that the result of his long struggle of years against disease was likely to be fatal, he put aside his own pain and trouble long enough to send for Superintendent Nagle, of the Chicago City Company, to whom he gave some final directions concerning its management, and bade farewell.

M. K. BOWEN

Mr. Bowen was a man in the prime of life, being but forty-one years of age. His father was Gen. John S. Bowen, a graduate of West Point, and his grandfather, Pierre Menard, first Lieutenant-Governor of Illinois. He was educated at St. Louis and Washington Universities, and at the age of nineteen, entered the Government service as assistant engineer in civil engineering work on the Mississippi River. In 1880 he was engineer in charge of the topographical survey of the St. Louis & San Francisco Railway from Fort Smith, Ark., to California. He first became identified with street railway work in Kansas City, becoming chief engineer and superintendent of construction for the Kansas City Railway Company, then building its cable line. A little later he became the New York representative of the Short Electric Railway Company, and in 1891 entered upon his eight years' service with the Chicago City Railway Company.

During his connection with this system Mr. Bowen was instrumental in bringing about important changes and extensions. The methods of conducting the business of the company were revised, new lines constructed, old ones rebuilt, and the motive power changed to electricity on all but the trunk lines, which are operated by cables. Mr. Bowen himself made no pretensions to inventive genius, nevertheless he demonstrated his ability to design and improve methods, and his opinion on all matters pertaining to street railway management had come to be highly regarded.

To his many friends in street railway circles, Mr. Bowen's death causes grief as at the loss of a close personal friend. He was singularly winning and generous in his friendships, granting to all credit for the best intentions and rarely taking offence. An unkindly word of another was almost unheard from his lips, for his principle in life seemed to be to "think no evil of any man." He was a rare character and a friend long to be remembered among those who enjoyed his friendship.

Personal

MR. W. R. BENSON has been appointed manager of the Easton Consolidated Electric Company, of Easton, Pa.

MR. C. D. MENEELY has been appointed assistant secretary and treasurer of the Brooklyn Rapid Transit Company.

MR. H. M. BRINCKERHOFF has been made assistant general manager of the Metropolitan Railway Company of Chicago.

MR. JAMES R. CRAVATH, a well-known electrical engineer, was married on April 19 to Miss Ruth M. Rew, at Grinnell, Ia.

MR. WILLIAM P. GANNON has been elected president of the Syracuse Rapid Transit Railway Company, in place of Charles R. Flint.

MR. U. H. McCARTER has entered upon his duties as secretary and treasurer of the New Jersey Electric Railway Company, of Hoboken.

MR. ARTHUR ORR, a prominent Board of Trade operator and capitalist, has been elected director of the Chicago City Railway Company in place of Mr. Bowen.

MR. GEORGE HURD, of Toledo, Ohio, has been appointed manager of the Janesville Street Railway Company, of Janesville, Wis., in place of Fred O. Greene, resigned.

MR. J. L. HINES, formerly president of the New Jersey Electric Street Railway Company, of Hoboken, N. J., has resigned, and has been succeeded by Mr. Chandler W. Riker.

MR. J. W. MEAKER, JR., will open an office in Chicago, where he will handle street railway specialties. Mr. Meaker has for some time been connected with the Meaker Manufacturing Company.

MR. ALBERT S. RICHEY, formerly electrician for the Citizens' Street Railway Company, at Muncie, Ind., has resigned to accept a position as electrical engineer of the Marion City Railway Company and its interurban branches, at Marion, Ind.

MR. G. HARRY GARRISON, secretary and treasurer of the Cortland & Homer Traction Company, of Cortland, N. Y., has resigned his position to accept another one in Troy. Mr. Garrison on the eve of his departure was tendered a farewell banquet by a number of his friends.

MR. FRANK W. CARR has accepted the position of Superintendent of The Falk Company, of Milwaukee. Mr. Carr for some time past has been the chief engineer and superintendent of electrical construction for the West Chicago Street Railway Company, and is a thoroughly well-informed electrical engineer.

MR. L. D. TANDY, one of the engineers of the railway department of the General Electric Company, has severed his connection with that company and sailed for Europe, April 15. Mr. Tandy will make his headquarters in London and will be associated with Messrs. John Hays Hammond and Henry A. Butters in their continental electric railway enterprises.

MR. F. L. HART, until recently general manager of the Baltimore City Passenger Railway Company, has been engaged by the Crosby-Lieb syndicate in Washington as manager of the street railway and electric lighting properties which are now in process of consolidation, and has at once commenced work on the construction of 20 miles of underground conduit track construction.

MR. MAURICE COSTER, for three years manager for the Westinghouse Electric & Manufacturing Company at Chicago, has sailed for Europe, where he will enter upon the duties of general manager of the Société Industrielle de Electricité Procédés Westinghouse, a French company newly formed to manufacture and sell Westinghouse electrical machinery and apparatus on the continent of Europe.

MR. W. F. HAM, formerly secretary of the Nassau Electric Railway Company, has been appointed auditor of the entire Brooklyn Rapid Transit system, and has entered upon his new duties. Mr. Ham is an expert accountant, and has given the subject of street railway accounts most careful study. He was one of the organizers of the Street Railway Accountants' Association, and has been one of its hardest workers since its beginning.

MR. ERVIN G. LONG, vice-president of the Peckham Truck Company, of Kingston, N. Y., was married to Miss Cora A. Reynolds on Wednesday afternoon, April 26, 1899, at Christ Church, Poughkeepsie, N. Y. Mr. Long is one of the best-known supply

men in the street railway field, and his large circle of acquaintances will wish him the heartiest congratulations at this time. Mr. Long has recently returned from a very successful business trip in Europe.

MR. FRANK X. CICOTT, who was well known in electrical and tramway circles on both sides of the Atlantic, died recently at the home of his sister in Detroit. Mr. Cicott had just returned from a trip around the world, undertaken to investigate the possibilities for the investment of American and European capital in tramway enterprises abroad, and some articles from his pen on foreign practice have appeared in recent issues of this paper. Mr. Cicott was at one time director of the United States Government mint at San Francisco.

MR. BURT VAN HORN has received the appointment of general manager of the International Traction Company, of Buffalo. As announced in the last issue of the STREET RAILWAY JOURNAL, this company is completing the consolidation of a number of street railway companies in the city of Buffalo and vicinity, and the combined system will be one of the largest in the East. Mr. Van Horn is well known to the street railway fraternity, and he enjoys the reputation of being an exceptionally able and well-informed street railway manager. He has the best wishes of his many acquaintances in entering upon his new duties.

MR. R. M. DOUGLASS, until this month secretary, treasurer and general manager of the Schuylkill Valley Traction Company, of Norristown, Pa., has accepted the position of general superintendent of the Cleveland Electric Railway Company, having entire charge of the property, under President Everett. Mr. Douglass entered the street railway field about five years ago, his first work being the building of the Syracuse & East Side Street Railway, of which he had general charge until the sale of the property. He then went to the Brooklyn Heights Railway Company as superintendent, but on account of severe and protracted illness he gave up this position in order to take that at Norristown, where he has since been an active and efficient manager.

MR. E. H. CHAPIN, who was formerly connected with the STREET RAILWAY JOURNAL and later with the Standard Oil Company, of New York, has recently opened an office in Rochester, with headquarters in the Granite Building, where he will represent the Burnett Company, of New York, dealers in railroad, electrical, marine, mining and milling supplies, and also the Swan & Finch Company, of New York, refiners and dealers in lubricating oils and grease. This latter concern has been engaged in the manufacture of oil and grease since 1853, and is well known in the trade. Mr. Chapin's energy and popularity insure a successful business in anything which he undertakes and in his new business he has the best wishes of his former co-workers on this publication.

MR. DAVID G. HAMILTON, the new president of the Chicago City Railway Company, succeeding Mr. Bowen in that position, is one of the best-known street railway men in the United States, having been for many years a regular attendant at the conventions of the American Street Railway Association, where his advice and counsel have always been sought and have had great weight. As Mr. Hamilton has been the responsible financial head of a half-dozen or more street railway properties in St. Louis of which Mr. Robert McCulloch has been the chief executive, and his street railway experience, gained partly in this connection and partly as a large stockholder and director, and latterly second vice-president, of the Chicago City Railway Company, has been intimate and wide. Mr. Hamilton was born in Chicago in 1842, and nearly all his life was spent in that city. He studied law at the old Chicago University, and entered upon a practice later on, but after a number of years he became interested as investor and financier in many important financial undertakings in Chicago, and especially in real estate. He is Western director of the Union Life Mutual Insurance Company, of Maine, a member of the board of trustees of the University of Chicago and of De Pauw University, and is a member of several clubs of Chicago.

AMONG THE MANUFACTURERS

THE EDW. P. ALLIS COMPANY, of Milwaukee, Wis., has just booked a large order from Russia for mining and pumping machinery.

PEPPER & REGISTER, of Philadelphia, Pa., have removed their offices to rooms 712 and 715 Fidelity Mutual Life Building, North Broad Street, Philadelphia.

THE Q. & C. COMPANY, of New York city, is about to make extensive shipments of pneumatic tools to Russia, Paris and London. This company is doing an excellent foreign business.

E. F. DE WITT & COMPANY, of Lansingburg, N. Y., manufacturers of the "Common Sense" sand box, have appointed the W. R. Garton Company, of Chicago, Western agents for these sand boxes.

DICK BROS. & CO., bankers, of New York and Philadelphia, announce that William R. McLaughlin, formerly of the "Electrical World," will represent them in the placing of investment securities.

THE JACKSON & SHARP COMPANY, of Wilmington, Del., reports that it is exceptionally busy at this time, having more orders for both open and closed car bodies than it has had at any one time in years. This company has also just shipped some large double truck, double deck cars to the Argentine Republic.

THE B. F. STURTEVANT COMPANY, of Boston, Mass., is sending out Bulletin M, which is devoted to the Sturtevant electric propeller fans, for ventilating buildings of all classes, smoking and dining rooms, restaurants, kitchens, bakeries, boiler rooms, etc.

THE ELECTRICAL INSTALLATION COMPANY, Monadnock Block, Chicago, announces to the trade in a handsomely engraved notice that after May 1 it will be at home to its friends in new offices at 1516 and 1517 Monadnock Block, directly over and four floors above its old location.

THE HENRY R. WORTHINGTON PUMP WORKS, of New York, are well filled with foreign orders, and their weekly shipments to Europe average two carloads. This concern will furnish the pumping machinery which is to furnish the water supplied for the coming Paris Exposition.

THE JEWELL BELTING COMPANY, of Hartford, Conn., has completed and has ready for shipment two leather belts which were ordered by a firm in a leading city in France. The belts are ½-in. in thickness, 5 ft. in width, and together are 225½ ft. long. They weigh over 2400 lbs. and will undoubtedly be the widest belts in France.

THE ABENDROTH & ROOT MANUFACTURING COMPANY, of New York, manufacturer of the Root improved water tube boiler and Root's spiral riveted pipe, on May 1, removed from its former location at 28 Cliff Street, to the new building erected at 99 John Street, where it will occupy commodious offices on the sixth floor.

THE EDW. P. ALLIS COMPANY, of Milwaukee, Wis., will furnish two 750-h.p. direct connected vertical cross compound condensing engines to the North River Light, Heat & Power Company, of Hoboken, N. J., and two direct connected cross compound condensing engines of 300 h.p. and 450 h.p., respectively, for a new electric railway at Lebanon, Pa.

WILLIAMSON & COMPANY, of Allegheny, Pa., have published a descriptive catalogue of the Ramsey signal system. This system is now well known to electric railway managers, and is in operation on many single track roads. The catalogue contains a number of interesting testimonial letters, and also a complete diagram showing the working of the system.

THE TURNER ENGINEERING COMPANY, of Bucyrus, Ohio, is furnishing the "Turner" water tube boiler, 250 h.p., for the Findlay Ohio Street Railway; two 200 h.p. for the Central Traction Company, and three 225 h.p. for the Indianapolis Ice & Cold Storage Company. Large boilers of this type recently put into service are showing excellent results.

THE WESTERN ELECTRICAL INSTRUMENT COMPANY, of Newark, N. J., is making contracts for its new factory at Waverly, N. J., a suburb of Newark. A railway switch has been constructed to the spot, and ground was broken recently for the erection of what will be one of the most complete manufacturing establishments in the United States.

JOHN E. DE LEON, of Buffalo, N. Y., after numerous experiments, has perfected a unique electrical exhibition for street railway parks and pleasure resorts. His exhibition consists of several feats upon a bare wire cable charged with electricity. The cable and his body are outlined with numerous incandescent lights of various colors, and some very startling and attractive results are secured.

THE DUPLEX CAR COMPANY, of New York, has found it necessary to extend its factory capacity, on account of the number of orders received. Many of the cars this company is building for foreign delivery are arranged with a single seat on one side of the aisle and a double seat on the other. The officers of the company report excellent prospects for a large business during the next few months.

THE DORNER TRUCK & MANUFACTURING COMPANY, of Cleveland, Ohio, has received an order for trucks from the Cleveland & Eastern Railway Company. The truck used will be the company's latest type, No. 15 Criterion pivotal motor truck. The Dorner Truck & Manufacturing Company also has some good orders for its No. 11 Criterion single motor truck, and two orders of ten trucks each for its new Moore truck.

THE FRANK M. PIERCE ENGINEERING COMPANY, of New York city, has closed a contract with the Amsterdam Street Railway Company, of Amsterdam, N. Y., to install a 250-h.p. Erie Ball engine to be direct connected to two 80-kw. G. E. generators. The Frank M. Pierce Engineering Company has also shipped a 100-h.p. engine for electric work at a mining plant in North Japan; also two 125-h.p. engines to the same country.

WINTHROP G. NORRIS & COMPANY, of Boston, Mass., have completed plans and specifications for a power station and car barns for the Gardiner, Westminster & Fitchburg Railway Company. This will be a direct connected station, with Slater compound condensing engines. The road will be 9 miles in length with a branch of about 2 miles from South Fitchburg to Wauchusett Lake. The work will be pushed rapidly to completion.

CHANGE OF OWNERSHIP.—It is announced that all the capital stock of the Commercial Electric Supply Company, of St. Louis, Mo., has been purchased by William F. Nolker, his sons and associates. Mr. Nolker proposes to increase the capital stock of the company and to place the Commercial Electrical Supply Company in a very enviable position. The management and general personnel of the company will remain about as heretofore.

THE BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., has taken the contract for the new roof on the East Armory of the Colt's Fire Arms Manufacturing Company, at Hartford. This roof is 60 ft. wide and 500 ft. long, and is to be entirely recovered. The new roofing is to be the Berlin Iron Bridge Company's anti-condensation fireproof roof lining, consisting of anti-condensation lining underneath the corrugated iron outside covering.

THE ERICSSON TELEPHONE COMPANY, of New York, has moved its offices from 20 Warren Street to 296 Broadway. This company's specialties have been sent to a large number of cities of this and foreign countries, and the Ericsson telephones need no introduction. The company's latest catalogue contains interesting descriptive matter on the different types of receivers and transmitters and telephone sets that are carried in stock.

THE AMERICAN RAIL JOINT & MANUFACTURING COMPANY, of Cleveland, Ohio, has closed contracts with the Erie & Cambridgeboro Electric Railway Company for joints on about 25 miles of track; with the Orleans & Jefferson Railway Company for 9 miles, and the Kansas City & Leavenworth Railway Company for 11 miles; a total of about 21,000 joints. This company so far this season has made contracts for about 40,000 joints.

THE ELECTRICAL INSTALLATION COMPANY, of Chicago, is furnishing the overhead construction for the Northeast Electric Railway of Kansas City, and the Grand Avenue division of the Brooklyn Avenue Railway Company of Kansas City, and also about a thousand iron poles for the Metropolitan Street Railway Company of Kansas City. It has also recently secured a contract for building an extension to the Vicksburg Electric Railway, Vicksburg, Miss.

C. TOWNSEND BLAKE, of Philadelphia, Pa., reports that he is now installed in his new offices at 612 Girard Trust Building, Philadelphia, and is prepared to transact business in his former prompt manner. He is prepared to buy and sell and to quote prices on all unlisted street railway, steam railroad and gas bonds. In addition to this he has opened a municipal department under the management of Robert Hancocks, and will be pleased to negotiate either for the purchase or sale of any issue of municipal bonds.

LAING, WHARTON & DOWN, LTD., of London, are sending out a neat catalogue describing the Vril electric launches, which are manufactured by this firm. These launches are operated by storage batteries, and the machinery is fitted in water-tight compartments, taking up no room that can be occupied for passenger accommodation. During the time the launch is running the machinery requires little attention, and is free from danger. The services of but one man are required to both control the machinery and steer.

THE GARTON-DANIELS ELECTRIC COMPANY, of Keokuk, Ia., is sending out some interesting leaflets describing Garton lightning arresters. A paragraph from one of these is particularly worthy of note. It is as follows: "Use plenty of pole arresters—they cost much less than repairs, and do not require constant attention. Never ground your lines. Offer the discharge many paths to earth before coming to your station. Relieve the strain on the insulation of your entire system." The manufacturers of the Garton arresters claim that these instruments contain all the desirable features of a lightning protective device.

SPECIAL CATALOGUE.—The Peckham Truck Company, of Kingston, N. Y., and New York city, has just issued another one of its series of elaborate and valuable catalogues. This one is devoted to the Peckham system of single electric trucks, and consists of fourteen sheets, 15 ins. x 8 ins., of heavy paper bound together with fasteners, with heavy covers. Upon one side of each sheet is printed a handsome engraving of some special type of single truck, and on the opposite side of many of the sheets appears an engraving of a car mounted upon that particular truck. The engravings of the trucks are printed with tinted background, and the details of all the parts are clearly brought out. This company has also issued a catalogue of the same general style devoted to double trucks.

MERCHANT & COMPANY (Inc.), of Philadelphia, New York and Chicago, have recently received an order from the War Department for 786 of their galvanized "Star" ventilators, for use on the officers' quarters and barracks to be erected at Havana and Matanzas, Cuba. There will be 587 "Star" ventilators, 24 ins. in diameter, and 199, 14 ins. in diameter. Some idea of the size of the order can be had, when it is stated that if these ventilators were placed in a line with their edges touching, they would cover a distance of nearly half a mile. Within the last few months Merchant & Company (Inc.) have also supplied 500 ventilators, 18 ins. in diameter, for the new government hospitals at Fortress Monroe and Savannah.

THE KEUFFEL & ESSER COMPANY, of New York city, the well-known manufacturers of everything required in the science of drawing and measuring, report a constantly increasing demand for their goods. This company is known throughout the world, and its goods are recognized as standard by a very large number of leading architects, surveyors, draftsmen, etc., of the country. This firm makes most of its goods in its own factory and absolutely controls nearly all goods which it imports. It warrants all materials and instruments to be exactly as represented. Its profusely illustrated catalogue of over 400 pages should be in the hands of everyone interested in any way in drawing or measuring instruments or materials, and this pamphlet will be sent free of charge on request.

THE W. R. GARTON COMPANY, of Chicago, of which W. R. Garton is president and treasurer, and Ray P. Lee is secretary, has just moved into its new quarters, suite 603-604 Manhattan Building, where it enters the second year of its existence under the most auspicious of circumstances. This company represents, among others, the Electric Railway Equipment Company, of Cincinnati, Ohio, whose exceptional line of iron and steel, tubular and ornamental poles, brackets and trimmings, as well as a most complete line of figure 8, and round trolley, overhead material is so well and favorably known. The W. R. Garton Company has closed several very large contracts in these lines; in fact, reports a business for the various manufactures whom its represents of over $50,000 during the last forty days.

A WELL-KNOWN SUPPLY AGENCY.—Charles N. Wood, of Boston, Mass., agent and representative for many of the leading street railway supply houses in America, reports a constantly increasing business. Mr. Wood has recently formed a consolidation with the Frank Ridlon Company, with offices at 200 Summer Street and 31 State Street, Boston, and this has resulted in a very large increase of orders. Among the firms represented by Mr. Wood are the R. D. Nuttall Company, International Register Company, American Heating Corporation, Wilson, Thompson & Company, Van Wagoner & Williams Hardware & Mining Company, etc., so he is in a position to execute promptly contracts for almost any specialty required by a street railway company. Mr. Wood's extensive exhibit at the last convention, at Boston, will be remembered by all convention goers.

THE GENERAL ELECTRIC COMPANY, of Schenectady, N. Y., has issued from its press during the past month the following catalogues and circulars: Bulletin No. 4168, describing single-phase alternating current generators, 60-cycle revolving armature type; Bulletin No. 4169, describing the two-rate meter and system; Bulletin No. 4170, running light tell-tale boards; pamphlet by Carl D. Haskins, on the "Management of Central Station Meter Systems;" and an exceedingly tasteful brochure devoted to the subject of fan motors. The latter is profusely illustrated, showing all the various types of alternating and direct current fan motors for ceilings, walls and desks, and other special requirements. The company has also issued Bulletin No. 4106, on direct current lightning arresters, magnetic blowout type, M. D.; No. 4167, on assembled commutator segments for railway motors; and No. 4171, on railway line material.

THE MANHATTAN RAILWAY COMPANY, of New York, has recently placed one of the largest single orders for transfer tickets ever given. This company has made transfer arrangements with the Third Avenue Railroad, and as the system went into effect April 29, it was necessary to have the tickets printed on very short notice. To inaugurate the system many millions of tickets were required, there being 427 stations, each requiring its special ticket. The general style was not decided upon until Tuesday noon, April 18. A special paper was required, therefore it had to be made for the purpose. Geometric lathe work tints had to be engraved, and owing to the work required special machinery had to be arranged. All this had to be done, and at least three million transfer tickets delivered by Tuesday noon, April 25. The work of furnishing these tickets was given to the Globe Ticket Company, of Philadelphia, and the confidence placed in this concern by the Manhattan Railway Company speaks well for its resources and reputation.

THE WESTERN ELECTRICAL SUPPLY COMPANY, of St. Louis, Mo., is pushing the street railway branch of its business this season, and is evidently receiving some very gratifying results. The head of this department, Charles Scudder, Jr., reports some very flattering results and a constantly increasing demand for the company's goods, of which it has a most excellent assortment, and of a quality that will bear inspection. The company is now Western agent for some of the most prominent manufacturers in the country and has taken every precaution in the selection of the goods represented. This has resulted in the company offering to the trade a very high grade of supplies necessary in the construction and maintenance of a street railway. The company is carrying a very complete railway stock in St. Louis, which has been found to be of great assistance and value in sustaining its reputation for prompt shipment, which its experience has shown to be second only to the quality of the goods furnished.

THE WARREN-WEBSTER COMPANY, of Camden, N. J., report the following recent sales of Webster vacuum feed water heaters and purifiers: S. S. Mascotte; Creedmore Mining Company, Creede, Col.; Freemont Electric Light Company, Cripple Creek, Col.; Washington County Court House, Washington, Pa.; St. George's Hotel, Evansville, Ind.; St. Louis Club, St. Louis, Mo.; New York, New Haven & Hartford Railroad Company Depot, Providence, R. I.; Gaensslen Fisher Glue Company, Gowanda, N. Y.; Cleveland Twist Drill Company, Cleveland, Ohio; Masonic Temple, Boston, Mass.; Arapahoe County Poor Farm, Denver, Col.; Winship Machine Company, Atlanta, Ga.; J. R. Keim & Co., Philadelphia, Pa.; Boston Rubber Shoe Company, Malden, Mass.; Walworth Con. & Supply Company, Boston, Mass.; Morris Building Company, Mills No. 3, Brooklyn, N. Y.; Massachusetts Cotton Mills, Lowell, Mass.; Hazard Manufacturing Company, Wilkesbarre, Pa.; Calvin, Pardee & Company, Harwood Colliery, Pa.; Conkling Chemical Company, S. Chicago, Ill.

THE HARRISBURG FOUNDRY & MACHINE WORKS, through their Boston office, have been awarded the contract for furnishing Harrisburg standard engines of a capacity of over 4000 h.p. There are ten engines in the order, each engine weighing 60,000 lbs., which will develop 350 h.p.; maximum capacity 400. These engines are for the immense new plant of the Great Northern Paper Company, which has purchased thousands of acres of timber land, erected enormous buildings and machinery in the northern part of the State of Maine, and which will be the largest paper producing plant in the world. This order is just one-half of the entire order, which will be nearly 10,000 h.p.. This, it is stated, is the largest order for engines of the wheel governing type ever placed in this country, and was obtained in open competition at better prices than were made by other concerns. The Harrisburg Foundry & Machine Works have been so crowded with work as to necessitate running day and night for the last six months, and it is fortunate that their new plant is so rapidly nearing completion, for it is only on account of this that it has been possible for them to accept the present rush of orders.

A. L. IDE & SONS have recently made the following contracts for "Ideal" engines: Fountain City, Wis., one 70 h.p., belted; Monterey Electric Light Company, Monterey, Mexico, one 250-h.p. and one 110-h.p. tandem compound engines, belted; Kingan & Company, Indianapolis, one 70-h.p., direct connected; Emery, Bird, Thayer Dry Goods Company, Kansas City, one 260-h.p., direct connected; the Kuntz-Remmler Company, Chicago, one 45-h.p., belted; Kingman Plow Company, Peoria, Ill., one 100-h.p., belted; Janney, Semple, Hill & Company, Minneapolis, Minn., one 60-h.p., direct connected; Caro Light & Power Company, Caro, Mich., one 300-h.p., belted; Bonham Electric Light Company, Bonham, Tex., one 60-h.p., belted; F. W. Horne, Yokohama, Japan, one 40-h.p., direct connected; Boston Store, Davenport, Iowa, one 100-h.p., direct connected; Pilgrim Hotel, Marshalltown, Iowa, one 60-h.p., direct connected; Illinois Central Railroad Company, Chicago, Ill., one 80-h.p.; Deadwood & Delaware Smelting Company, Deadwood, S. Dak., one 100-h.p., direct connected; Hillman Building, Chicago, one 125-h.p. and one 150-h p. tandem compound engines, direct connected; Illinois State Reformatory, Pontiac, one 200-h.p., belted; Lancaster Electric Light Company, Lancaster, Wis., one 100-h.p., belted; Kieckhefer Bros., Milwaukee, one 190-h.p., direct connected; C. J. Smith & Sons, Milwaukee, one 125-h.p., direct connected; Anheuser-Busch Brewing Association, two 125-h.p., direct connected; Chicago & Great Western Railroad Company, for shops at Oelwein, Ia., one 180-h.p. and one 300-h.p.; City of Barnesville, Minn., one 60-h.p., direct connected; Empire Zinc Company, Joplin, Mo., one 150-h.p. and one 100-h.p., direct connected; Mississippi River Commission, two 500-h.p. tandem compound engines; W. J. Lemp Brewing Company, St. Louis, two 100-h.p. engines, direct connected, and one 60-h.p., direct connected.

New Publications

Circular No. 10. Published by the Street Railway Accountants' Association of America. Paper. 17 pages. Illustrated.

This pamphlet is being sent out from the secretary's office of the Street Railway Accountants' Association, and is a full and clear explanation of the objects, aims, and advantages of the association. To street railway companies desiring to improve and extend the usefulness of their accounting departments this pamphlet will be of considerable interest. The book contains also the constitution and by-laws of the Accountants' Association, with a list of members.

Preliminary Report on the Income Account of Railways in the United States for the Year Ending June 30, 1898. Paper. 70 Pages. Compiled and published by the Interstate Commerce Commission, Washington, D. C.

As stated in the title, this is a preliminary report of the Interstate Commerce Commission on the income and expenditures of railways in the United States, for the year ending June 30, 1898. From this report it appears that the total gross earnings of the railways during the year were $1,238,523,380, an increase over the previous year of $116,433,607. Of the aggregate gross earnings, $332,892,782 are from passenger service and $874,865,487 from freight service. The operating expenses of the roads were $811,-241,458, an increase over the previous year of $58,716,694. The net earnings for 1898 were $427,281,922, an increase of $57,716,913. The total mileage reported is 181,334 miles of track.

Trade Catalogues

Street Railway Journal

VOL. XV. NEW YORK AND CHICAGO, JUNE, 1899. No. 6.

THE ELECTRIC RAILWAY SYSTEM OF MILWAUKEE AND EASTERN WISCONSIN

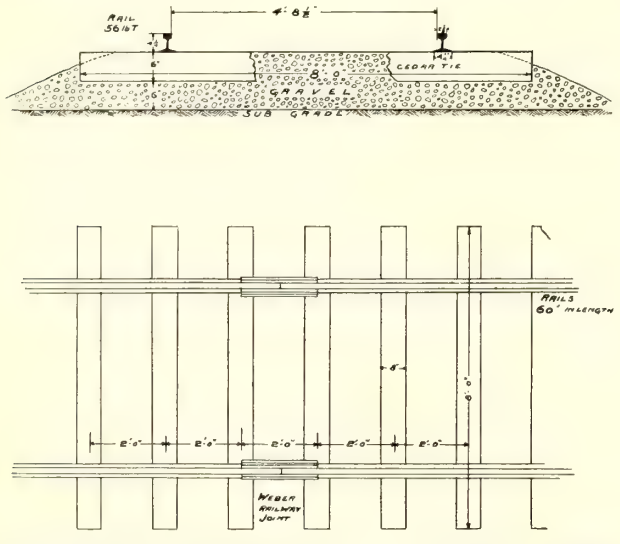
U. JUN 3 1899 S. PATENT OFFICE

In the State of Wisconsin and counties of Milwaukee, Waukesha, Racine and Kenosha lies an electric railway system remarkable in many respects, and the recent development of which is little known to the "outside world." Its nucleus is the city railway system of Milwaukee, which is a consolidation, effected in 1891-2, of several smaller lines until then in independent operation. Additions have been made by the purchase of existing lines and the building of new ones, until now the system reaches out 7 miles to Whitefish Bay on the north; 25 miles to Waukesha Beach on the west, and nearly 35 miles to Kenosha on the south. A dozen cities and villages, with an aggregate population exceeding 350,000, are served by the 225 miles of track which at present comprise this system—a trackage which places this among the half-dozen great properties of the country.

VIADUCT AT WAUWATOSA—MILWAUKEE STREET RAILWAY SYSTEM

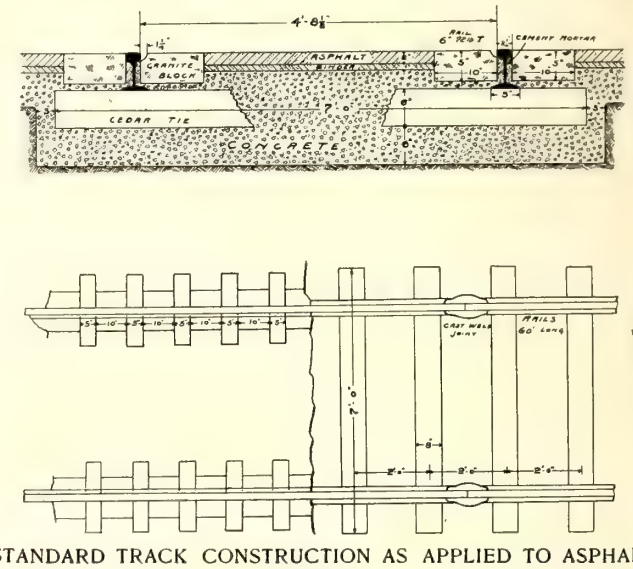
This is not all. The plans of the present management are broad and comprehensive, and include the immediate construction of a line extending from the southern terminus of the present system through to Chicago, connecting there with the Chicago city system; while on the west and north it is intended to push the lines rapidly onward through the beautiful lake district, in which are thousands of summer homes of Chicago, St. Louis and Milwaukee business men.

For financial and business reasons this entire system centering in Milwaukee is operated by two separate companies, the Milwaukee Electric Railway & Light Company, which owns the city lines and does the city and commercial electric lighting, and the Milwaukee Light, Heat & Traction Company, which owns all the interurban lines, and also has electric lighting departments in several of the cities reached by its railway lines. The entire capital stock of the Milwaukee Light, Heat & Traction Company is in the treasury of the Milwaukee Electric Railway & Light Company, and a controlling interest in the stock of the latter is owned by the North American Company, of New York, which also owns a controlling interest in the Cincinnati Edison Electric Company. In practice the two Milwaukee companies are operated as one, although their accounts are kept entirely separate.



RAILWAY FARES AND LIGHTING CHARGES

Within the city limits of Milwaukee a uniform 5-cent fare is charged, and transfers are given freely for a continuous trip. Outside the limits the rates vary from 10 to 60 cents single fare, and 50 per cent is added for the round trip. The fare from Milwaukee to Racine, for example, is 40 cents single trip, 60 cents round trip; from Milwaukee to Kenosha it is 60 cents single trip and 90 cents round trip; from Milwaukee to Waukesha Beach it is 50 cents single trip, 75 cents round trip; and from Milwaukee to Whitefish Bay it is 10 cents single trip, 15 cents round trip. The rate for a private car from Milwaukee to Waukesha Beach is $25 round trip, each car seating fifty passengers,



and the city rates for private cars vary from $5 for the short single-truck car to $15 for the magnificent illuminated car "Marguerite," the rates being based on a three-hour run, with an extra charge for each additional hour.

The charges for lighting are as follows:

For direct current low tension power for lighting circuits, 20 cents per 1000 watt hours, subject to 25 per cent discount for incandescent lamp use up to 125,000 watt hours per month, and 50 per cent discount above that figure. Current for electric motors is charged for at the rate of 10 cents per thousand watt hours, subject to discounts ranging from 5 per cent for use of 100,000 to 200,000 watt hours per month to 50 per cent for use of 1,000,000 watt hours per month. Minimum charges are, of course, provided for by special schedule.

STANDARD TRACK CONSTRUCTION FOR INTERURBAN LINES

STANDARD TRACK CONSTRUCTION AS APPLIED TO ASPHALT PAVING

ROADBED

The traffic earning power of a combined urban and interurban system of this kind is largely dependent on speed of transit in competition with other transportation agencies, and high car speeds are possible only when track and roadbed are in first-class condition, and the lines are reasonably straight. These facts have been fully appreciated by the present management, and the work of straightening the interurban lines and improving the roadbed has been steadily going on for the past two years, and large sums of money have been expended in securing private rights of way to cut off curves, reduce distances between population centers and decrease running time. Other large sums have been spent in grading and leveling roadbed and improving alignment and surface of track, to the end of approaching more nearly to steam railroad standards. Within the city limits a large amount of old chair rail construction has been replaced by heavy T rail sections, laid directly on ties, and in several of the best paved streets, such as Grand Avenue, a concrete foundation is being put under the ties, the whole forming a solid, massive construction, difficult to improve upon.

T RAIL TRACK CONSTRUCTION ON GRAND AVENUE

The standard city roadbed construction is shown on this page, and an illustration is also given of the new work now going on in Grand Avenue. The company is fortunate in being able to use T rail in both city and interurban work, the Milwaukee pavements being such that this can be done without difficulty. The standard rail for city work is a 6-in. 72-lb. Shanghai section, rolled in 60-ft. lengths. Recent purchases have been made of the Johnson Company and the Pennsylvania Steel Company. It is laid on oak ties 6 ins. x 8 ins. x 7 ft., set 2 ft. apart on centers. In pavements which have a concrete foundation the ties are placed on a 6-in. bed of concrete, and on other streets broken stone ballast is used.

About two years ago the first experiments in cast welding joints were made by the Falk Company, and on track which was then so poor that without these improvements its immediate replacement would have been necessary. Today this track is even better than when the joints were put in, in many places having been worn to better surface, and it is believed that the rail was given five or six years' additional life by use of the cast welded joints. By the end of this year all the joints within the city limits, over 40,000 in number, will be cast welded. The original work was done by the Falk Company, whose methods and processes are well known and have proven satisfactory in Milwaukee. Later contracts, however, have been awarded to the Milwaukee Rail Joint & Welding Company, which will, by the end of this year, have installed over 25,000 joints. Their process is somewhat different from that of the Falk Company. A casing or jacket, formed of two L-shaped pieces of rolled steel, is placed under and at the side of the joint and is temporarily fastened to the rail by clamps. The metal is then poured round the joint inside this jacket, after which the clamps are taken off and the jacket remains in position, giving additional strength to the cast iron which it incloses. This company has also successfully placed its joints on exposed rails in the interurban track between Milwaukee and South Milwaukee,

although the full results of this work have not as yet been demonstrated by long time tests. Slip joints are provided, as shown herewith, every 500 ft., and the contraction and expansion of the track has been found to amount to about 1¼ ins. per 100 ft. of track, so that at the slip joints the rails are sometimes 6 ins. apart.

The standard suburban roadbed construction consists of a 56-lb. T rail 4¼ ins. high, rolled in 60-ft. lengths, laid

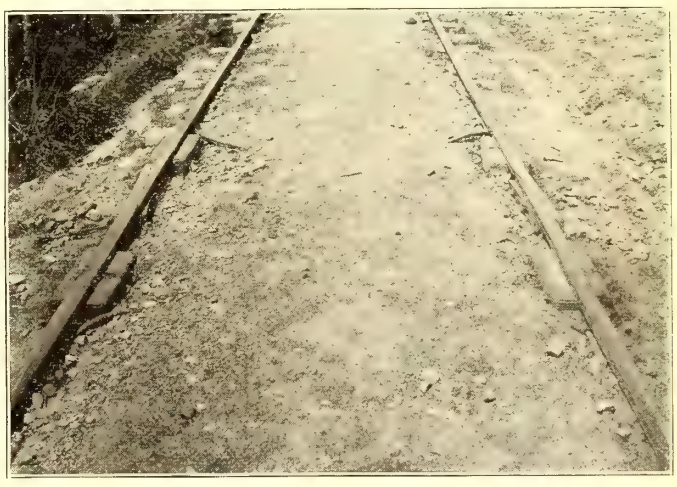
CURVE CONSTRUCTION WITH FIG. 8 TROLLEY WIRE

on broken stone or gravel ballast with Weber joints. The Weber joints have, so far, given entire satisfaction, and after a year of service the rail ends are firm in position, without the slightest depression.

The company makes its own special work, and its shops have turned out a number of extremely complicated pieces. The frogs and crossings are re-enforced by strips of hardened steel let into recesses and pinned in position. These can be easily replaced when worn out.

On the line to Wauwatosa, recently purchased from a company which formerly operated a dummy line upon it, is a fine and costly viaduct, crossing the valley of the Me-

CAST WELD STEEL JOINT IN EXPOSED TRACK



nominee River and the tracks of the Chicago, Milwaukee & St. Paul Railroad. Another viaduct, 1075 ft. in length, having between its termini a transition curve of approximately 125 ft. radius, is now being constructed between the grounds of the Calvary Cemetery and those of the Soldiers' Home, near the Menominee River viaduct. At about the center of the new viaduct will be an elevated station to be used by visitors to both the cemetery and the Soldiers' Home, and upon its completion it will be part of a new through line to Waukesha Beach, on which the time of transit from the center of the city will be considerably less than at present. By improvements of this kind the system is being greatly strengthened and the future traffic earning capacity increased.

The greatest attention is given to the maintenance of roadbed. Handcar inspection of all the high speed lines is made every morning, and necessary realignment, surfacing and improvement of joints and special work are at-

STEEL JACKETED, CAST WELD RAIL JOINTS IN CITY TRACK

tended to without the slightest delay. The city track is constantly under inspection by men employed for that purpose, who have, however, other work to do, such as

SPLIT JOINT IN EXPOSED TRACK

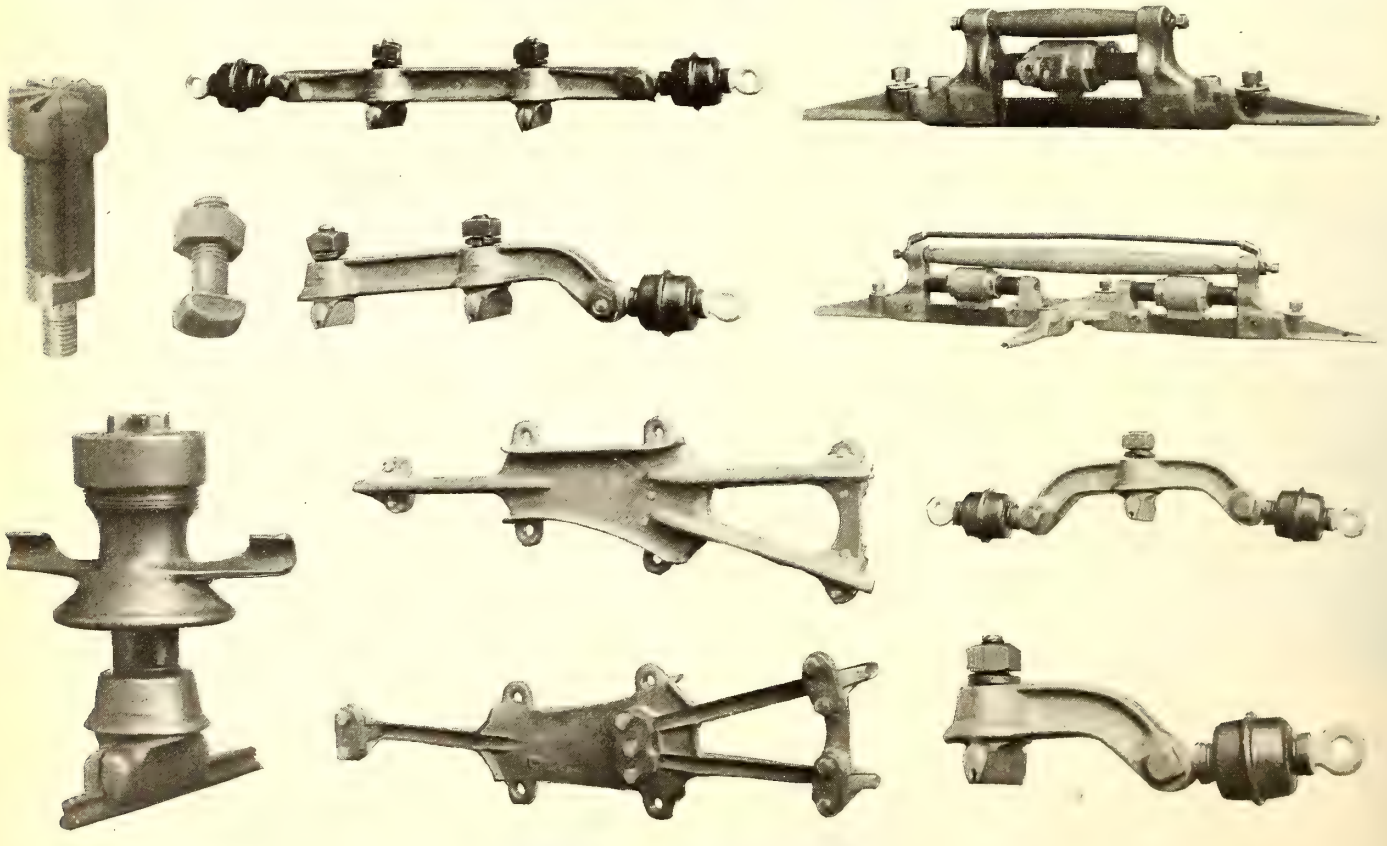
greasing curves, sanding the track, etc., and at least once a week the superintendent goes over all the interurban and most of the city lines in his "office car." The importance of this constant and rigid inspection may be judged from the fact that speeds of 45 miles per hour or more on certain portions of the interurban lines are of daily occurrence.

OVERHEAD AND UNDERGROUND CONSTRUCTION

During the last two years almost the entire mileage of overhead line work has been rebuilt with new and strong

material throughout. The 000 "Fig. 8 trolley wire" is the company's standard, and is giving absolute satisfaction in all respects, the report of its value being, indeed, quite enthusiastic. The chief disadvantages which have in other places been urged against this type of trolley wire, namely, the difficulty of supporting it satisfactorily, and of running

STANDARD CITY CARS



100 DUCT CONDUIT NEAR STATION

good curves, and the large section required, are not regarded as important by the Milwaukee management.

A special clip, devised by the company's engineers in conjunction with those of the Electrical Railway Equipment Company of Cincinnati, is used for supporting this Fig. 8 wire. It seems to have entirely overcome all obstacles to the use of this wire, and some of the finest curves and straight line work to be seen in any city (see page 341) are to be found in Milwaukee. A large section of trolley wire means, of course, the cheapest possible reinforcement of the feeder system, as there is no charge for insulation. The great advantage of the Fig. 8 wire is, of course, the doing away with sparking at the clips, by reason of the fact that a perfectly clear path for the trolley is obtained.

In other respects the company has taken great pains in developing a complete line of overhead appliances. These are manufactured by the Electric Railway Equipment Company. Anderson & Johns' insulation is the foundation for this material, and bronze is the metal employed. Illustrations of some of the special appliances used are shown herewith. They are solidly and well constructed, and so carefully have all details been designed that trouble from broken trolley wire is now very rarely experienced.

FORMS OF FIG. 8 LINE APPLIANCES

A large number of center poles are used, but are not liked by either the company or the public, and the span wire construction is preferred in all cases. Iron poles are used generally within the city limits, and wooden poles outside. Many of the iron poles are "lattice" construction, but the heavy tubular pole is preferred as being stronger, more durable and less costly to keep in good condition.

The overhead construction is carefully and regularly in-

STATION AT WEST PARK

spected for wear, broken span wires and defective insulation. For this purpose the repair and inspection car and the patrol wagon are used, shown on page 350, and are fitted up with all tools required for quick repairs.

The underground feeder system is installed in the business district of Milwaukee. Camp vitrified brick conduits are used, and recent purchases of feed wire have been made from the Standard Underground Cable Company

OFFICE BUILDING OVER LIGHTING STATION

STORES, YARDS, AND CONSTRUCTION FACILITIES

The company's plans for new construction have been, and are, so extensive that the construction work has been organized most carefully, and purchases of material and supplies made and arranged for on a large scale. The company owns a 10-acre gravel pit near Waukesha, from which all its grading material is obtained, and contracts have recently been closed with a large blast furnace near its yards by which the slag and other furnace refuse can be obtained in any desired quantity for surfacing of track. Ties, paving stone and other material are always on hand in quantity, and the company was fortunate in purchasing a large tonnage of rails and track material before the recent advance in prices.

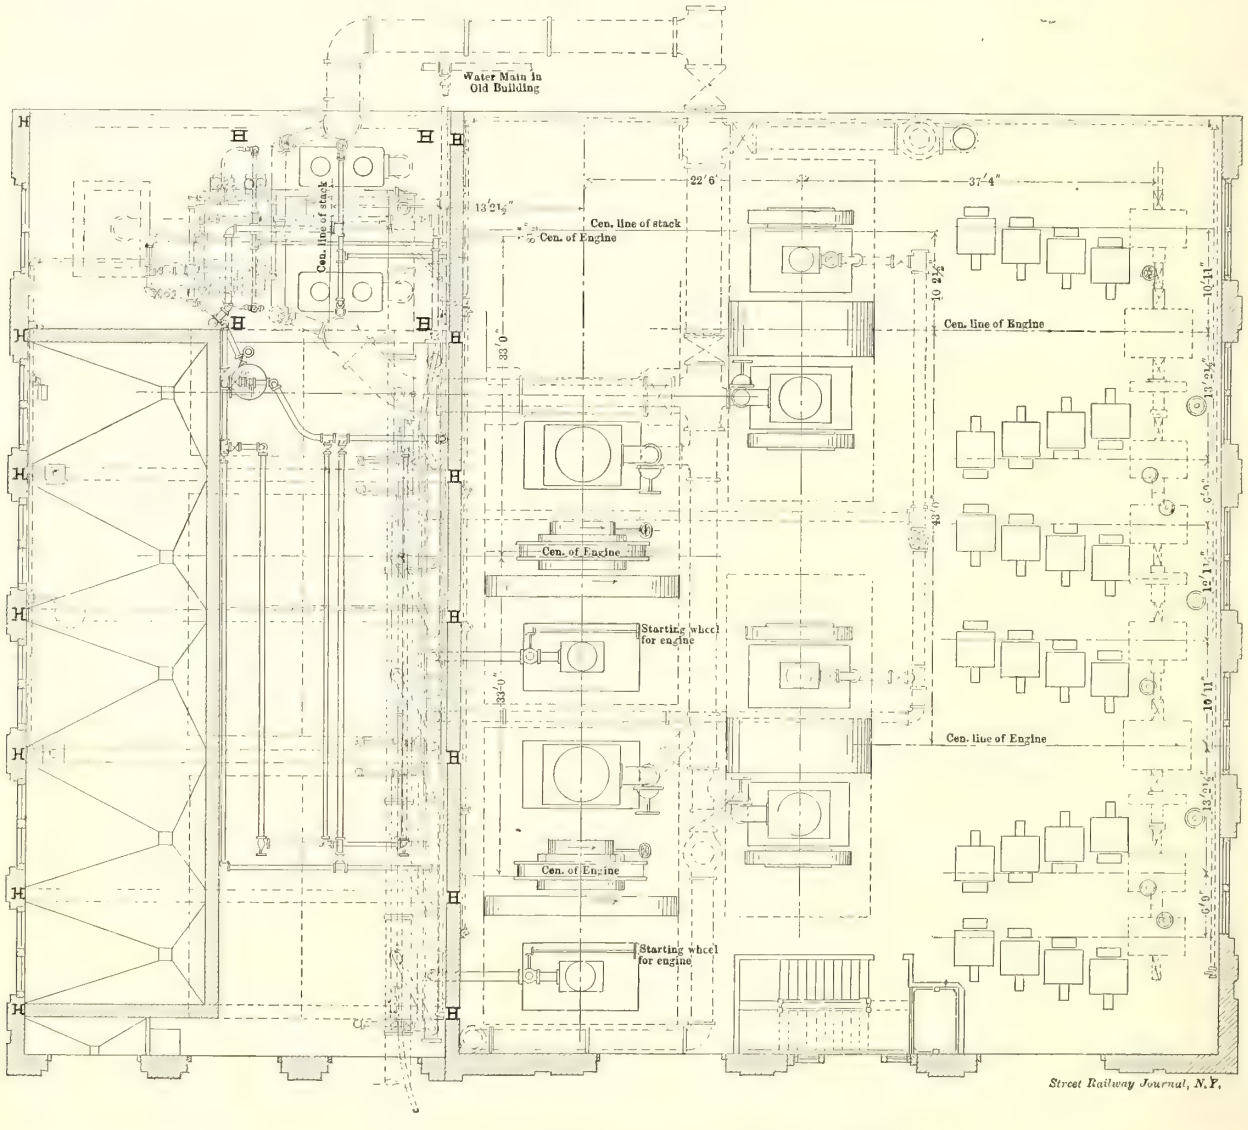
For the purpose of storing this construction material and facilitating its receipt by rail and water, the purchase of a 5-acre swamp abutting the tracks of the St. Paul and the Chicago & North Western railroads on one side and the Kinnickinnic River on the other was made some time ago, and has since been piled and filled in so as to form an extensive and very valuable piece of real estate. Arrangements have just been made by which the company's street railway tracks in the vicinity are connected with a loop line in this yard, and a branch from the St. Paul and North Western tracks also enters the yard.

Construction work is facilitated by a large equipment of work cars, which the company is permitted to use on the city tracks, as well as the interurban, and which, of course, greatly reduces the cost of transportation of material.

The company's storerooms at the Kinnickinnic car house, near its yards, are among the most extensive to be

WORK TRAIN ON GRAND AVENUE

found in any street railway system of the country. The inventories show that there are now on hand about $125,000 worth of "live" material and supplies, most of it purchased before the recent large advance in prices. The stores are most neatly and systematically arranged.



POWER STATIONS

The railway and lighting system is now being operated from seven power stations, large and small, two of which are merely held in reserve to provide for breakdowns elsewhere. It is probable that several of these stations will disappear as soon as the large new station now building is completed. Three-phase transmission will come into extensive use a little later. The main station, both old and new, is located on River Street, on the banks of the Milwaukee River, in the very heart of the city. Three stations, bought from other companies which are now consolidated with the present one, are found within the Milwaukee city limits. The fifth station is at Racine, the sixth at Waukesha, and the seventh at Wauwatosa. The relative capacities of these stations are as follows:

	Railway.	Lighting.
River Street station	2250 kw.	1120 kw.
Racine station	875	167
Waukesha station	600	...
Eleventh and Wells Street station (reserve)	400	...
Wauwatosa station (reserve)	130	150
Badger station	Approx.	1000
Broadway station	...	1115
Total capacity	4255 kw.	3552 kw.

The River Street station was built in 1891, and was one of the first large railway power stations in America. Its equipment is now out of date, though it is giving fair satisfaction, and the company is building a large new power station in the plot adjoining the present one, the intention being that after completion of the new station the old will be demolished and its place taken by an extension of the new.

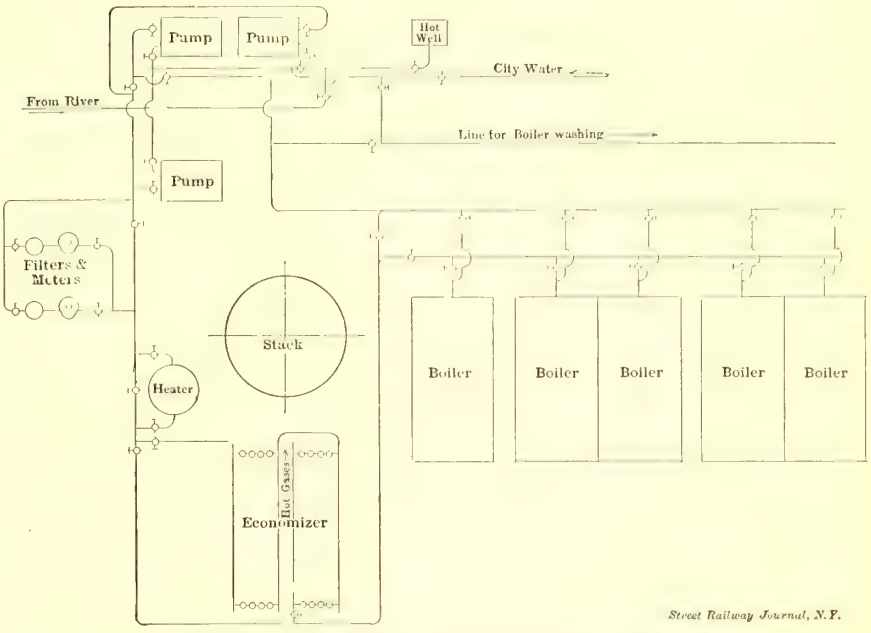
The present equipment in the old station consists of eighteen Galloway boilers, with coal and ash conveyors, made by Link Belt Engineering Company, and eight triple expansion marine type engines, of which five are each direct connected to two 200-kw. Edison multipolar railway generators, and three are connected each to two

PLAN OF NEW POWER STATION, SHOWING PIPING

100-kw. multipolar Edison three-wire lighting generators. These engines were designed by the Edison General Electric Company, and several of them were manufactured by Filer & Stowell Company, of Milwaukee. There is also in the station one Allis vertical compound engine, direct connected to two 200-kw. Edison lighting generators; one McIntosh & Seymour engine, belted to two 60-kw. Edison bipolar lighting generators; one triple expansion engine, direct connected to two 50-kw. Edison generators, which were formerly lighting machines, but have now been rewound for railway booster service; and one McIntosh & Seymour horizontal tandem compound engine, belted to one 150-kw. Edison bipolar railway generator. The Edison multipolar generators are all of the end-bearing commutator type, with side-bearing brushes, and the armatures serve as flywheels. They were originally somewhat too light in construction to stand the strains of railway service; but have been so altered as to be fairly satisfactory and efficient machines, and no serious electrical troubles have ever been developed in them. The present station cannot be called economical, however, as the cost of power production slightly exceeds one cent per kw. hour, of which about $.0066 is for fuel, and it is expected that the new River Street station will reduce this cost of production fully one-half.

The new station, of which plan and elevation is given herewith, will contain five Edgemoor water-tube boilers, with Green traveling chain grates; McCaslin coal conveying machinery; one Green economizer; two 1400-h.p. and two 1100-h.p. Allis engines; four 1050 and four 400-kw. General Electric generators; twenty 100-light Brush arc machines, and the usual steam and electric auxiliary apparatus.

The furnaces will be fed from large hoppers, located near the top of the boilers, and which are filled in turn from bunkers of from 1500 to 2000 tons capacity, supported on strong iron pillars above the boilers. The conveying apparatus will be used in combination with steam shovels for filling these bunkers from boats or cars, and will also handle the ashes. The conveyors are of the McCaslin overlapping gravity bucket conveyor type, and are manufactured by John A. Mead & Co., of New York. They handle both coal and ashes, and the buckets overlap, so that no filler is required except an ordinary chute.

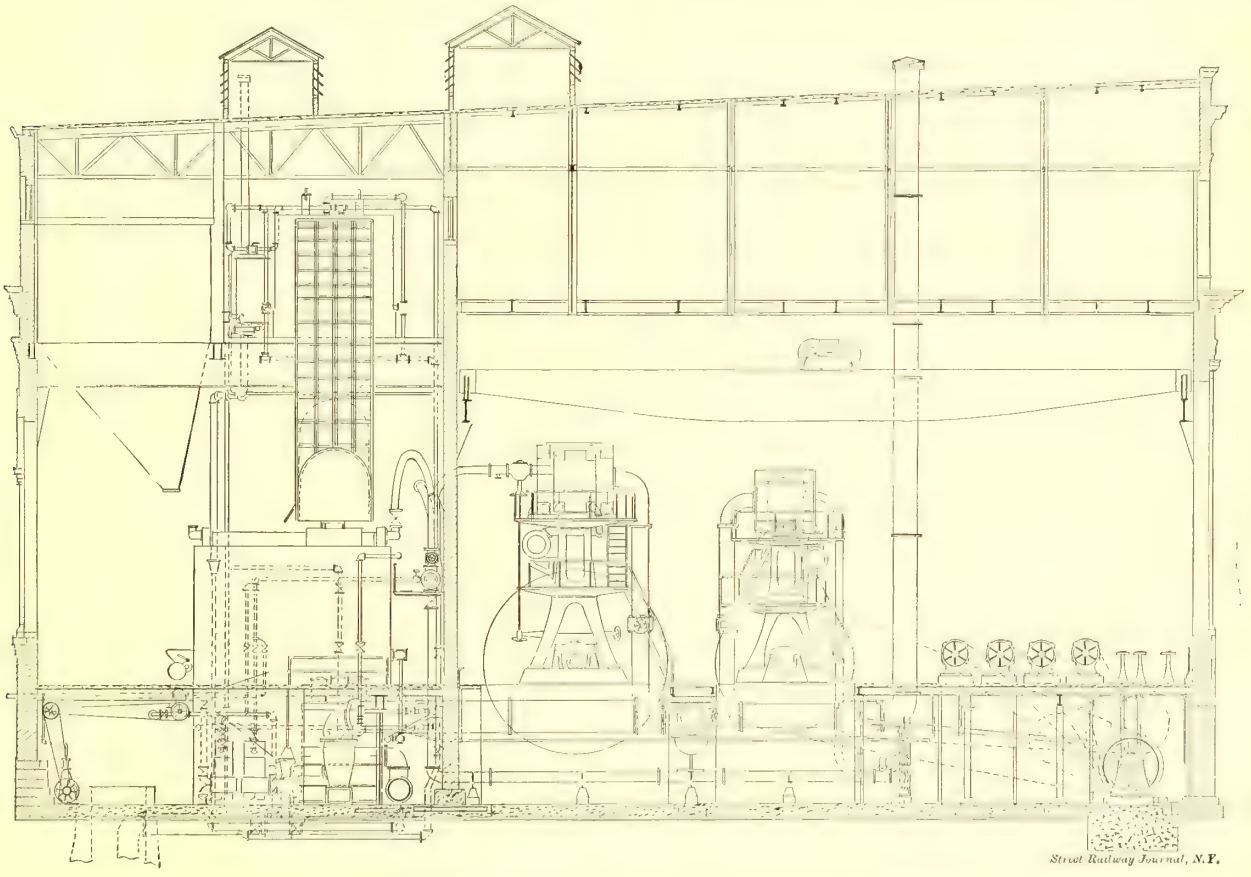


Both buckets and links are of malleable iron. The coal will pass from the bunkers, through the hoppers, direct to the traveling chain grates. These are made by the Green Engineering Company, of Chicago, and it is guaranteed that the grates will burn from 18 lbs. to 36 lbs. of coal per sq. ft., and will prevent the formation of smoke.

The boilers, made by the Edgemoor Iron Works, of Edgemoor, Del., have each 233 18-ft. lap-welded tubes, 4 ins. in diameter, and three 34½-in. drums. They are to carry 160 lbs. steam pressure, and are guaranteed to evaporate 10½ lbs. of water from and at 212 degs. with less than 2 per cent moisture under ordinary conditions of running, when coal having not less than 13,000 B. T. U. is used, with ¾-in. (water column) draft, and when boiler is operated at not less than 750 h.p. Centennial standard. The guarantee also covers 11 lbs. under proper test conditions. The total capacity of the five boilers working together is guaranteed to be not less than 4100 h.p., Centennial standard. The Green Engineering Company, of Chicago, will install the boilers.

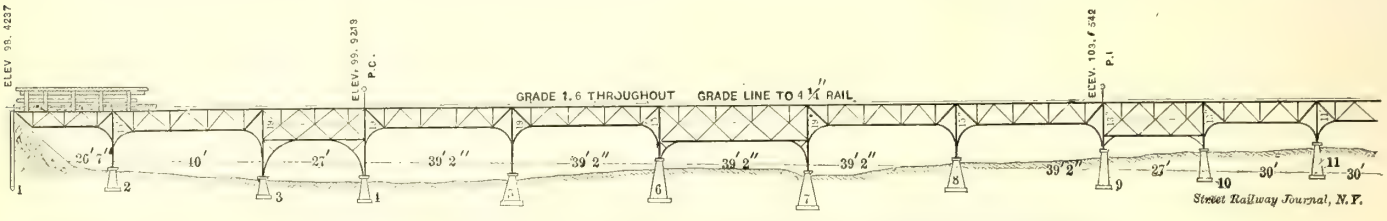
The Green economizer is composed of 768 tubes, in 128 sections, ranged in four groups of 32 sections each. Each section contains six tubes, 9 ft. long and 4 9-16 ins. in external diameter. These tubes are connected top and bottom to headers. The scrapers are to be operated by a 220-volt 4-h.p. electric motor. It is guaranteed that the average fuel burned shall be 12 per cent less when the feed water from the hot well is put through the economizer than when the economizer is not used, it being understood that the boilers are running at full-rated capacity.

The stack is of steel, brick lined, and will be about 200 ft. high and 16 ft. internal diameter in the clear. Its capacity is about 22,000 to 25,000 h.p.



There are two duplex vertical Blake pumps, of the standard Admiralty type, and two Blake condensers of the same size and type as those used on the Kaiser Wilhelm der Grosse.

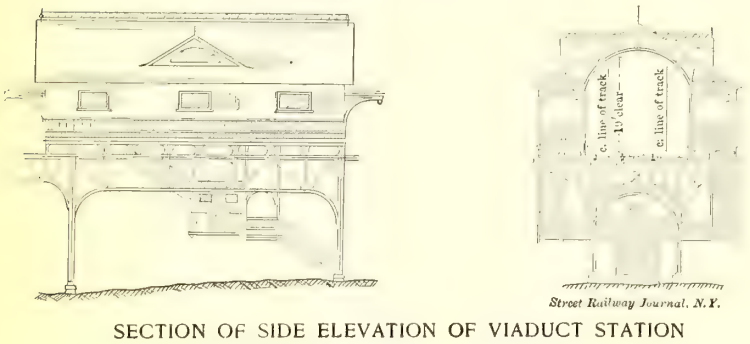
GENERAL DIAGRAM OF FEED-WATER SYSTEM



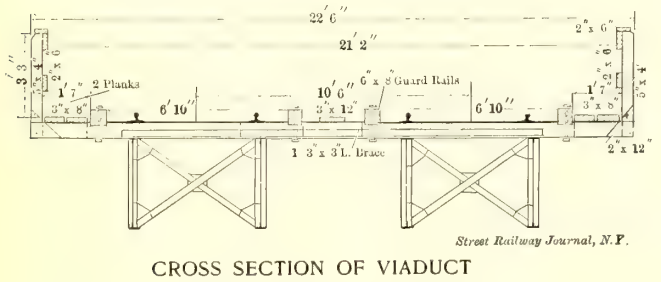
In the engine room is a 30-ton 80-ft. span electric crane, with three motors, built by Pawling & Harnischfeger, of Milwaukee.

Both railway and lighting engines are built by the E. P. Allis Company, of Milwaukee, and are of the cross-com-

CROSS SECTION OF NEW POWER STATION



pound vertical type, with Reynolds-Corliss valve gearing. The railway engines have cylinders 28 ins. and 60 ins. x 48 ins., and are guaranteed to indicate 1400 h.p. at the point of highest steam economy, and 2400 h.p. at maximum load, with a boiler pressure of 150 lbs. and a vacuum of 26 ins. These engines run at 80 r.p.m., and it is guaranteed that the regulation shall be such that the minimum



PORTION OF DOUBLE TRACK VIADUCT—CALVARY CEMETERY EXTENSION

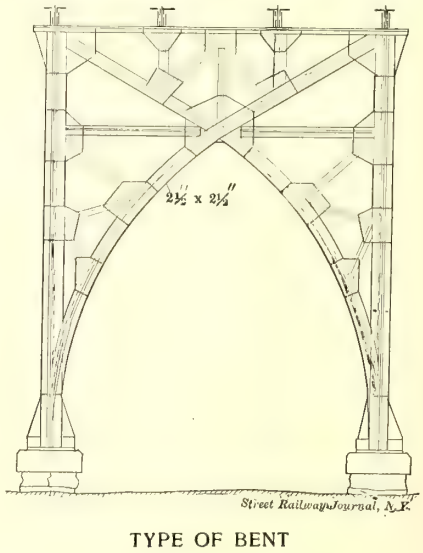
speed shall not be less than 79 revolutions and the maximum 83. The flywheel is 20 ft. in diameter, and weighs 120,000 lbs. The cylinders are not steam jacketed, but the receiver is equipped with reheating coils fed by live steam. The valves are placed in the cylinder head, by which arrangement the clearance is reduced to about 1½ per cent on the low pressure cylinder, and nearly that on the high. It is guaranteed that when running under uniform load of 1400 i.h.p., with 150 lbs. pressure at the throttle, with 26-in. vacuum in exhaust pipe, and at 80 r.p.m., the engines will consume but 13½ lbs. of dry steam per i.h.p.

The lighting engines will run at 120 r.p.m., will indicate

SECTION OF SIDE ELEVATION OF VIADUCT STATION

CROSS SECTION OF VIADUCT

1100 h.p. at highest economy and 1600 h.p. maximum, and the speed will not be below 118 nor more than 123 r.p.m. with any variation of load. The cylinders are 22 ins. and 46 ins. x 42 ins., and the flywheel is 15 ft. in diameter, weighs 35 tons, and has a face 60 ins. wide, grooved for rope driving. An economy of 13½ lbs. is also guaranteed for the lighting engines under conditions similar to those just stated.

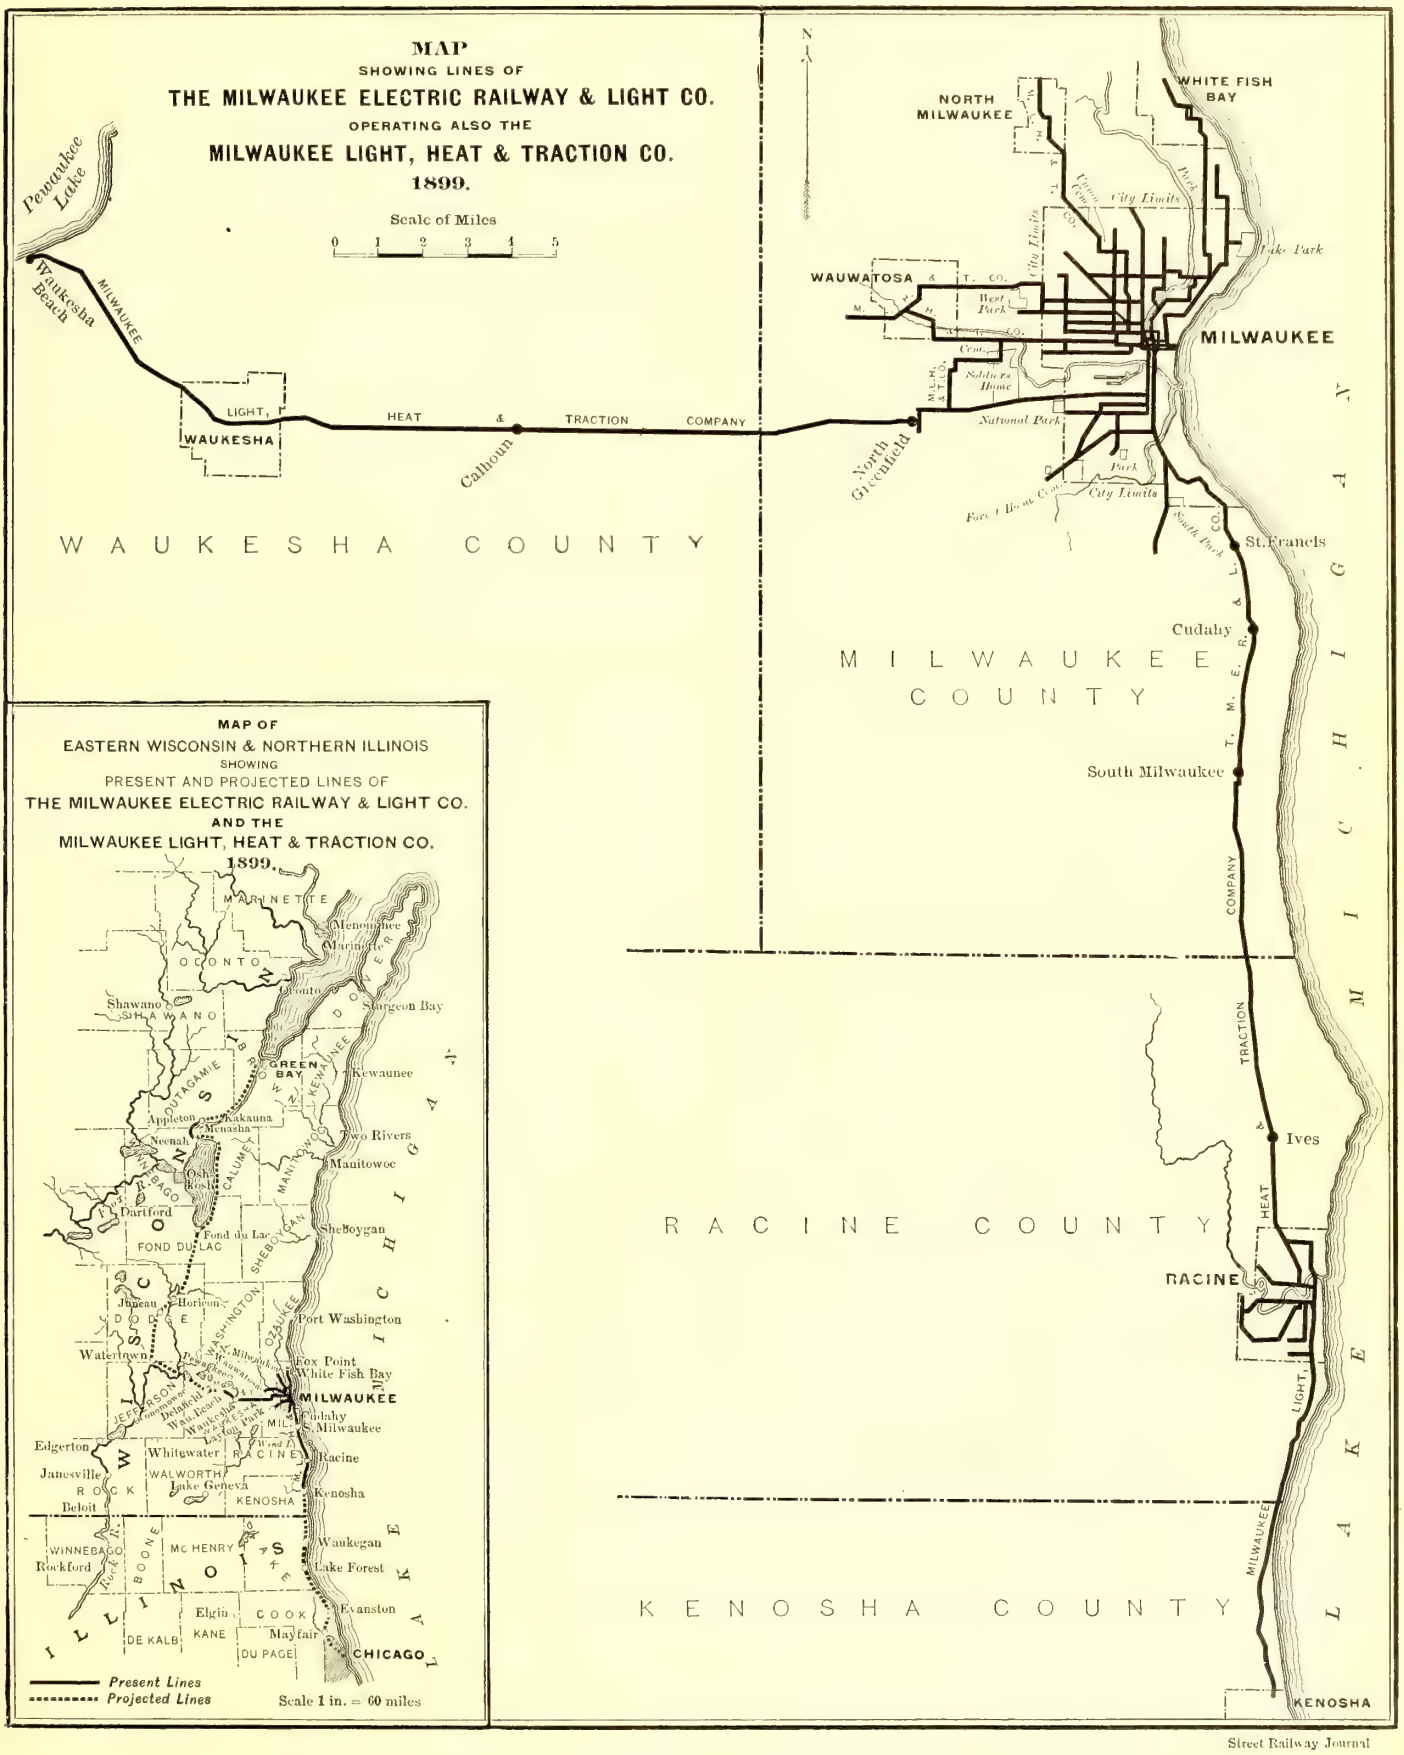


The railway generators, built by the General Electric Company, are of their "M.P.14" type; are rated at 1050 kw. or 1755 amps. at from 500 to 575 volts, and are direct connected to their engines. It is guaranteed by the makers that after ten hours' run at normal full load the temperature rise will not exceed 40 degs. C., and that after one hour run at a load 50 per cent above the normal full load, immediately following the ten-hour run at normal load, the temperature shall not exceed 50 degs. C. above the surrounding air. It is also guaranteed that a load 50 per cent above the normal can be carried without sparking at, or moving of, the brushes. The commercial efficiency at full load is to be 95 per cent, and at half load 94 per cent.

The twenty 100-light Brush arc machines, built by the General Electric Company, which are to be installed in this station form part of an order for sixty of the same type given by Mr. Beggs for use in Cincinnati and Milwaukee, this being the largest single order for arc light machines ever placed. The arrangement of these generators and of the counter shafting and rope drives by which they are run is clearly shown in the plan and cross sectional views herewith.

There will be in the station an immense marble switchboard built by the General Electric Company, arranged for forty-eight arc light circuits and forty-eight machines, and for all other railway and lighting circuits.

CAR HOUSES AND OTHER BUILDINGS



The company owns a number of car houses, located at various points upon the line, and an office building directly over one of the lighting stations recently purchased. For the purpose of facilitating car movement, especially at

TYPE OF BENT

times of sudden rain or snow storms, when the patrons are driven quickly to the cars, an option has been secured on a valuable piece of ground, 320 ft. x 240 ft., in the heart of the city, on which it is proposed to put up a building which will have a variety of uses. The ground floor will be the loop line terminal for practically all the east and west lines of the city, and three floors will be given up to car storage, with special means for quickly putting cars into service below. The company's offices will also be in this building, and there will be ample space devoted to the uses of the employees, in the way of gymnasia, library, reading rooms, meeting rooms, instruction rooms, etc.

The principal shop, the Kinnickinnic car house, is fitted up for the performance of all necessary repairs of rolling stock and power station equipment. Here also are to be found the foundry and the shops for the manufacture of

Street Railway Journal

MAP SHOWING ELECTRIC RAILWAY SYSTEM OF THE MILWAUKEE ELECTRIC RAILWAY AND LIGHT CO.

special work, as well as the storerooms, while, as before-stated, the large construction yards belonging to the company are close by, crossing the tracks of the two large railroads entering Milwaukee.

CAR EQUIPMENT

The standard cars of the Milwaukee Electric Railway & Light Company in its city service, and of the Milwaukee Heat, Light & Traction Company in the suburban and interurban service are so unusually sightly, comfortable and attractive to the riding population that a somewhat extended description of their characteristics is well worth while. The color scheme is nearly the same as the Broadway Metropolitan cars in New York—colors which always give a bright appearance to the cars in the streets. Inside, the finish and trimmings throughout are in quartered oak, and cane-bottomed cross-seats with center aisles—a seating plan always popular with the public—are combined with large windows, so that an excellent combination summer and winter car is obtained. The car interior finished in this way, without elaborate over-ornamentation, has a particularly *clean* look, and the whole aspect is decidedly pleasing.

The double-truck interurban cars of this general type were built by the Barney & Smith Company, of Dayton, and the St. Louis Car Company. The length over corner posts is 29 ft., and over bumpers is 41 ft. The width over all is 8 ft. 5 ins. The height from top of rail to bottom of sill, loaded, is 2 ft. 6 ins., and the inside height from floor to roof is 8 ft. 2 ins. The center and main side sills are of heart Southern pine, and a ½-in. iron plate, 5 ins. wide, furnishes additional strength to the side sills. The end sills and all cross and trap-door framing are of white oak, and posts, rails, rafters, etc., are of straight-grained white ash.

There are eighteen reversible and four stationary seats

PARLOR CAR

in the car, all made by the Hale & Kilburn Manufacturing Company, of Philadelphia. The curtains are made by the E. T. Burrowes Company. The car trimmings are of solid bronze, and folding iron gates are used on platforms. Electric push buttons summon the conductor.

The International double register is the company's standard, and is believed by the management to be the simplest and most durable in the market. The city cars are heated in the winter by coal stoves, and the interurban cars have the Baker hot water heater. In these long interurban runs it is not considered wise to run the risk of losing power and freezing passengers.

The cars are lighted by four two-light clusters and two platform lights, with a switch for an electric headlight.

INTERIOR OF OFFICE CAR

On the long-run interurban cars electric arc headlights are used. These have done much to reduce night accidents, and are considered by the management to be one of the most important equipment features of the modern interurban road, in spite of their wastefulness in the use of current. These headlights take about 5 amps. of current, and over 80 per cent of the power must be used in the dead resistances, but it is believed that power is the cheapest thing found in electric railroading, while accidents are among the dearest from every point of view. The arc headlight is really a searchlight, and by its use the track and road are lighted up for about a quarter of a mile in advance of the car, making accidents as rare as in daytime.

In addition to the Barney & Smith and St. Louis cars, which are, as above stated, the company's standard at present, we find also in service twenty Brill cars on the National Avenue line and a large number of short cars of different makes, some of which have been, and are being, rebuilt for continued service, but most of which will be replaced by new purchases in the near future.

There is no question in the opinion of the management as to the great advantage of double-truck over single-truck cars in both city and interurban service. They are held to be easier on track and more attractive to passengers, and while taking more power to operate, it is not believed that the cost of power per passenger carried is greater, while the transportation cost is, of course, reduced. Moreover, by means of these cars a longer headway can be maintained without public dissatisfaction, for overcrowding is less likely to occur.

After a series of elaborate and most carefully conducted

tests, it has been decided to equip these cars, both city and interurban, with four G. E. 1000 motors as a standard. The advantages of this equipment lie chiefly in the greater traction obtainable and the much more rapid acceleration, by which means higher schedules of speed are possible. The tests have shown that the power consumption in such an equipment is less than where two motors of equal or greater aggregate power are used, and experience has shown that repairs of the four-motor equipment are less than of the two-motor, in spite of the duplication of apparatus. This is a surprising and very interesting result, but certainly appears to be borne out by the repair figures for 1898, which show an expenditure of only $.0038 per car mile for repairs of electrical equipment—an extremely low figure.

Recent purchases of trucks have been of the Barney & Smith "H" type and the St. Louis Car Company's trucks, but no permanent standards have been established. The wheels are furnished by the Terre Haute Car Wheel Company, are 33 ins. in diameter, weigh about 385 lbs. each, and are guaranteed for about 40,000 miles of serviceable running, which guarantee has been maintained. The axles are of hammered iron, 4 ins. in diameter.

The Waukesha and Wauwatosa interurban cars are equipped with the Christensen automatic air brakes, with

SPECIAL EXCURSION CAR

independent motor compressor, and the highest satisfaction has been expressed by the management at the work of these air brakes, which are considered essential in the high-speed interurban work, of which there is so much around Milwaukee.

A number of parlor cars, nicely fitted up for excursions, are in service, and one car, "Marguerite," is especially ornate, being lined on the outside with incandescent lamps, and lending itself well to decoration. The superintendent has fitted up a special office car, with which inspection of the lines is, as before stated, carried on regularly, while, at the same time, considerable office work can be accomplished by means of the stenographer and typewriter who accompanies him on his trip.

There are several emergency and patrol wagons located at several points in the city. These wagons are kept ready for immediate call in exactly the same way as is done by the fire department, harnesses being suspended in such a manner that the horses can be immediately put into position and the wagons run out of the house with but a few seconds delay. On a recent inspection trip a patrol wagon was called by telephone at a point one-half a mile away from its house, and it arrived on the ground in less than 2¼ minutes after telephone connection was made.

For the purpose of providing against blockades from breakdowns on the road each motorman is given a toolbox, which is numbered with his badge, and for which he is responsible. This box is equipped with all the tools necessary for above repairs on the road. While it is not the company's purpose to allow the motormen to do anything except emergency work on the cars, they are given

STANDARD INTERURBAN CAR

a training sufficient, it is believed, to enable them to get their cars into the station under ordinary conditions.

The construction cars have already been referred to, and an illustration of one is given on the following page.

The snow equipment is somewhat extensive, and is strong enough to grapple with any storms which may visit Milwaukee; in fact, there have been some fine records made in dealing with heavy storms which have blocked railroad travel while the electric cars have been able to run.

It is found from the company's books that the entire cost of maintaining the rolling stock in 1898 was $.0091 per car mile, of which $.0022 was expended for car bodies, $.0017 on trucks, $.0038 on electrical equipments, and

INTERIOR OF STANDARD CAR

$.0014 on superintendence, tools and miscellaneous expenditures. These are extremely low figures, in spite of the fact that the rolling stock has been kept up in first-class condition without the slightest depreciation.

CAR SERVICE

The average speed schedules of the city of Milwaukee are somewhat high, being from 8 to 9 miles per hour on an average, while on the suburban and interurban lines

PATROL WAGON

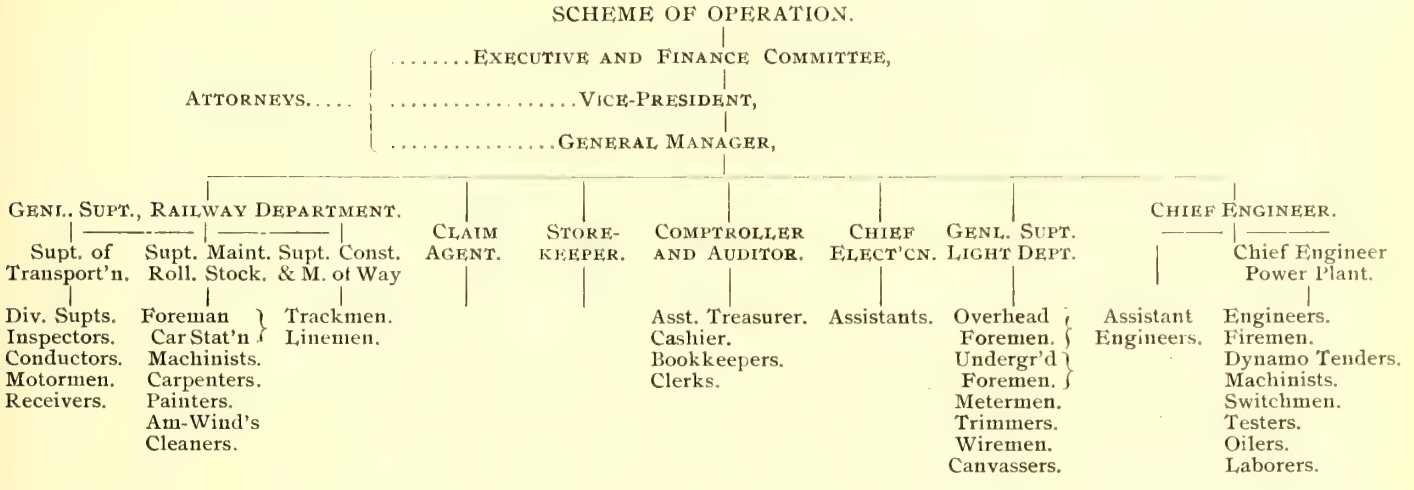
they are 20 miles per hour. The run from the center of Milwaukee to Waukesha, a distance of 20 miles, is regularly made in fifty-five minutes, and has been made in forty-five minutes. These are high figures in view of the fact that several miles of the distance lie in the city proper, with considerable local traffic, while there are numerous curves and detours on the line which have not yet been gotten rid of. Two Waukesha cars regularly make nineteen half-trips a day, or 380 miles each, this being one of the highest electric car day records to be found in this country.

The greatest care and attention is given to the securing of punctuality in the operation of the entire system. Each of the lines, city as well as suburban, has several time points, and the motorman is called strictly to account if he falls more than a minute behind time at any of these points. Results have shown to the management that this element of punctuality is most important in obtaining traffic, and goes far to offset a slight increase in the time interval between cars, since it is less important for the would-be rider to get a car at the moment he steps upon the street than it is to know that if he steps upon the street at a particular moment he will get his car. Largely owing to an increase in speed, gradually brought about in the last two years, the present management has succeeded in giving a superior service to the public with a less number of car trips and car miles, so that the earnings per car mile have been materially increased without a corresponding increase in expenses, and this is one of the potent causes for the large financial improvement in the properties.

An hourly service is maintained between Milwaukee and Waukesha, Whitefish Bay and Racine-Kenosha; a half-hourly between Milwaukee and South Milwaukee; and a fifteen-minute alternate service on two lines between Milwaukee and Wauwatosa. In the city the cars are run on a time interval of from six to ten minutes.

There is on this system a most complete private telephone system, and all of the dispatching business on the interurban lines is conducted by telephone. At the present time more than fifty points on the system are connected with the central office by telephone, and the number will be largely increased in the near future. On arriving at switches, or other meeting points, instructions are sought for and received by each conductor over the telephone, and a notation of the call and of the instructions given is made on a large sheet in the dispatcher's office, where also is made a record of every kind of trouble reported on the system, including accidents (even of the most trivial character), breakdowns, failures to make time, etc. This feature of operation is to be still further improved and extended in the near future, but is already efficient and satisfactory.

The company has regularly in its service a surgeon, whose duty is to drive immediately upon call to any point in the system where an accident may have occurred, and to render every assistance in his power to the injured person. This course is dictated not only by humanity, but by wise economy, since it is almost always possible to obtain a truthful statement of the accident immediately after its occurrence, while after several days' delay garbled or deceptive accounts are not infrequent. As a matter of fact, the company's disbursements for injury are small, in spite of the high speeds maintained by the cars, the regular fund, amounting to 3 per cent of the gross earnings, which has been set aside for the past two or three years, proving so far sufficient to take care of all disbursements on this account.



RACINE-KENOSHA CAR

INSPECTION AND REPAIR CAR

ORGANIZATION

The company's scheme of organization is clearly shown in the accompanying diagram.

The executive and finance committee consists of Charles W. Wetmore, chairman; William Nelson Cromwell, of the law firm of Sullivan & Cromwell, and George R. Sheldon, all of New York.

Henry C. Payne, the company's vice-president, has been connected with the property ever since the original purchase of the constituent companies by Henry Villard and the North American Company in 1891-2. He is one of the ablest and most influential men in the State of Wisconsin, and his influence and assistance have been of inestimable value to the company. Mr. Payne was president of the American Street Railway Association in 1893-4.

The responsible executive head of the company is its general manager, John I. Beggs, to whose skillful and aggressive work the great improvement in the physical and financial condition of the property during the last three years is largely due. Mr. Beggs' reputation as a successful manager of corporate enterprises, particularly in the field of electric lighting and the manufacturing of electric apparatus, is established by numerous successes and no failures during the past twenty years; but it was reserved for Milwaukee to prove that in the larger field of electric railroading even greater success would be achieved. His policy is broad and far reaching, as has been indicated at several points in the previous discussion, and it is not too much to say that one of the most valuable lighting and railway properties in the West is now being developed by him, and will eventually reach proportions far larger than at present.

The comptroller and auditor, H. C. Mackay, is in charge of the accounting department. The company's accounting system closely follows the standard of the Street Railway Accountants' Association of America, although greater detail in many of the accounts is required by the general manager. Owing to the rapid development of the system, and especially to the recent purchases of important interurban lines, the accounting system in its details is still in a formative condition.

The general superintendent of the railway department, T. E. Mitten, has been with the company for five years, and is in direct charge, under General Manager Beggs, of the operation of the railway lines.

The chief engineer, Chester P. Wilson, was formerly general manager of the Sioux City Traction Company.

The company's chief electrician is O. M. Rau, who is now acting as general superintendent of the light department.

In the month of April there were 1673 employees on the company's payrolls, of whom 84 were in the general office, 709 in the transportation department, 305 in the maintenance departments, 106 in the power stations, 83 in the lighting department, and 386 in the construction department.

FINANCIAL RESULTS

It has before been stated that remarkable changes have been made during the three years of the present management in the financial and operating statistics of the Milwaukee property. The real character of these changes can best be seen by an examination of the comparative statistics of operation expressed in "per car mile" and "per passenger" figures. The following results are for the railway department of the Milwaukee Electric Railway & Light Company only, it being impossible to obtain a similar comparison for the Milwaukee Light, Heat & Traction Company on account of the recent purchases of its most important properties:

GENERAL FINANCIAL STATEMENT.

	per car mile.

OPERATING EXPENSES IN DETAIL.

	per car mile.		
	1896.	1897.	1898.
General expense	$.0136	$.0164	$.0199
Conducting transportation	.0724	.0673	0702
Maintenance, way and structures	.0064	.0116	0116
Maintenance, rolling stock	.0123	.0110	.0091
Total	$.1047	$.1063	$.1108

	per cent to total op. ex.		
	1896.	1897.	1898.
General expenses	13.00	15.42	17.91
Conducting transportation	69.10	63.26	63.41
Maintenance, way and structures	16.10	10.94	10.46
Maintenance, rolling stock	11.80	10.38	8.22

The most remarkable feature of the above statement is found in the 33 per cent increase in total receipts per car mile, and in the fact that the earnings from operation per car mile have been nearly doubled in the three-year period. Surplus for stock is affected largely by the amount set aside for "reserves and taxes," and as the company's practice in this respect is remarkably conservative and most admirable in conception, an explanation of the meaning of "reserves" is in order.

DEPRECIATION AND OTHER RESERVES

For the first six or seven years of operation depreciation in operating expenses was overlooked and neglected in the scheme of finance, and nothing was set aside to take care of the "deferred operation expenses," which come when track and equipment are worn out, and large sums of money have to be put into the property in order to replace them. In many cases in American street railway practice the investment or capital account has to furnish these sums of money, which are, nevertheless, operating expenses pure and simple, and a measure of the "depreciation" which has taken place during the previous operating period. European practice is, on the contrary, very rigid in requiring all railway and manufacturing companies to take from their operating expenses every year a certain amount to cover depreciation before declaring dividends to stockholders.

Two or three years ago the Milwaukee company awoke to the realization of the mistake which had been made in not providing a reserve fund for depreciation, and it was decided to immediately reorganize the finances on a far more conservative basis. The plan adopted was as follows:

Fifteen thousand dollars is set aside each month as a reserve fund for depreciation of railway plant, and $2,000 for depreciation of lighting plant. At the same time 3 per cent of the gross earnings of the railway and 1 per cent of the gross earnings of the lighting departments are set into a reserve fund to provide for injuries and damages arising in the operation of the property. In an "insurance fund" is placed an amount large enough to provide not only for actual disbursements in insurance premiums, but also for a surplus which it is intended shall take care of the uninsured losses from fire. A certain percentage of the gross earnings is also set aside for legal expenses, and, finally, $10,000 per month is passed into the fund for amortization of franchises, which expire about twenty-five years hence. The theory of this last item is that in case the company's franchises are not renewed at their expiration there is likely to be realized a large loss of capital, unless such a fund as this be provided in order that the investors may receive their principal, dollar for dollar.

All of these moneys taken out of the earnings in the way above stated are credited on the books to their respective ledger accounts, and are actually represented in the cash, bank, or otherwise liquid assets of the company. The sum of these accounts appears in the general statement in the item of "reserve and taxes" as in the above tables, and is a direct deduction from "earnings from operation."

If, now, it becomes necessary to replace twenty-five worn out cars, or to rebuild 5 or 10 miles of worn out track, the money for this is taken out of the bank, cash, or liquid accounts, and is charged directly to the reserve fund for depreciation. Small renewal expenditures arising in the current operation of the property and not involving the actual purchase of new rolling stock or bulk material, are charged directly to operating expenses as a current disbursement, and not to this reserve fund. Insurance and general expenses paid out are, however, charged to their respective funds, as these funds are established, not only for the purpose of gradually accumulating a reserve, but also as a bookkeeping method for pro rating the annual disbursement for these accounts evenly upon the twelve monthly statements. Taxes are dealt with in a similar manner and as an "accrued" obligation.

It is not intended that the depreciation fund shall ever contain large sums of money, but, on the contrary, most of the money is actually expended each year in the purchase of new rolling stock and replacement of track. Such a fund, however, has the effect of evening up expenditures over a series of years and taking out of the earnings that proportion which ought to be given over to maintaining the property in good condition, so that its actual value shall be always equal to its book value.

In the light of this discussion the following final figures will be interesting as a gauge of the financial results of the Milwaukee property during the past three years.

	per cent op. ex. to gross receipts.		
	1896.	1897.	1898.
Per cent op. ex. (actual disbursements) to gross receipts	67.7	57.2	53.4
Per cent op. ex., reserves and taxes, to gross receipts	87.7	71.0	76.4

The figures heretofore given appertain, as stated, to the street railway department only of the Milwaukee Electric Railway & Light Company. Its lighting department is, however, by no means unimportant, but in proportion to the investment therein contributes largely to the net revenues of the company. The surplus left for stock after paying the operating expenses, reserves and taxes, and the interest on its own investment, amounted in 1898 to nearly 40 per cent of the company's total surplus for stock. It is not probable, however that this high percentage can be long maintained for the railway earnings, gross and net, will doubtless increase far more rapidly than the lighting.

All in all, this great Milwaukee system has had the benefit of an operating and financial management of the most admirable character—a management which, if continued, can hardly fail to give it rank among the most substantial and valuable street railway properties in the world.

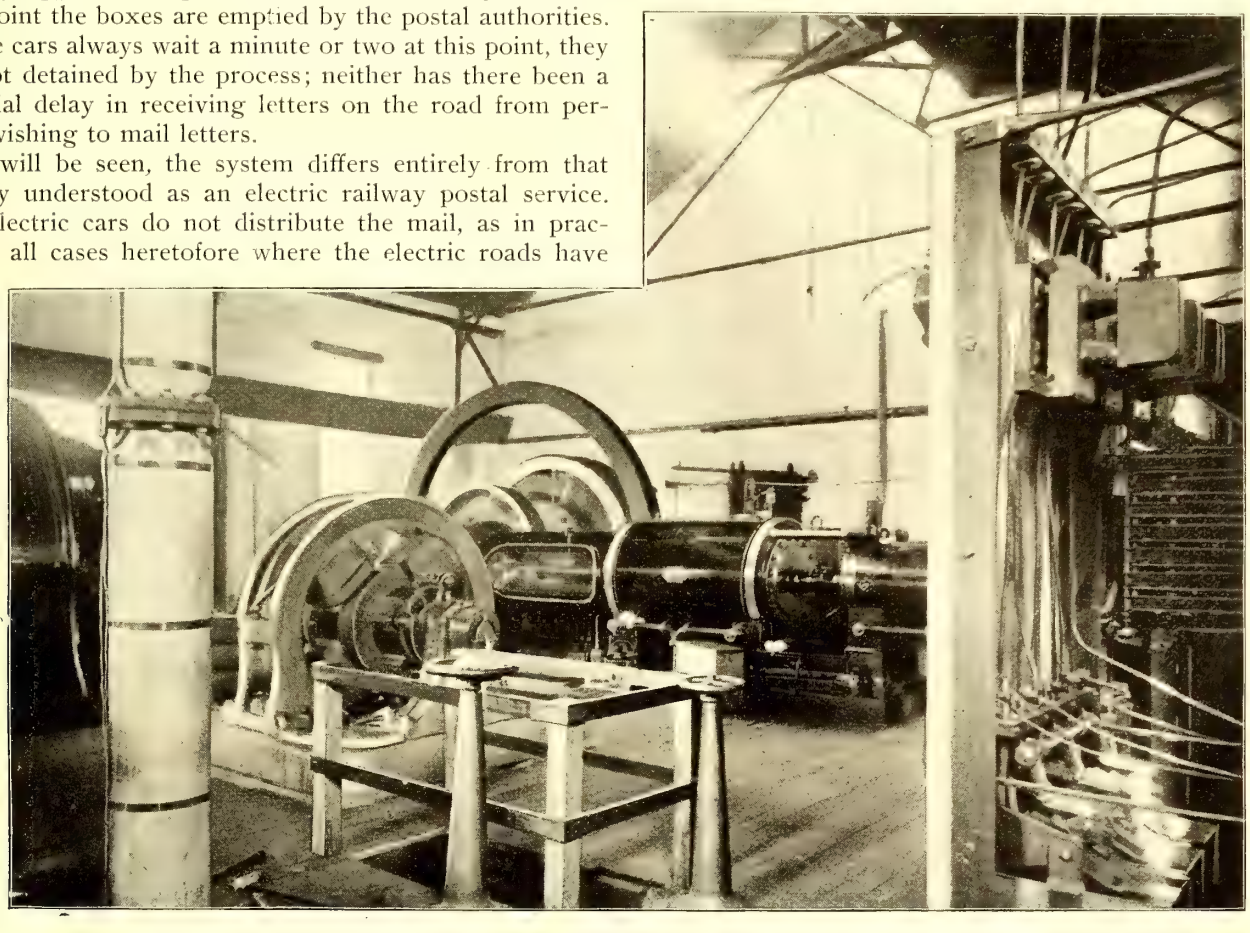
Accident Cases in Australia

The following is clipped from the legal department of the "West Australian" of March 17, 1899, and shows how railroad accident cases are treated in that country, where, it would seem, it is a serious offense for a man to get in the way of a locomotive:

Infraction of Railway By-Law.—Thomas Hodgins was charged with driving a horse and buggy across the railway when a train was approaching. Mr. Purkiss appeared for the Railway Department, and defendant was undefended. An engine driver said that defendant drove across the line in front of a train, the engine of which witness was driving, on the 1st inst. The engine struck the hind wheel of defendant's buggy and capsized and smashed it. The horse broke away, and defendant, unhurt, got up and ran after it, but the horse got into a cattle pit. When spoken to by witness, defendant admitted having tried to get across, as he thought he had time to get over, and his horse shied. Defendant said that he was driving an unruly horse at the time, and was afraid he could not pull him in, and that he would run into the train. He thought the only chance he had of saving his own life and that of the horse was to try and get across the line. He tried at first to pull the horse up. He got nearly across, when the engine struck the back wheels and defendant was thrown 10 ft. He was cut and shaken, but got up to try and catch the horse, which ran into a cattle pit and got its sinews cut. He considered the crossing dangerous. Defendant was fined 20s. and costs, in default one month's imprisonment with hard labor.

Letter Boxes on Cars

An interesting experiment is now being tried by the Hartford Street Railway Company, of equipping a number of its electric cars with ordinary drop boxes for the receipt of letters. These boxes are attached to one side of the rear vestibule of the car, so that they are protected from collision with passing vehicles or other accident. The public is invited to use these letter boxes for depositing their mail, and no charge is made by the railway company to the government for carrying these letters. All the cars of the company start from the center of the city, which is directly opposite the post office, and when they arrive at that point the boxes are emptied by the postal authorities. As the cars always wait a minute or two at this point, they are not detained by the process; neither has there been a material delay in receiving letters on the road from persons wishing to mail letters.



As will be seen, the system differs entirely from that usually understood as an electric railway postal service. The electric cars do not distribute the mail, as in practically all cases heretofore where the electric roads have acted in connection with the postal service, but assist in collecting the mail. The advantage to the railway company is principally in offering a convenience to the public, especially to its patrons, and the manager of the company, N. McD. Crawford, reports that so far there has been no drawback to the plan.

The system has proved most popular in Hartford, and has been well patronized. It was put in operation on a half-hourly schedule on April 1, when it was thought that only fourteen boxes were required to perform the service. F. P. Furlong, General Post Master of Hartford, who originated the idea, said recently to the STREET RAILWAY JOURNAL that during the first fifteen days of April there were received through this source 9310 letters; during the last fifteen days, 12,899; making a total for the month of 22,209 letters, which included quite a few special delivery letters.

For the postal department the system presents very many advantageous features. Much earlier connections are made with outgoing mails, by reason of the frequency of the service, and it relieves, in a measure, the congestion in the mailing division, by reason of bringing smaller quantities of mail into the office at frequent intervals.

Three Phase Transmission for Railway Service Near Philadelphia

The increase in the number and extent of suburban electric railways near Philadelphia has kept pace with that surrounding other large cities in this country, and Philadelphia is now connected electrically with Wilmington on the south and Westchester on the west, while the extension of roads to the north is being carried on rapidly. These roads make connections in the outskirts of the city with the system of the Union Traction Company of Philadelphia, but the suburban cars do not run into the center of the city, as in some instances, over the tracks of the city company.

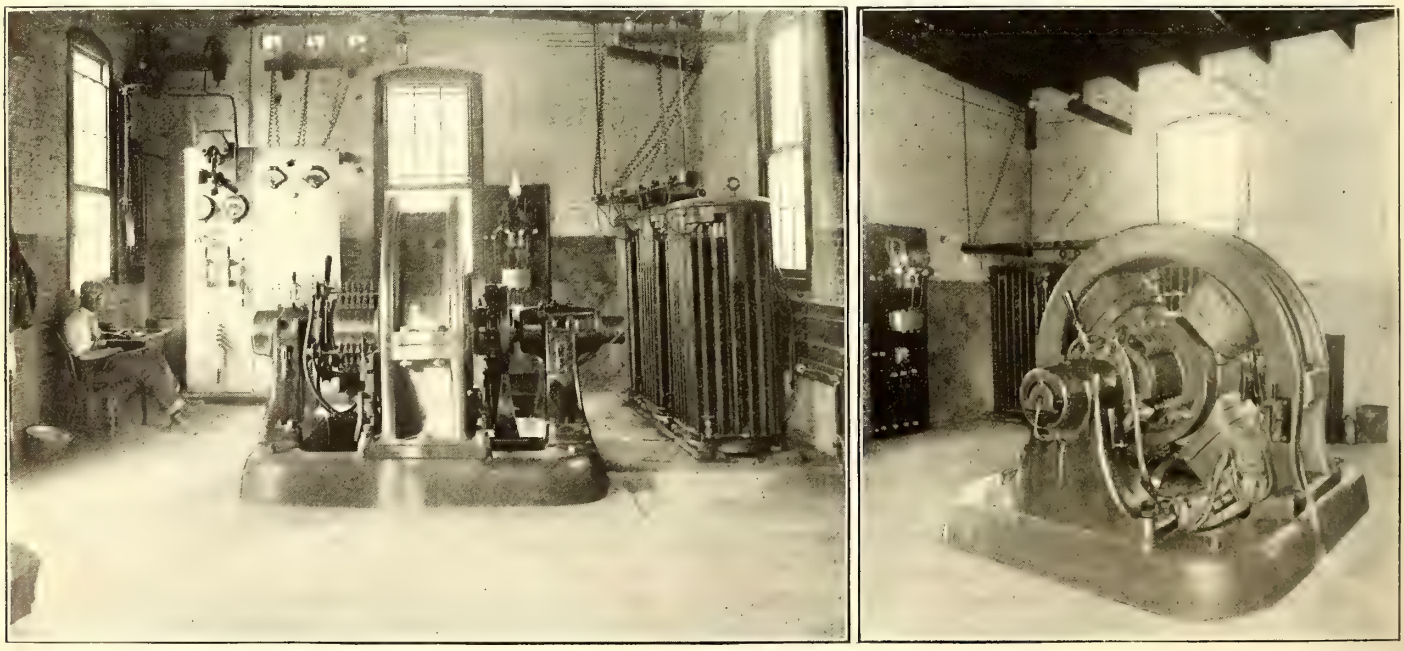
INTERIOR OF MAIN POWER STATION—WESTCHESTER TRACTION COMPANY

Among the lines in operation that of the Philadelphia & Westchester Traction Company is, from an electrical standpoint, probably the most interesting, on account of the use of the three-phase current for power distribution. The line is 20 miles in length, and extends from the corner of Sixty-third and Market Streets, Philadelphia, in almost a direct line along the turnpike, which is controlled by the company, to the Borough of Westchester, which has a population of 15,000. The region traversed is a rich and rolling farming territory, and crosses a series of six ridges and valleys, with grades of from 4 to 6 per cent on each side, some of the grades being over 3500 ft. long. Eight miles of this line, or that from the eastern terminus to Newton Square, were built in 1894, but the old track has been completely reconstructed.

The track is rock ballasted for the entire length, and east of Newton Square is a 58-lb. T rail, furnished by William Wharton, Jr., & Co., with tongue switches, mates and frogs of manganese steel. The ties are 5 ins. x 7 ins. x 7 ft., laid 2-ft. centers. No. 0 trolley wire, with the General Electric overhead material is used. West of Newtown

Square 58-lb. Johnson T rails in 60-ft. lengths are used, laid on oak and chestnut ties of the size already mentioned. The trolley wire on this section is a No. 0000, and double for the entire distance, as no feeders are employed. The overhead material is of the General Electric and McCallum type. Within the Borough of Westchester a 9-in. Johnson girder rail in 6-ft. lengths is used, on 6-in. x 8-in. x 8-ft. oak ties. Mayer & Englund 0000 protected bonds are used throughout. The Ramsey block-signal system is used.

The main power station is at Llanarch, 2¼ miles from the eastern terminal. It is of red brick on rubble stone foundations, and measures 100 ft. x 52 ft. 5 ins. The roof trusses are of steel, supported by steel columns, which also carry the crane girders. The boiler room is 44 ft. x 51 ft., and 20 ft. high, and contains three Pierpont water-tube boilers of 200 h.p. each. These boilers are fed by two No. 10 Sellers injectors, and burn bituminous coal.

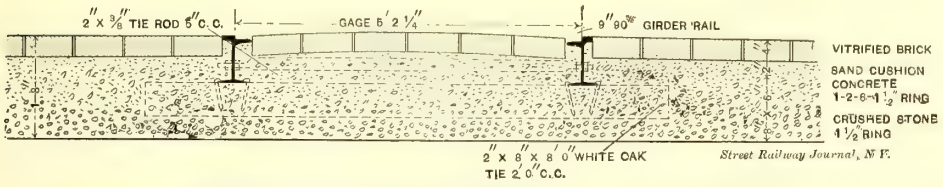


The engine room is 52 ft. 5 ins. x 51 ft., and contains two Harrisburg Ideal compound condensing engines, 17 ins. and 28 ins. x 42-in. stroke, each directly connected to a G. E. 400-kw. generator, with a speed of 100 r.p.m. In the basement each engine is connected with a single cylinder air pump and jet condenser, 12 ins. and 16 ins. x 18 ins., manufactured by the Snow Steam Pump Company, which also supplied the steam pump, which is 10 ins. x 5 ins. x 10 ins. In the engine room is also a 15-ton Sellers crane, operated from the main floor. The switchboard is of the standard type of the General Electric Company, with two generator and four feeder panels.

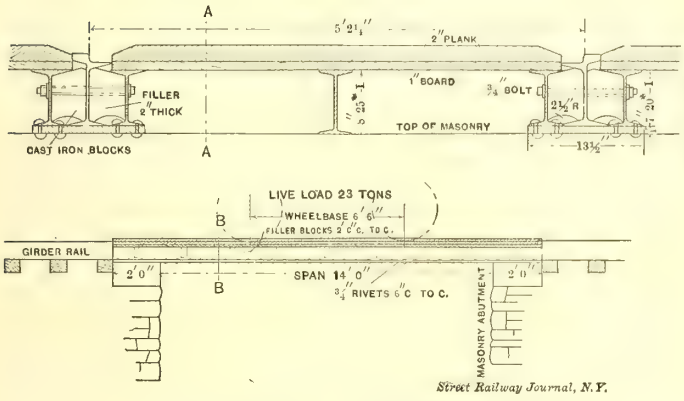
In addition to this machinery, which supplies current to the line from the eastern terminus to Newtown Square, there is also a 250-kw. General Electric rotary converter, taking current from the main bus bar. This converter is of the T C-4-250-750 type, supplying 380 volts on the alternating side and 550 volts on the direct current side, and is run inverted; that is, the direct current side is used as a motor, while current is taken from the alternating side at 25 cycles per second. In the station are also three 90-kw. step-up transformers of 380 volts primary and 6600 volts secondary current connected with the alternating current side of the inverted rotary.

The substation is located at Ridley Creek, is of brick, and measures 19 ft. 6 ins. x 32 ft. It is 10¾ miles from the power station, with which it is connected by three No. 4 wires carried on porcelain insulators. These were supplied by Mayer & Englund, manufactured by Fred M. Locke, and are carried on white pine cross-arms, on pins spaced 12 ins. apart. After passing the lightning arresters, which are of the G. E. A type, the current passes through aluminum fuses, thence to the oil switches on the switchboard, and thence to three oil-insulated 90-kw. transformers, by which it is reduced to 380 volts. At this

EXTERIOR OF ROTARY CONVERTER SUBSTATION

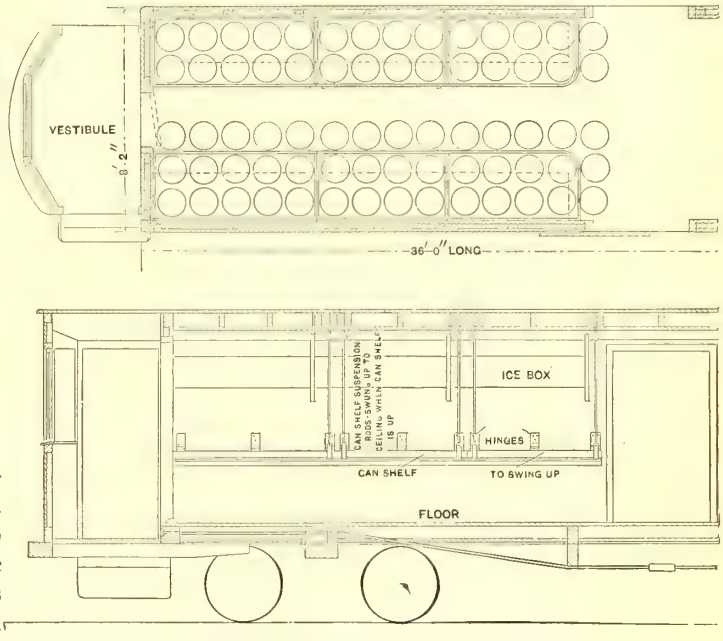


INTERIOR OF ROTARY CONVERTER SUBSTATION AT RIDLEY CREEK



voltage it is taken to the alternating side of the rotary, while from the direct current side a current of 550 volts is supplied to the trolley wire.

Each rotary converter is supplied with a centrifugal governor operated from the extended shaft of the machines. This governor is set so as to throw the circuit breaker on the switchboard, in case the limiting speed, which is about 30 per cent above normal, is reached. The governor consists of two weights, which are thrown out as the speed increases, and when in operation make contact on two rings, which are connected to an auxiliary trip coil on the circuit breaker. On the other side of the machine is placed an end-play device which is in connection with a make and break circuit, which energizes coils and causes a magnetic pull on the armature, thus giving it a to and fro motion in the bearings. The motor for accomplishing this is of the induction class, 4-1/16-750-80 type.



In starting the alternating current system, the rotary converter in the main station at Llanarch is first

SECTION OF TRACK CONSTRUCTION IN WESTCHESTER

SECTION AND PLAN OF MILK CAR

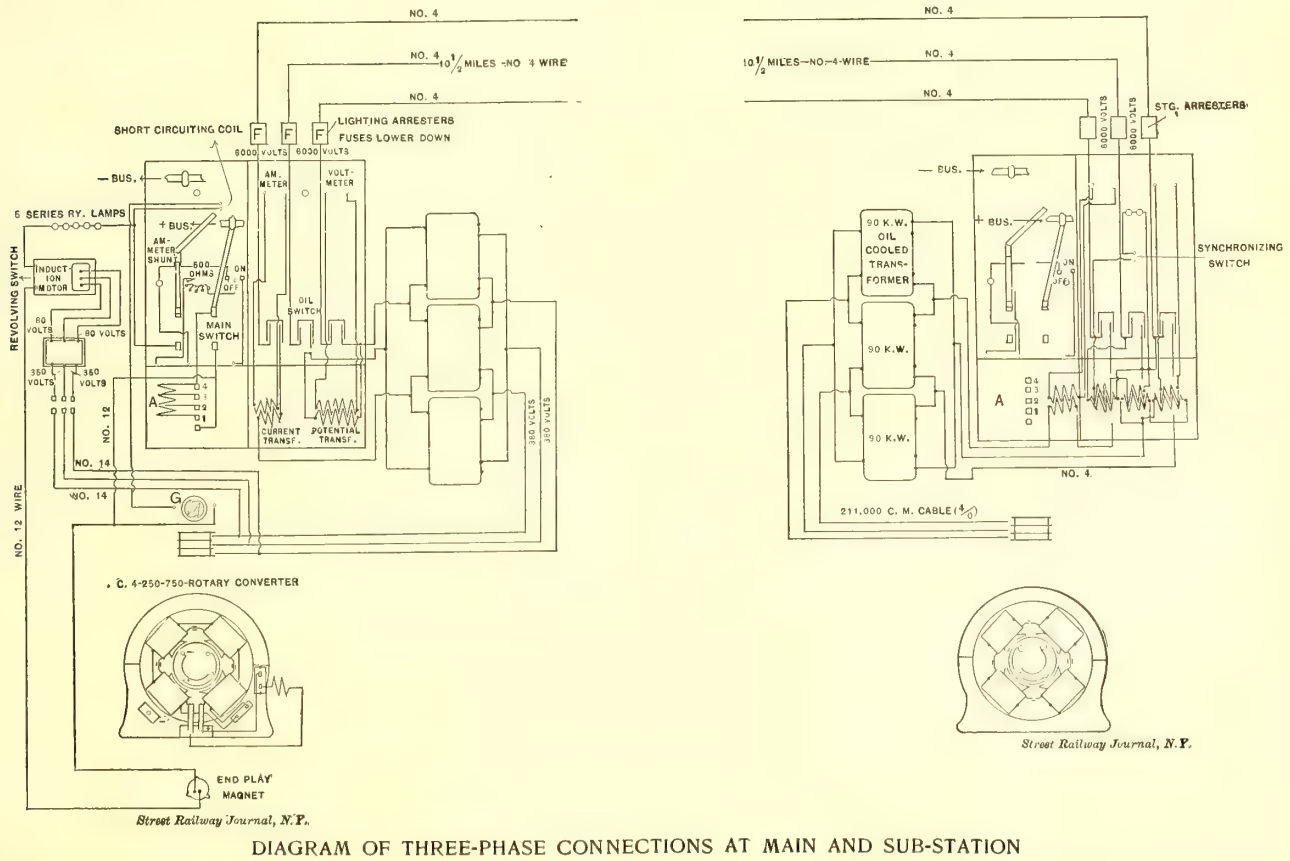

DIAGRAM OF THREE-PHASE CONNECTIONS AT MAIN AND SUB-STATION

run as an ordinary direct current motor, after which that in the substation is started as an alternating synchronous motor from the alternating side. The amount of current necessary to start this machine is about its full load. The voltage on the direct current side of the rotary converter in the substation is practically the same as that in the main station. This voltage rises, along with the compounding of the large 400-kw. generators, in the main station as the load goes on.

For its rolling stock the company has fifteen ten-bench open cars, made by the Lamokin Car Works, mounted on Brill 21 E trucks, and equipped with Westinghouse No. 38 motors; six small box-cars, built by Brill, and six long closed cars, with smoking compartment, built by Jackson & Sharp. These latter, the latest addition to the company's rolling stock, are 29 ft. 6 ins. in frame, 39 ft. over all and 40 ft. over bumpers. They measure 7 ft. 6 ins. wide over sills, and 8 ft. 2 ins. wide over belt rail, allowing 34-in. seats on each side of the aisle, giving a very wide aisle space.

The interior finish of the cars is quartered oak, with white birch veneer ceilings, handsomely decorated. Between the second and third windows is placed a bulkhead, or partition, dividing the car into two compartments. The main compartment, or passenger room, is fitted with Hale & Kilburn's walkover seats, upholstered in rattan. In the smoking-room end of the car side seats of slats of the usual type are placed, giving a seating capacity of four on each side, or eight in all, making the total seating capacity of the car forty passengers. The sashes are double and fitted with polished plate glass; the upper light is permanent. The lower sash is made to drop into the side of the car below the belt rail. The lights in the deck are bevel-edge with chipped center, and the glass in the end doors are also bevel-edge, of plate. The end doors of the cars are double, mounted on contra-twist door hangers. The curtains are fitted with Burrowes Climax fixtures. The cars are fitted with especially long platforms, being 5 ft. 3 ins. over all, detachable canopies and vestibule fronts. The outside is painted Tuscan red, and striped and numbered in gold leaf, and lettered in aluminum leaf, which give very handsome effect. The cars are mounted on Peckham 14 A trucks, and are equipped with Westinghouse No. 49 motors and Christensen air brakes. The cars are equipped with New Haven registers and Johns heaters.

A large proportion of the company's business is the carrying of freight and merchandise, of which the transportation of milk forms a considerable item. To accommodate this service the company has recently put on a new milk car of the form illustrated on the preceding page.

The line is especially built for high speed, and it is the intention of the company to run the 20 miles in one hour and fifteen minutes. There is no direct steam railroad connection between the terminals of the electric road, and it is thought that considerable through business can be secured, as well as a considerable excursion business in the summer. To encourage the regular passenger business, especially on rainy and cold days, the company will build waiting stations at regular points along the line, and they will be lighted and heated by electricity.

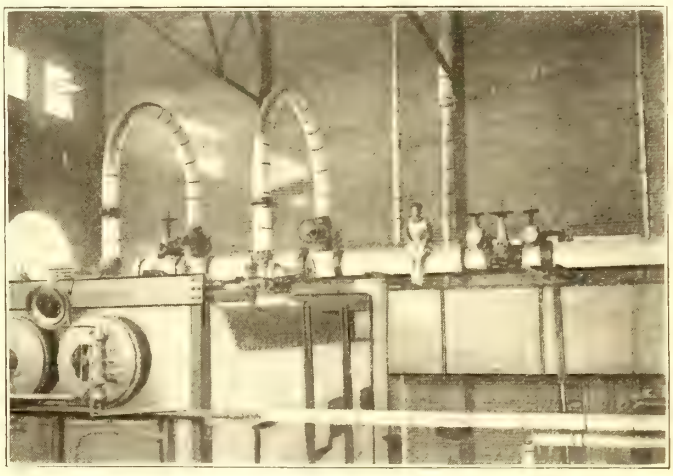
The officers of the Philadelphia & West Chester Traction Company are: President, A. Merritt Taylor; secretary, C. Russell Hinchman; treasurer, Nathan Sellers; electrical engineer, Joseph W. Silliman; superintendent, J. H. Gibson.

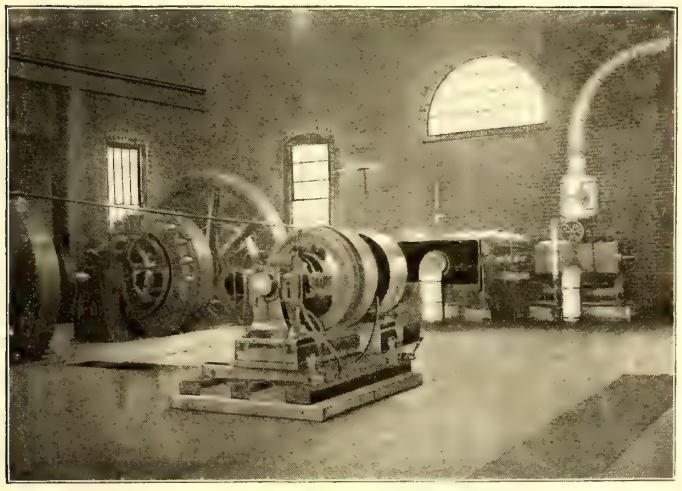
The general contractors were Pepper & Register.

For making inspection and running repairs such as should be made in car-houses, it is a safe rule to have one man to seven cars. From paper at the Boston Convention, 1898.

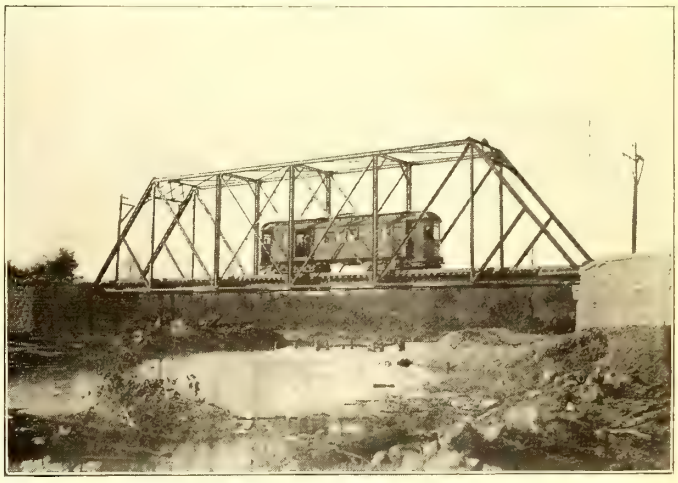


An Interesting Cross Country Electric Road

The Dayton & Western Traction Company, of Dayton, Ohio, in which some of the principal stockholders of the City Railway Company, of Dayton, are interested, is operating an important electric railway extending from Dayton to Eaton, a distance of 25 miles. The line extends through a thickly settled region, chiefly devoted to farming, and containing a number of small villages and towns, notably New Lebanon, Johnsville and West Alexandria. The Dayton terminus is at the Post Office. After leaving the Dayton city line it follows the National Pike all the way to Eaton, and in a distance of 22 miles after leaving the city tracks it has only one slight curve, near the Soldiers' Home. The subgrade of the track, wherever possible, was kept about on a grade with the highway, thus keeping the track high and dry. The maximum grade on the line is 4 per cent, coming out of Dayton. There is also a long grade about 6 miles in length, of 3.85 per cent for 2600 ft. and 3.5 per cent for 1700 ft.



There are nineteen steel bridges on the line, of various lengths, from 10 ft. to 154 ft. They are all built alongside



EXTERIOR OF POWER STATION

VIEW OVER BOILERS

INTERIOR OF STATION

120-FT. SPAN TRUSS BRIDGE AT BANTA'S CREEK

WOODEN TRUSS BRIDGE

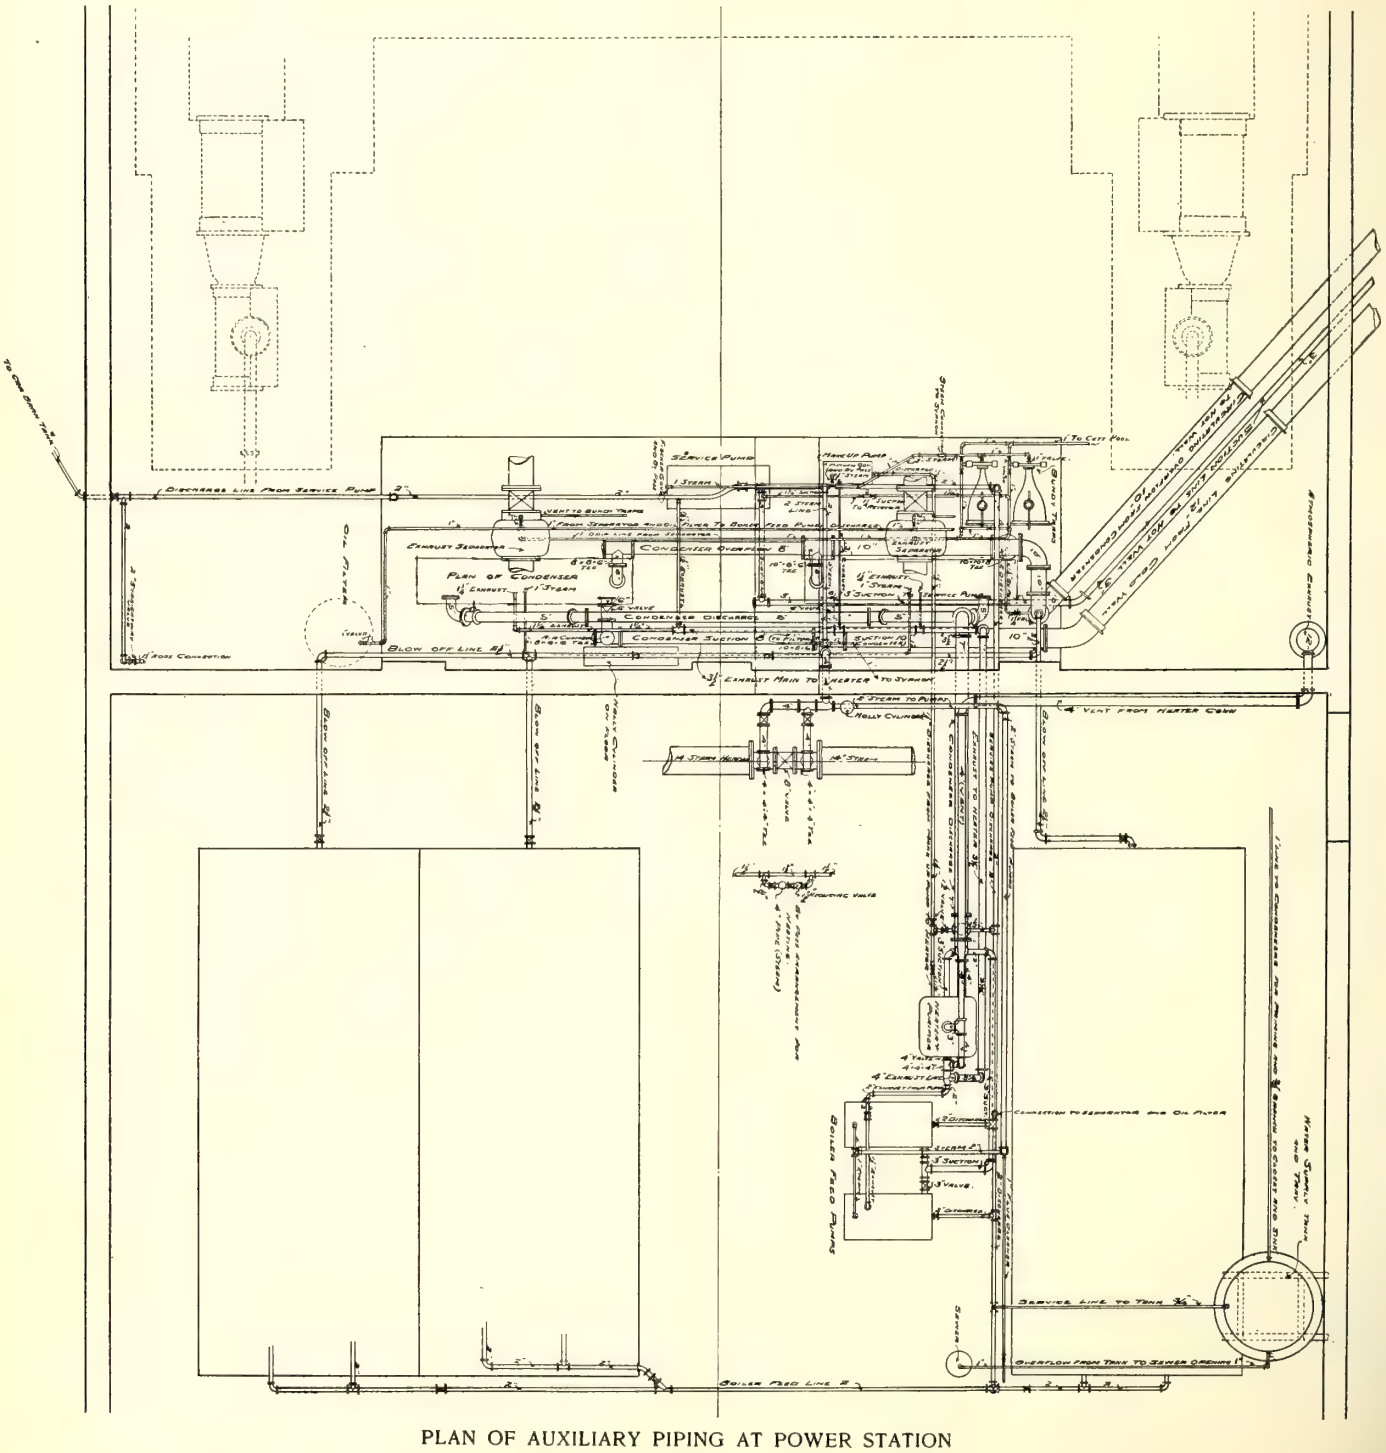


PLATE GIRDER BRIDGE

of the county highway bridges, and have independent abutments. They are all of the deck girder construction, with the exception of one through truss span over Banta's Forks, 118 ft. span. The bridges were furnished and erected by the King Bridge Company, Cleveland.

The ties are principally of white oak, with about 20 per cent chestnut, and were 5 ins. x 7 ins. x 7 ft. 6 ins. The rails are the A. S. C. E. standard, 70-lb. T, 60-ft. lengths, furnished by the Johnson Company. Seven-inch rails are six 300,000 cir. m. feeders of bare wire. There is also a complete telephone system, with boxes at numerous intervals along the road, and telephones in the power house and office and on the cars.

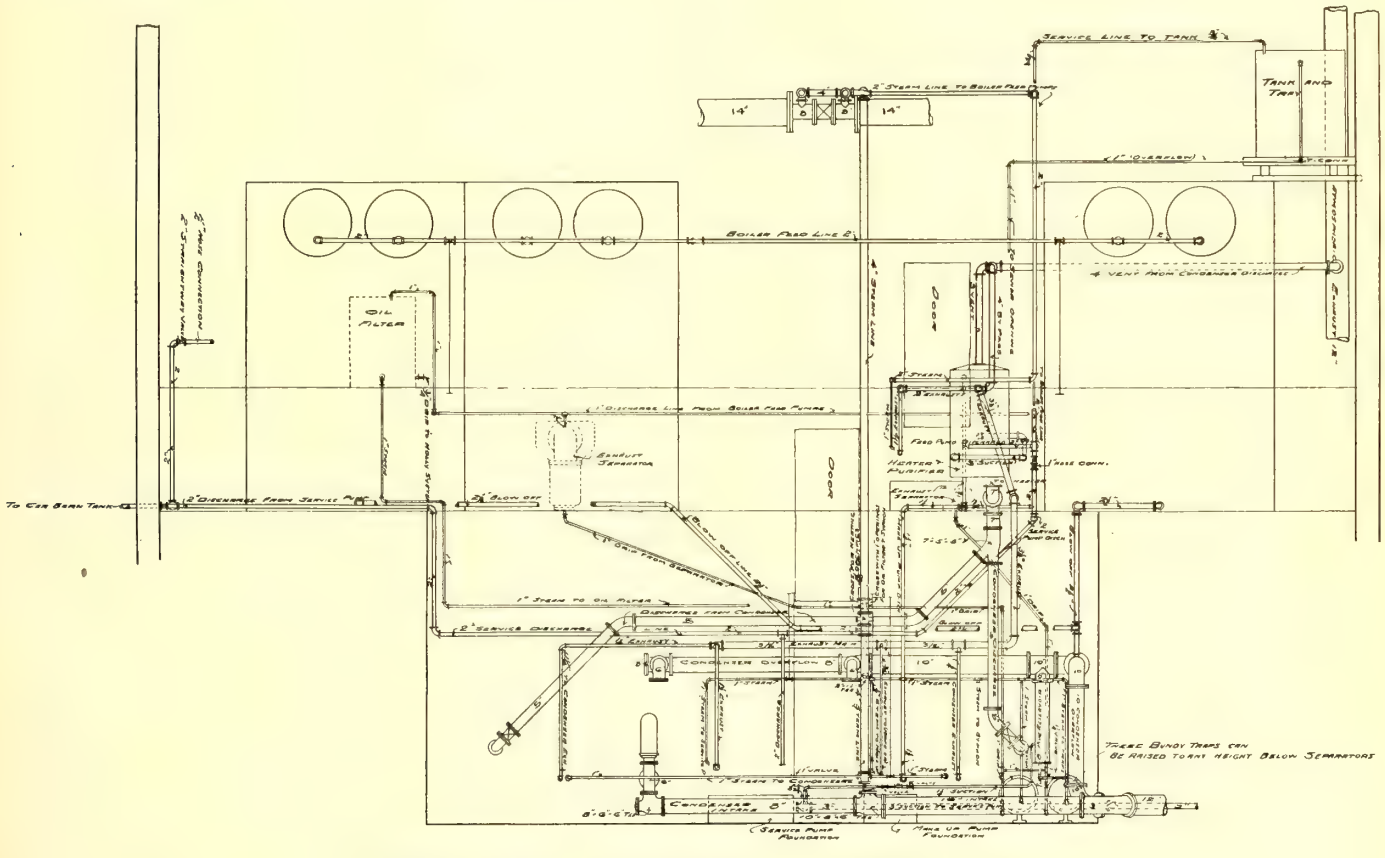
The road has no competition, there being no direct steam road communication between Dayton and any point on the traction line.

The company is at present operating four passenger cars and two combination cars, and transports both freight

PLAN OF AUXILIARY PIPING AT POWER STATION

were used in West Alexandria, and 6-in. girder in Eaton. The track is ballasted throughout with 6 ins. of gravel underneath the ties, sloping 12 ins. outside the ties. The switches are 200 ft. in the clear, and these, with all other special work, were furnished by the Cleveland Frog & Crossing Company. The line crosses the Cincinnati & Northern at West Alexandria, and the Panhandle at Eaton. Derailers are provided at both crossings.

The trolley wire consists of two No. 00 wires, and there and passengers. The fare for the entire trip is 45 cents, or 75 cents for the round trip. The charges for freight are 25 cents minimum for packages, with the regular charge of 10 cents per 100 lbs. for light freight, but special rates are given for bulky loads, such as household goods, and the line is enjoying a very liberal patronage in both the freight and passenger departments. Long eight-wheel cars, with cross seats, are employed. The cars were built by the G. C. Kuhlman Company, of Cleveland, and are



mounted on extra strong Peckham trucks, with two General Electric motors, and with electrical brakes of the General Electric type.

The station was located at West Alexandria, 17 miles from the eastern terminus. This site was selected because it was the only point between the termini where the line crossed a steam railroad, and where coal could be obtained without hauling it over the electric road. It was also the best site for water, as there was no location toward the middle of the road where water was obtainable. It was also thought probable that at some time there might be an extension or addition to the western portion of the line, in which case the power house would be at the center of gravity of the system.

The station building is of brick and is located on the top of a bluff about 1200 ft. from Twin Creek, and about 32 ft. above the level of the creek. The bottom land lying between the creek and the foot of the bluff rises gradually toward the bluff until at the power house it is about 18 ft.

PASSENGER AND COMBINATION CAR

SIDE ELEVATION OF AUXILIARY PIPING AT POWER STATION

VIEW AT TOP OF 3.8 PER CENT GRADE 2600 FT. LONG

below the top of the bluff. Underlying the soil on the bottomland is a bed of gravel, and sufficient water to operate the condensing plant is obtained without the expense of a large pipe line to the creek by driving two wells, about 16 ft. in diameter and 18 ft. deep.

The power equipment consists of two 250-h.p. Buckeye engines, each of which is directly coupled to a Siemens & Halske 250-kw. generator. The engines are tandem compounds, with cylinders 15 ins. and 28 ins. x 30 ins. The units are placed parallel to each other, and the shafts of the generators are extended and coupled with friction clutch with a belt pulley. From this pulley is run a booster, which is placed on a line with the engines, so that it can be driven when one or both of the generators are in service. The booster is rated at 75 kw., and raises the voltage from 600 to 800 volts. It is connected to the line 8 miles from the station. The engine room is provided with an overhead traveling crane, which was manufactured

by the Cleveland Punch & Shear Company, of Cleveland, Ohio.

The steam is generated in two Babcock & Wilcox boilers of 250 h.p. each, and the auxiliary equipment consists of Wheeler condensers and air pump. The coal is delivered directly into the boiler room from freight cars by sidings that connect with the neighboring railroad lines. The operating office of the company is located in one corner of the car house, which adjoins the power station.

The entire engineering for the system was done by E. P. Roberts & Co. and the Osborn Company. In addition to the inspection on the ground, the structural steel was inspected at the mills for the tracks, bridges and structural work in the power house and for the boilers. The contractors for the line were the Chase Construction Company, for the overhead material the Ohio Brass Company, and the line arresters the Garton Company. The engravings for the article are from photographs taken by J. B. Crankshaw, electrical engineer of the road.

Labor Saving Devices in Cincinnati Repair Shops

About a year ago the extensive new repair shops of the Cincinnati Street Railway Company were described in the Street Railway Journal. They have been found amply adequate for the purposes for which they were designed, as well as most conveniently arranged. During a recent visit to these shops of a representative of this paper a number of labor saving devices and other interesting features were noticed.

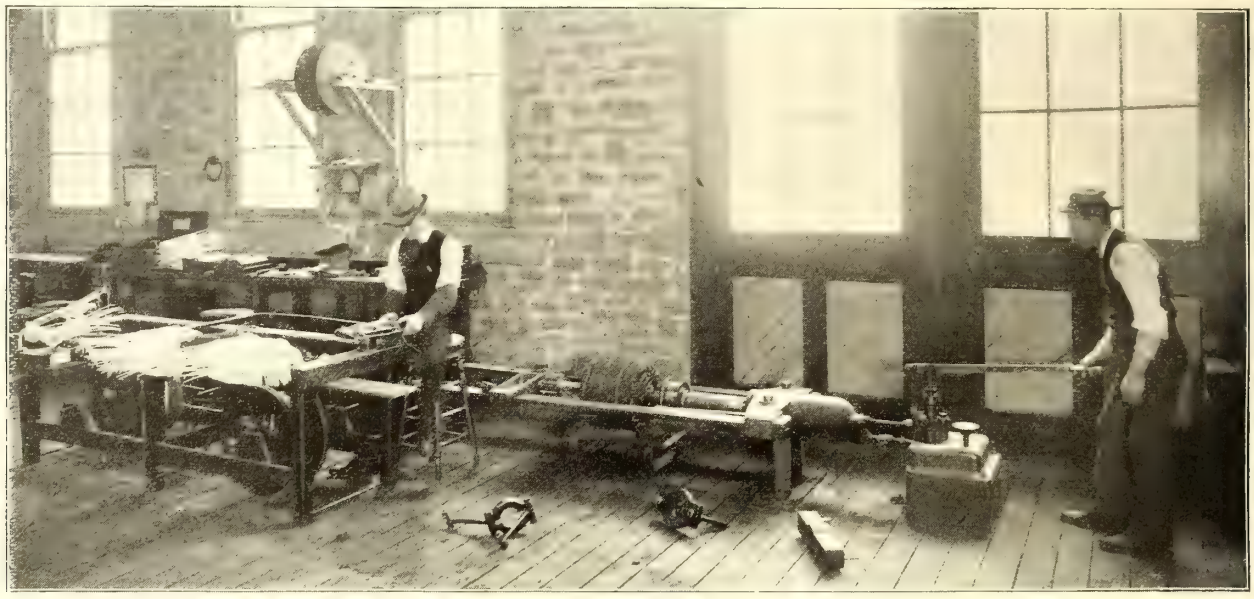

FIG. 1.—MAKING COILS AND PRESSING ON COMMUTATORS, CINCINNATI

FIG. 2.—COIL TAPING MACHINE

In the motor repair department five hands only are employed. These are mostly boys or young men, who work under the direction of an expert repair man, and it will

be noted that this is an exceedingly small force for a railway of the size of the Cincinnati Street Railway Company, especially since it is the practice of the company to wind and tape all its own coils and fields and make all its own commutators. The latter are cast in the brass foundry of the company, of pure copper from the scrap trolley wire that is melted up.

Fig. 1 illustrates some of the forms on which the armature coils are made. In this same engraving is shown a home-made hydraulic press, which is employed for pressing on or taking off the commutators from the armature shaft. This press is operated by a hand lever, as shown in the illustration.

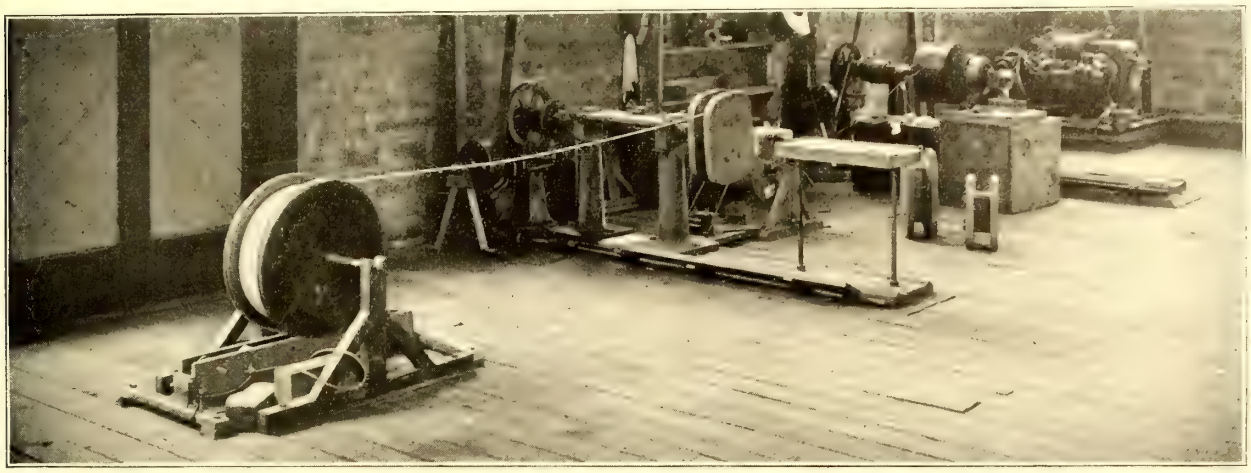

FIG. 3.—LATHES FOR WINDING FIELD COILS AND PLACING BINDING WIRE ON ARMATURES

Fig. 2 shows the coil taping machine, by means of which armature coils are taped very rapidly. This consists of two rings, one operated outside the other by means of a belt which is actuated by foot power, and which causes the ring carrying the spool of tape to revolve. Both the inner, or stationary, ring and the revolving ring are provided with slots which, when brought into conjunction, admit of placing one side of the coil within the ring. As the ring revolves the tape is paid out from the reel which carries it, and which has a governing spring that adjusts the tension. By this device coils can be taped very much faster than by hand. The shops are provided with two of these machines, and a large number of coils are taped up in advance, ready for service, and are stored in the stock room.

Fig. 3 illustrates the method of winding the field coils, which is done on a wooden form. In the same figure is shown a similar device for placing the binding wire on the armatures. These are each operated by power from a belt connecting with an overhead shaft, and the mandril is revolved through the medium of a friction clutch and a worm gear. The clutch is thrown in or out of operation by means of a lever operated by a long pedal, as shown. By this means the mechanism may be started or stopped at the will of the operator. These devices, as well as other shop tools, are operated by power from an electric motor, also shown in Fig. 3.

Four types of motors are employed on the cars of this system, according to the character of the grades and of the cars. They are the G. E. 800 type, the G. E. 1000, the G. E. 1200 and G. E. No. 58, and for testing the armatures of the four different types the device shown in Fig. 4 is used. It consists of a jack shaft driven by belt from a D 62 type of generator that has been transformed into a motor. It will be noted that the cases and fields of four different types of motors are geared to the jack shaft, and are kept in position, the armatures being placed in or removed by means of an overhead hand-hoist. In connection with this testing apparatus is a nest of incandescent lamps, which are cut in and out according to the tension of the current required in the testing.

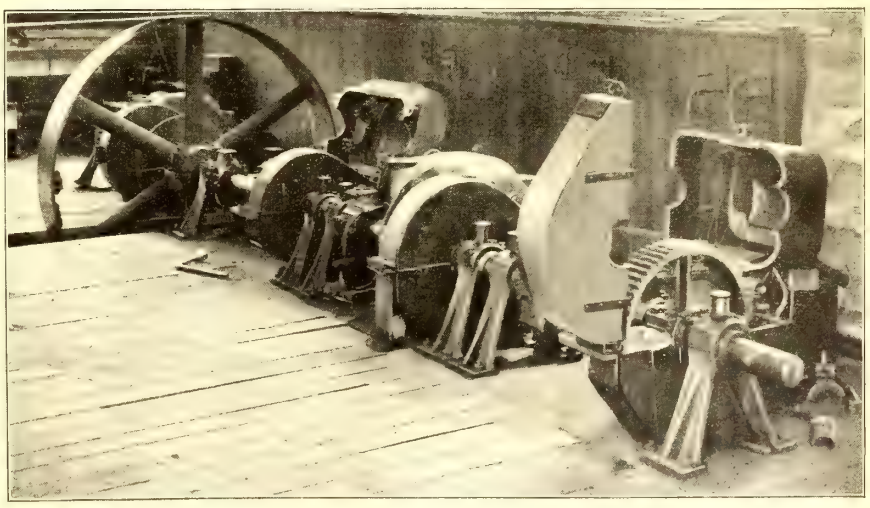

FIG. 4.—APPARATUS FOR TESTING ARMATURES

For treating field coils and armatures Monarch asphalt paint is employed. This paint, when properly baked, proves to be as durable and as satisfactory as to insulating properties as any of the materials that the company has tried.

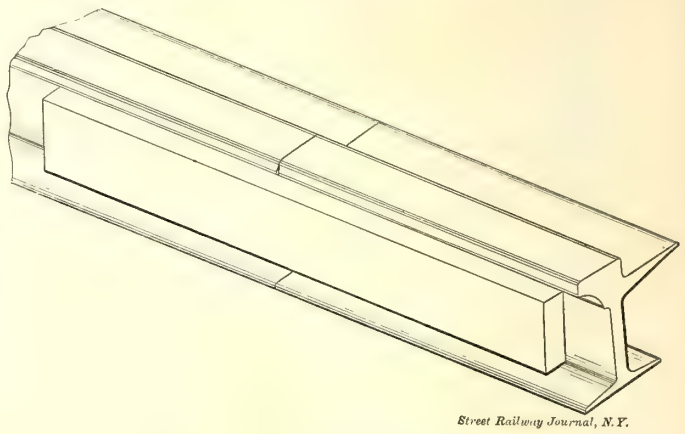
It is the practice to provide two sets of carbon motor brushes for each car motor, and the same for the generators in the different stations. The brushes for the motors are put in service every other day in summer and every three days in winter, and as soon as removed are placed in a pan of sperm oil, in which they are kept until again put in use. The brushes are all numbered and lettered, and are used on the same commutators. By this practice a long life is gotten from the brushes, two sets lasting a year. The practice also adds 100 per cent to the life of the commutator, some of which run for three years. They never require to be sandpapered or touched, but always run smoothly, with a gloss on the surface.

Power for operating the different departments of the

repair shop is derived from motors which are made over from the old D 62 type of generators formerly employed. Quite a number of these are employed, and have proved very satisfactory. There are besides twenty small-power motors employed about the shops and the different car houses of the system.

The company manufactures its own trolley wheels, the blanks being cast in their own brass foundry. They are turned on a specially designed turret lathe, the cutting tool of which works automatically and turns the sides and grooves at one operation. The lathe is operated by an unskilled workman, who receives only $1 a day, but is able to turn up and finish 125 wheels a day. The wheels are cast from a mixture consisting of eight parts of copper to one of tin.

The company employs bronze bearings for armature journals in preference to babbitt, as it was found frequently that the babbitt would squeeze out from the shell and allow the armature to come down in contact with the fields, and in case of excessive heat would melt.

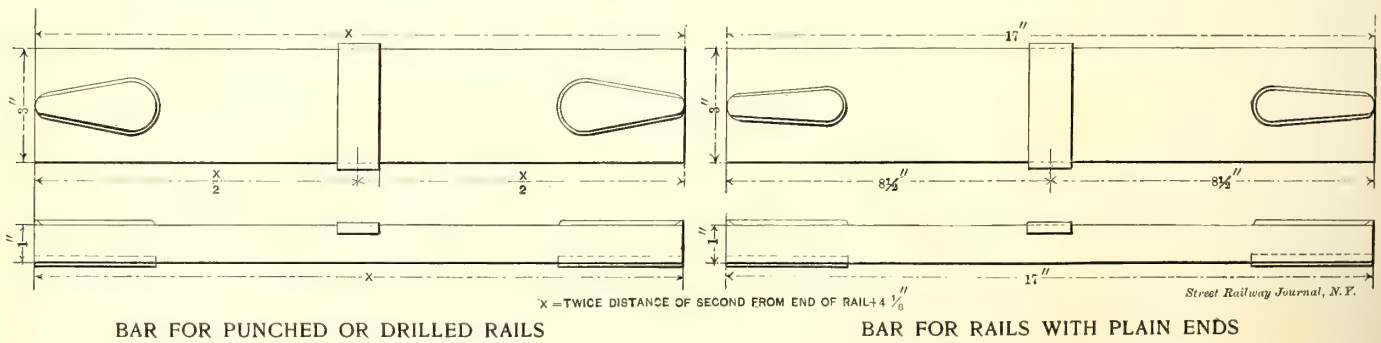


The Present Status of Electric Welding of Rails

BY H. F. A. KLEINSCHMIDT

It will be remembered that in the early welding of rails, as carried on by the Johnson Company, peculiar indications of a change in the nature of the steel were observed. These were attributed for a long time to the electric current. Until the nature of the apparent change could be understood, the company withdrew from the field and entered upon an exhaustive series of experiments. Various methods of heat treatment after the weld was made were tried and discarded. Finally the writer, in endeavoring to prevent the spread of heat after the weld is made, discovered a very simple process which entirely overcomes any change in structure of the steel, and produces a weld of the greatest toughness and strength. This process consists in making a weld from a boss on a bar, instead of from a flat bar. As the boss is the only portion of the bar which comes in contact with the rail, all the heat is concentrated at that point. As soon as a welding heat is reached the current is cut off, and, simultaneously, a heavy pressure is exerted directly over the weld and artificial means provided for hastening its cooling while under pressure. The comparatively cold portions of the bar surrounding the boss prevent the more plastic metal from spreading, and the heavy pressure so confines it that in cooling there is no chance of coarse crystallization. In other words, the effect is exactly the same as hammering or working the steel.

The results obtained experimentally by the Lorain Steel Company have been amply borne out by practice. Even with a strain of 350,000 lbs., we have never succeeded in shearing off a weld made in this way. On making a joint we use a bar 1 in. x 3 ins., having three bosses, as shown in the accompanying diagrams, and weld one bar to each side of the rail web. Bosses of an ovoid shape are used when old rails having punched holes are to be welded. The boss then covers the hole, welds it up completely, and thus removes the danger of old fractures at this point. Holes beyond the bars are reamed. The center weld is made first, then the end welds. The bars, when cooling, exert a powerful force to bring the rail ends together, making a perfectly tight joint.



In 1897 a little over a mile of track was welded in Johnstown. After a severe cold spell during the first winter one break occurred through an old bolt hole beyond the

ISOMETRIC DIAGRAM OF JOINT

welded bars. No further breaks have occurred on this track. Last summer 10 miles of track were welded for the Nassau Electric Railway Company, at Brooklyn. Some of the joints had eight-hole splice bars, and others twelve-hole. In all cases the second hole on the top row was welded over by the end bosses, the bars being placed close under the head of the 9-in. rails. In the twelve-hole punching the holes beyond and directly under the end of the bars were reamed out, our experiments having shown that a punched rail, on account of minute fractures, is very much weaker than a drilled rail. Although the Brooklyn track was welded during the hottest weather, the number of breaks have only been one out of 180 joints, or a trifle over 0.5 per cent. In no case did a rail with the eight-hole punching break. The fractures all occurred through the holes beyond the bars, thus showing that the reaming had not removed all the fractures in every case. With new rails, having no holes, or rails in which the holes are drilled instead of punched, it is confidently believed a break will be an extremely rare occurrence. The fact that no fractures occurred until after severe cold weather set in proves conclusively that they were due entirely to the tensile strain to which the rails were subjected by contraction due to low temperature, and that the old trouble has been entirely overcome.

The experimental stage of the electrically welded rail joint is passed. In electric welded joints we are as sure

BAR FOR PUNCHED OR DRILLED RAILS

BAR FOR RAILS WITH PLAIN ENDS

of our product to-day as in any field of production. With a given size of bar we produce a joint of certain strength and a uniformity of product as perfect as can be obtained.

The ultimate success of the process is due to the indomitable perseverence of Mr. A. J. Moxham, and to his faith that this method offered advantages superior to any form of joint, and that the field to be occupied has hitherto been unfilled.

For electric roads using their rails as a ground return it has manifest advantages. The cost, especially for the 9-in. girder rails which are now coming into almost universal use, is less than for any other form of so-called welded joint. As a bond it offers the only perfect method of reducing electrolysis to a minimum. The intimate union of steel to steel, and the increased carrying capacity due to the bars at the joints, make the joint the place of least resistance. An electrically welded track is of lower resistance than the rail itself.

There is no obstruction to paving, as the flat bar offers as good a surface for paving against as the rail web itself. Ties are not disturbed, as it is not necessary to go below the rail flange in making the joint. A continuous rail joint should last as long as the rail itself, and its wearing qualities should be the same. By our process the head of the rail is heated but slightly, thus avoiding the danger of annealing the rail head and softening it, which is apt to be the case where the whole rail is raised to a red heat when forming the joint.

In the apparatus used at present in this work we have made very few changes. A 75-kw. booster has been added, which permits good welding, even with a voltage as low as 300, and a sand blast apparatus has replaced the old method of cleaning the rails.

The Lorain Steel Company has started upon the electric welding of 50 miles of track in Buffalo, upon the system outlined above. Of this length about 25 miles will be of 60-ft. 9-in. rails, with ends left blank for the style of joint adopted.

Speed Tests on the Cleveland-Lorain Railway

In the last issue of the STREET RAILWAY JOURNAL some results secured in the power station of the Cleveland-Lorain Railway Company were published, under the heading "Analysis of the Operation of an Interurban Railway." Through the courtesy of E. P. Roberts & Co., engineers of that line, the STREET RAILWAY JOURNAL is able to give in this issue some additional statistics upon the speeds secured during trial runs and in regular service. The figures are particularly interesting, from the fact that the line is a high-speed electric road, with practically no grades and few curves. The cars with which the tests were made, the results of which are given, were equipped with four G. E. 57 motors, with gear ratio 1 to 5.7. Each car was mounted on two Brill No. 27 trucks, equipped with 33-in. wheels.

Table I. shows the result of four acceleration tests made in the same direction, with the same car, from the same point, and with the same motorman. The car weighed 23 tons, and the speed per hour given is the average speed between the 10-sec. readings.

Table II. shows four tests with three cars differently

TABLE I.—SPEED TEST WITH SPECIAL CAR.

No. of Car.	Weight of Train in Net Tons.	Grade, Per Cent.	10 Seconds.		20 Seconds.		30 Seconds.		40 Seconds		50 Seconds.		60 Seconds.	
			Speed, Miles per Hour.	Distance Run, Feet.	Speed, Miles per Hour.	Distance Run, Feet.	Speed, Miles per Hour.	Distance Run, Feet.	Speed, Miles per Hour.	Distance Run, Feet.	Speed, Miles per Hour,	Distance Run, Feet.	Speed, Miles per Hour.	Distance Run, Feet.
1.....	23	1 2	9.1	133	20.0	426	20.8	877	37.7	1,430	43.2	2,064	44.0	2,724

Wind was from east to west and 10 to 15 miles per hour variable. Tests 3 and 4 were made over same section of track with same motorman, but different cars and in opposite direction.

loaded, but with the same equipment as in Table I. As with Table I., there was practically no wind at the time of the test.

Table III. shows five tests in different directions, with wind blowing from east to west at from 10 to 15 miles per hour. The track is almost exactly east and west.

Table IV. gives the voltmeter and ammeter readings, with feet, for every ten seconds, corresponding to the last run in Table I., *i. e.*, 1-5 per cent down grade, 23-ton car, with four G. E. 57 motors, etc.

Table IV.—Acceleration Data.

Seconds.	Amps.	Volts.	Feet.	Total Distance.
10	485	500	149	149
20	350	520	344	493
30	275	550	483	976
40	225	570	559	1,535
50	195	575	630	2,165
60	180	580	637	2,802

Table V. gives a selection of readings taken under most favorable conditions at two points along the line. As will be seen, the averages are respectively 31.75 lbs. and 32.53 lbs. friction.

Table V.—Traction Data.

Selections of readings obtained under most favorable conditions. Track practically level and straight.

Place No. 1.

Car.	Bound.	Passengers.	Amps.	Volts.	Speeds.	Wind.
15	West.	0	150	595	45	6 m. per h. East.
15	East.	13	145	575	47	6 " "
15	West.	20	150	570	46	6 " "
11	East.	8	155	580	45	5 " "
13	East.	8	140	535	49	30 to 35 East.
13	West.	14	160	570	40	" "

Average gives 31.75 lbs. friction.

Place No. 2.

15	West.	0	155	615	48	6 m. per h. East.
15	East.	13	145	610	50	6 " "
15	West.	17	155	610	48	6 " "
11	East.	8	155	615	48	5 " "
13	East.	8	135	620	51	30 to 35 East.
13	West.	14	180	600	39	" "

Average gives 32.53 lbs. per ton friction.

The wind is usually from West to East, and on the day readings for car 13, run obtained was quite high and variable as to velocity.

Average of both places gives 32.14 lbs. per ton friction.

Table VI.—Traction Data.

Car No. 15.

	Bound.	Passengers.	Amperes.	Volts.	Speed.
Practically Same Point.	East.	13	145	610	50
	West.	17	155	610	48
	West.	0	155	615	42
Practically Same Point.	East.	13	150	600	47
	West.	20	150	580	48
	West.	0	155	600	45
Practically Same Point.	East.	13	145	575	47
	West.	20	150	570	46
	West.	0	150	590	45

	West.	22	150	600	47
Practically Same Point.	East.	17	140	535	44
	West.	24	140	420	37
Practically Same Point.	East.	17	140	505	45
	West.	24	160	550	42
Practically Same Point.	East.	17	145	505	..
	West.	24	165	510	..

Wind about 6 miles per hour west to east. Average gives 30.8 lbs. per ton friction.

Table VII.—Traction Data.

Car No. 11.

	Bound.	Passengers.	Amperes.	Volts.	Speed.
	East.	8	155	580	45
	East.	8	150	595	48
	East.	8	165	610	47
	East.	8	155	615	48
Same Point.	East.	9	175	600	40
	West.	14	155	605	45
Same Point.	East.	9	152	605	45
	West.	14	150	610	50
	East.	9	165	615	48
Same Point.	East.	9	175	595	40
	West.	15	175	590	43
	East.	10	162	535	37
	East.	10	155	525	48

Average gives 34.6 lbs. per ton friction.

Wind about 5 miles per hour. This car seemed to me heavier than others, this was noticeable from rapidity of retardation when power was thrown off.

The results in Table VI. were obtained to determine the effect of wind resistance on speed. All readings are on the same car, and were taken in some cases while the car was running easterly, and in other cases in a westerly direction. The loading, necessarily, was different, however, as the car was in regular service. Tables VII. and VIII. are made up in the same way, except that other cars were under observation, and the velocity of the wind was different. In each case the equipment of the car was the same, viz., four G. E. 57 three-turn motors on Brill No. 27 truck, 33-in. wheels and 1:5.7 reduction.

Table VIII.—Traction Data.

Car No. 13.

Bound.	Passengers.	Amperes.	Volts.	Speed.
East.	10	140	535	..
West.	14	160	570	40
East.	10	150	600	..
West.	14	175	590	43
East.	10	135	620	51
West.	14	180	600	39
East.	10	145	610	40
West.	8	160	600	40
East.	10	145	550	45
West.	8	160	550	40
East.	10	165	535	48
West.	8	155	530	40
East.	10	145	560	45
West.	8	165	500	38
East.	10	140	525	45
West.	8	150	525	38

Average gives 32.6 lbs. per ton friction.

Wind high 30 to 35 miles per hour, West to East, and variable velocity. Very fair tests, as had few stops having mostly through passengers.

Carrying Mail in Germany

The carrying of mail pouches has been a part of the street railway business in Germany for some time. The manner in which this has been done is that a postal clerk, by paying the full or partial fare, traveled as a passenger and guarded the bags, or if but one or two pieces had to be transported at a time, the bags were placed on a certain car at a definite time by a postal clerk, and there were guarded by the motorman until the car reached its destination, where the matter was delivered to another postal clerk by the motorman.

Up to now these have been the only methods employed. Recently, however, special agreements have been made between the imperial postal service and the larger street railway lines, such as that in Berlin, to the effect that the companies will operate, for a certain compensation, specially constructed mail cars over their lines. Already most of the roads which are subject to the Prussian laws governing street railway lines have been obliged to have such a clause inserted in their original franchise; they would gladly have consented, however, without such compulsion, to transport merchandise—although originally the lines were intended for passenger traffic only—as considerable profit can be derived from such service.

With the transportation of mail, however, the exclusive use of the lines for passenger traffic has become changed, and there is a growing demand in a number of cases to introduce a parcel express service. In the granting of new franchises the municipalities have insisted in several cases that the roads for a certain consideration will transport corpses, the city's building material, such as paving stones, etc., as well as convey refuse matter; and at Hamburg they are even compelled of late to transport cattle to the slaughter houses.

LETTERS AND HINTS FROM PRACTICAL MEN

Notes on the Standard Rules and Regulations as Reported by the A. S. R. A. Committee, V

Schenectady Railway Company.

Schenectady, N. Y., May 19, 1899.

Editors Street Railway Journal:

Concluding the comparison and analysis of the "Standard Rules and Regulations" of the A. S. R. A. committee, we wish to know:

12. Are they free from unnecessary repetitions, either within themselves or with one another? Rule No. 8 for Motormen is an exact duplicate of the first part of Rule No. 17 for Motormen and Conductors, and Rule No. 12 for Motormen is an exact duplicate of the last part of this rule. The latter part of Rule No. 18 for Conductors and Motormen is a repetition in idea—though not in phrase—of the latter part of this same Rule No. 17 and its duplicate, No. 12, thus triplicating a rule. The second paragraph of Rule No. 14 for Conductors repeats the same ideas as Rule No. 23 for Conductors and Motormen. These are specific instances of repetitions and duplications where the language and ideas are identical, and there are several other cases where the idea or general meaning is repeated. Now, it is true that the above repeated rules are important "safety rules," and neglect of them has probably caused serious loss to many companies, but they are not so important as *some* of the safety rules, and not a bit more important than some of the others that have not been repeated in either ideas or language. If the idea of the committee has been to make repetition act as emphasis to particularize important rules, their ideas of the relative value of rules are, to say the least, peculiar.

The value of any particular rule or rules is, with the exception of possibly one—that relating to accidents—very hard to fix—in the rule book. It is a difficult task to impress on a new employee by anything in the rule book the true value or importance of even the rules that the employer considers most important; it may be possible to impress him with one or two, which show their value on their face, but anything beyond that tends to bewilder him and give him false ideas. The true—and the relative—importance of a rule, or rules, must be mainly learned in his practice of them, and for this reason it is best in the rule book to emphasize only *one* of them—the one treating of the management and reporting of accidents, and to emphasize this one in some other way than by repetition. Any other rules may have their salient points emphasized by italics, capitals, etc., but in no other case should any one rule be emphasized as a whole. The sense of the value of the rules and of care and responsibility must be impressed on the new employee by the palpable clearness, completeness and logicality of the rules, by the care inculcated in their use, by the precepts and practice of his superior officials, by the example of his fellow employees, by the rewards and punishments meted out by his employer, and *not* by the inane repetitions of certain rules, ideas, or phrases.

13. Are they free from unnecessary, irrelevant, or axiomatic remarks and directions? Unhappily they are not! This point has been gone over in another article, but something still needs to be said on the subject. Rules are virtually specific "instructions," and as such should be as formally concise as is possible, everything necessary to the subject *must* be included, everything unnecessary *must* be excluded, therefore such remarks as "It is your duty to do so-and-so," "you will be held responsible for not doing such-and-such," "never do" such a thing, should not be placed in the rules—they are unnecessary, besides being senseless.

Other unnecessary remarks and directions are those which treat the new employee as an uncivilized savage, a hardened tough, or an idiotic imbecile, by pelting him with orders not to do some one or more of a hundred things that no sane civilized person would think of doing in the street railway service at present, especially if, as should be the case, the example of his superior officials and of his co-employees shows him at once that such things would not be tolerated for an instant. If the street railway industry were an absolutely new one, and the committee were making the rules for the very first street railway in existence, such orders and remarks might be tolerated, but with the developments of the last few years and the higher class of men now employed as conductors and motormen, the "usages" of the street railway have reached a higher plane, and these usages—the "*lex non scripta*" of the profession—can be safely trusted, in a set of general rules, to take the place of such remarks as have been instanced and spoken of.

14. Are they unnecessarily peremptory in tone? Do they use "must" and "shall" and "never do this and that" more than is needful? They certainly do! Now, while this is not a vital point, it is one of the minor ones that is worth considering as going to make perfect discipline, *not* the stiff-starchedness of military discipline, where the supreme authority and the power of life and death are behind the "orders;" *not* the dread of strict authority and the *letter* of the rules; *not* the fear of fines, suspensions and dismissal; but the heart-whole, cheerful, willing and intelligent obedience that makes a unit of the employees in their employer's interests; *that* is the true discipline of a street railway service, and to conserve which it is not necessary to use peremptory terms except as a means of emphasis in special cases, or—as in the case of the "qualification rules," where a standard is set to which all employees of a certain class must conform. To state in a rule that an employee "will" do such and such a thing is to make him feel that he does it voluntarily, or is *led* to do it; to state that he "must" or "shall" do it, is to make him feel that he is being *driven*.

15. Are they addressed to the second person, "you," or do they address the employees impersonally as "he," or "they," the latter preferably, for reasons given in a previous article? They do both; they mix these "persons" up in a way that would make the average employee wonder who he was. This is another point that is not vital; it is one of the "little things," but it only takes a little care in composition, and if strictly carried out adds to the force and appearance of the rules—unluckily it adds also to the elegance of their phraseology!

16. Do they threaten? No; the rules themselves are free from this defect, but—following Rule 23 for Motormen is a section entitled "Penalties," which invites criticism, both from its location—which may have been an inadvertence on the part of the committee—and for its contents. In its first paragraph is given a list of offenses that "are considered good grounds for dismissal from service," and among these are included dishonesty, lying, drunkenness, reckless running and—smoking and reading newspapers! This reminds one of the "good old days" when a person was hung for murder—and also for stealing a pig! Had the committee left out proven insubordination, dishonesty, lying, drunkenness and recklessness, which are *crimes* in any service, and therefore "dismiss" of themselves, and said "while on duty, the following, if repeated

or persisted in, will be good grounds for dismissal," there would have been some reason in the statement, although it is—in the writer's experience—bad policy to explicitly and formally specify dismissal for anything except the five "crimes" mentioned above. To all the other offenses and faults there are often found, on close and impartial examination, so many mitigating circumstances that a rigid application of a dismissal rule for such minor offenses as are given among those specified by the committee would be unjust and unwise.

The old quotation, "a little learning is a dangerous thing," is aptly illustrated in the case of new conductors and motormen. Knowing their own complete ignorance at the start, they are then very teachable, but when first "turned in" and put on "extra," or "regular extra" runs they will, despite previous good training, get the "big head" and run amuck among the rules. This is recognized by all who have the training of men as the first "critical period," and it is at this period that the disciplinary power of the official is shown. If it is of the "Medes and Persian" order, the employer will lose many good men—much potentially good material. If it is of the jelly-fish order, the employer will gain many poor men—much potentially bad material.

If, however, the discipline is of the kind that reckons on the "human element" among the employees, if it does not expect wings to sprout on their shoulders as soon as they enter the service, if the employer has the three "knows"—knows his business, knows his men, knows *himself*—then at this "hour of trial" to both the employer and the employee, cast-iron rules will not prevail as regards minor offenses, and the employer will be the gainer by so many "ripened" employees, men who have learned through hard experience that they "don't know it all"—the most valuable lesson that can be learned, and one that can only be learned by experience—the experience of failures—and for which the committee would recommend unlimited dismissal!

The second paragraph of this section recommends two punishments "for other offenses not meriting dismissal," although after the sweeping list just preceding, it would be a little hard to tell just what these "other offenses" could possibly consist of! Suspension without pay is damned without a hearing, which is unwise. *Indiscriminate* suspension without pay *is* unwise, but the writer has seen cases where the suspension without pay gave lasting good effects when other measures failed, and it did not "encourage dishonesty, hatred and discontent." "Punishment" is, as a rule, to be avoided if possible, but "it takes all kinds of men to make a world" (likewise a street railway), and, as we have been assured for ages "that one man's meat is another man's poison," it is as unwise to avoid all punishments, or to limit their number and kind, as it is to accord dismissal for pretty nearly every possible offense. The "Mikado's" practice "to make the punishment fit the crime," while a novelty in law, was hardly one in discipline, as many a successful superintendent and manager will testify.

To conclude: The members of the committee have asked for criticism—it is due them, for the report, if left unquestioned and uncriticized, might have had influence with those unfamiliar with the subject, and have done considerable harm.

In view of the fact that the Railroad or Street Railway Commissioners of some States are suggesting the promulgation by themselves of a set of rules—or at least of a set of *safety* rules—the use of which is to be enforced on the roads under their jurisdiction, it behooves the street railways of any State having such a Commission to see that such rules are those which *their* experience shows to be good and proper, and that they are put in, at least, *usable* shape. It also behooves the A. S. R. A., in its capacity as a *national* organization, to see that these rules as they are promulgated in one State after another, are as nearly uniform as possible, so that such inconsistencies as are manifested in such State laws as those in regard to—for instance—bankruptcy and divorce, do not occur in rules which may have the force of laws, and which—under the increase of interstate operation and ownership—may affect many corporations and employees. For this reason it is the province of the A. S. R. A. to set a committee of its own the task of preparing a set of *general* rules to be submitted to the various *State* Street Railway Associations for criticism and suggestion, with a view to making them *uniform* and *standard* for the whole United States, or for such of them as now have Railroad or Street Railway Commissioners, or legislative bodies or committees of like character and powers. If such action is not *promptly* taken by the A. S. R. A., and carried out thoroughly and effectively, we may within the next few years see a heterogeneous mass of conflicting and inefficient rules in adjacent States—beside which the present divorce laws and the rules suggested by the committee will seem good, clear, equitable and consistent.

H. S. Cooper.

Power House Operation

Cleveland, Ohio, May 18, 1899.

Editors Street Railway Journal:

An explanation should be made of the power house report at the top of page 267 of the last issue, in which the kw. hours per car mile are given as 3.4 and the lbs. of coal per car mile as 21.8. This to a certain extent is misleading as to the economy of the plant, as this figure includes the electric heating and lighting load, as well as the steam used to heat the large pavilion. No devices are installed for measuring these separate items, so that an estimate must be made of the amount of power consumed by each, in order to reduce the figures to the net kw. hours and net pounds of coal required to produce a car mile.

During the week referred to the pavilion required heat during a large part of each day, making an average of one-half of the total heating surface for 16 hours per day, or 112 hours per week. There are 7000 sq. ft. of radiation, and at 130 sq. ft. per h.p., this requires 54 boiler h.p. One-half of this, or 27 h.p., at 4.5 lbs. of coal per boiler h.p., gives a total of 13,552 lbs. of coal used per week for heating. Call this 13,500 lbs. 121,465 lbs. — 13,500 lbs. = 107,965 lbs. coal used for the week in running the road, including heaters, light and machine shop motor. 107,965 ÷ 22,451 = 4.81 lbs. coal per kw. hour.

Taking up now the electric heating, there are two cars on the line for 21 hours each day, and generally one in the station, all using current in the heaters. The machine shop motor and lights also take current, making the average steady load, exclusive of that taken by the car motors, about 40 amps. for the 21 hours. This is exceeded when the machine shop motor is running with the car lighting, but drops below when the lights are turned off, and also when the motor is stopped. 40 (amps) × 700 (volts) × 21 (hours) = 588 kw. hours per day, or 4116 kw. hours per week. Deducting this from the total for the week given results as follows: 22,451 — 4116 = 18,335 kw. hours per week, or 2,619 per day, and this, with the average of 823 car miles per day, gives 3.18 kw. hours per car mile, instead of 3.9. 3.18 kw. hours per car mile at 4.81 lbs. coal per kw. hour gives 15.3 lbs. coal per car mile, instead of

the 21.5. These results more nearly agree with the results obtained during the week ending May 14, 1899, during which there was little or no heating, and but little lighting; *i. e.*, total kw. hours per week, 20,798; average coal per kw. hour, 5.5; deducting for the machine shop motor, 10 (amps.) × 700 (volts) × 10 (hours) × 6 (days) = 420 kw. hours per week. This gives 20,378 kw. hours per day. There were 8,795 car miles, which makes the averages 2.31 kw. hours per car mile and 12.7 lbs. coal per car mile. No records are kept of the time which the service pump runs, so that no allowances are made for same.

Referring to the decreased coal consumption per h.p. and per kw. hour, this is very well shown by the record for the two consecutive weeks ending April 30 and May 7, 1899. The first week was run under regular one-hour schedule, and beginning with the second week cars were added to make one-half-hour schedule between 7.15 A. M. and 9.45 P. M.

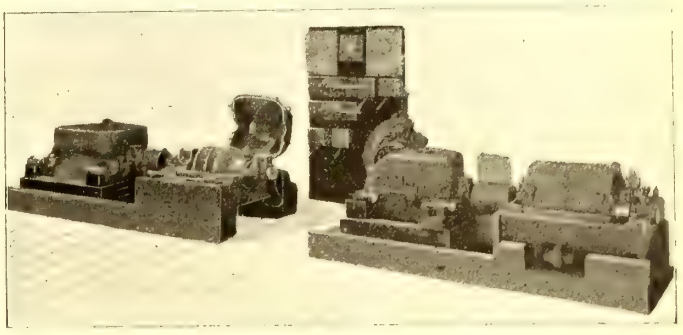
	Week Ending April 30,	May 7, 1899.
Total kw. hours	15,273	19,741
Total coal	101,145 lbs.	107,245 lbs.
Average kw.-hours per day	2,181	2,820
Average kw. per hour	103	134
Average coal per kw.-hour	6.6 lbs.	5.4 lbs.
Average coal per h.p.	4.9 lbs.	4.0 lbs.

Yours truly, E. P. ROBERTS & CO.

An Argument Against Rear Grab Handles

DENVER, May 3, 1899.

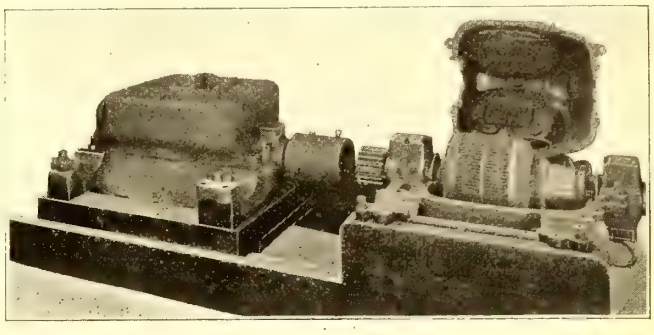
EDITORS STREET RAILWAY JOURNAL:



A large percentage of the accidents which occur on street railways is caused by ladies, and others unacquainted with traveling, stepping from the cars (before they have stopped) and facing in the direction other than that in which the car is going. My impression is that this practice is caused because they are not accustomed to use their left hand. If this opinion is correct, many accidents might be averted if the rear grab handles were dispensed with. I make this suggestion in hope that the cause, whatever it may be, is learned and efficient preventatives applied.

JNO. C. HENRY.

Testing Armatures in Repair Shops



It is most desirable to thoroughly test all apparatus repaired in the shops, rather than run the risk of its breaking down on the road, but the trouble of putting armatures into the motor fields and giving them a practical test under load has sometimes induced superintendents to remain content with the ordinary magneto tests. An ingenious arrangement for testing armatures quickly, however, has recently been devised by Mr. Adams, master mechanic of the North Jersey Street Railway Company of Jersey City and Newark. This device has been in use in that company's repair shops on the Plank Road for some time with excellent results.

Mr. Adams has mounted a G. E. 1000 field rigidly in a wooden frame, and next to it a G. E. 1200 field, arranged so that it can be slid in a direction parallel to its armature shaft. In mounting these motors armature shafts are kept in line. The upper halves of the fields are arranged so that they can be lifted back without unscrewing any bolts, the place of the bolts being taken by taper keys. When a G. E. 800 and 1200 armature have been repaired in the shops they are carried to the motors on a traveling hoist and lowered into their places, the pinions coming opposite each other. The 1200 motor is then slid along its ways until the pinions touch, and the two are connected together by a sleeve, which surrounds the pinions and is fitted with six set screws which fit between the teeth. One motor is then run from the railway current, operating the other as a generator, the current for the second motor being taken

TESTING RACKS FOR ARMATURES

up by a water rheostat. A switchboard, located near the testing device, gives the amount of current used and generated. After having run in this way about seven and one-half minutes, the connections are changed by a double-throw switch, so that the former generator becomes a motor and the former motor a generator, thoroughly testing both machines. Adjoining this is another testing rack of a smaller type, made up of a Westinghouse No. 3 motor and a G. E. 800 motor.

RACK WITH ARMATURES DRAWN APART

In front of the motors is a large frame for holding the armatures to be tested. Every armature which leaves the shops is taken directly to this place to be tested, independent of the extent of the repair, even if it is only the replacing of the canvas on the end of the armature.

The entire system is very simple, and it takes only a few minutes to change the armatures on both machines, and the entire process can be carried on by one man and helper.

Municipal Regulations in Germany

An instance of the minuteness of the German municipal regulations in regard to street railways is shown by a recent ruling of the Police Department, that it is dangerous for a conductor to pass along the steps of open horse cars which have transverse seats. The railway company has therefore been obliged to cut a passage through the seats and end partitions of some cars that it has been operating. As the width of the cars in Germany is restricted to 2 meters (6 ft. 6¾ ins.) outside, this ruling reduces the carrying capacity 25 per cent, so tht a six-bench car will seat but eighteen people. Standing inside is prohibited on all German roads, but a limited number may stand on the platforms; this limit, however, which is plainly posted, is strictly enforced.

NOTICE.

Papers and correspondence on all subjects of practical interest to our readers are cordially invited. Our columns are always open for the discussion of problems of operation, construction, engineering, accounting, finance and invention.

Special effort will be made to answer promptly, and without charge, any reasonable request for information which may be received from our readers and advertisers, answers being given through the columns of the JOURNAL *when of general interest, otherwise by letter.*

Street railway news and all information regarding changes of officers, new equipment, extensions, financial changes, etc., will be greatly appreciated for use in our Directory, our Financial Supplement, or our news columns.

All matters intended for publication in the current issues must be received at our office not later than the twenty-second of each month.

Address all communications to

The Street Railway Publishing Co.,
Beard Building, 120 Liberty Street, New York.

A most valuable aid to the work of a building engineer on electric railways is a portable camera by which he can retain views of the construction of a power station or roadbed while in progress of completion. These views may often prove of value after the construction has been finished to show how certain portions of it were installed, as well as form an interesting souvenir. Important records, also, can often be made with a camera on operating roads by the superintendent or other officials.

Punctuality in running times is one of the best methods of securing and retaining business, particularly where cars are run on long headway and a person desiring transportation has to wait for a considerable time if he misses a car. This is so well recognized as to be almost a truism, but the best of care in timing cars at the termini of lines or at widely distant points on long distance lines does not prevent the motorman from departing from his schedule sometimes, especially if no particular system of checking this feature is adopted. It would not seem a difficult thing to do to establish frequent points along the line of a railway, such as by numbering certain poles, and the employee would then know whether he were behind or ahead of his schedule by comparing the time at which he passed these poles, as indicated by a watch carried on the dash, with the proper moment as given in his time card. Inspectors could be instructed to check up the crew, if necessary, by boarding the cars at different points and comparing the attained time with the schedule.

The ability to study each problem separately and suggest the remedy which is best suited to the conditions, is as important in electric railway work as in any other industry. There are so many factors involved in economical operation that it is not safe to assume that the same solution will do in every case. An instance of this occurred upon a railway recently where it was found that adding 4000 lbs. to the weight of a car cut down the watt output. This anomalous condition was caused by the topography of the road. It was in the form of a single track loop, with a comparatively steep grade near the power station, and a gentle descending grade for the rest of the line. The lightly loaded cars would not descend this grade without using current, but the heavily loaded cars required the use of motors only at starting. The result found was that when the line losses and motor losses for the lightly loaded cars, while on the loop, were compared with those of the heavily loaded cars when mounting the grade near the station, the former were found to be in excess.

Governor Roosevelt, in a recent speech made in Buffalo, said, in referring to the subject of taxing franchises:

"On the one hand we have the perfectly simple savage who believes that you should tax franchises to the extent of confiscating them, and that it is the duty of all railroad corporations to carry everybody free and give him a chromo. On the other, we have the scarcely less primitive mortal who believes that there is something sacred in a franchise, and that there is no reason why it should pay its share of the burdens at all."

In this enumeration, the Governor omitted to mention a third variety of political economists, whose teachings are equally fallacious and far more dangerous to the public than either of the two described. This is the *soi-disant* reformer, who thinks he takes a middle course between the other two views when he advocates franchise taxation and lower fare bills or the absorption of quasi-public corporations by the municipality without any knowledge of or investigation into the real conditions under which these companies operate. It is comparatively easy to protect property against the believer of direct confiscation. It is the person who advocates indirect confiscation under the plea that because in other countries and other conditions street railways do so-and-so, that is the most dangerous to the community.

The electric system has monopolized the attention of street railway engineers for so many years, and its advan-

tages have been so thoroughly demonstrated, that the claims of other powers during the last decade have received scant attention. The latest claimant for a hearing to demonstrate its ability to compete with the electric system, however, is compressed air—latest, not because trials in this power were not made before or concurrently with the electric system, but because the use of compressed air under high pressures as now being tried in this country is entirely new in the history of its application to railway service. Mechanically, the air power motor has been most carefully designed and it is our opinion that if the system should become a successful competitor of the electric for street railway use, it will be upon the general lines described elsewhere in this issue. It is needless to say, however, that some time must yet elapse before absolute figures as to the cost of operation in regular conditions of service on a large enough scale to make this comparable with electric railway service, can be secured. In many respects the system is an attractive one, but it remains to be seen whether there may not be troubles which are not now apparent, but which may militate strongly against its employment.

Elsewhere in this issue a description is published of the use of the three-phase system for current distribution upon a long interurban line. The small percentage drop secured by the use of high tension currents makes the system an attractive one; a number of these lines have been built during the last year or two, and a much larger number is now being installed. While much economy can often be secured in reducing loss of power on the line and in first cost by this method as compared with the several methods of boosting direct current, there are certain disadvantages connected with the three-phase system for small roads which ought not to be overlooked, and while local conditions do vary the problem greatly, it is a question whether electrical engineers are not rather prone to install the three-phase system for railway work when the same, or a slightly greater investment in copper would not secure more satisfactory results. The installation in a power station of both continuous and alternating current machinery, with the use of a substation with converting machinery, adds considerably to the variety of types of spare parts which must constantly be kept on hand to avoid a shut-down through accident. This is a more important consideration for a small than for a large road. Again, the depreciation upon this machinery must be equated against the capital investment and compared as well with that on copper wire, which is practically nothing. We, therefore, recommend designers to go carefully over their estimates on the cost of current distribution apparatus, before selecting any particular methods.

It is a well-known fact that the success of an electric railway company depends largely upon the motormen and conductors, and the ability and faithfulness with which they discharge their respective duties. The conductors are the employees most closely brought in contact with the general public, and the opinions formed by the latter of the company are drawn very largely from the treatment received from the men who collect the fares. The motorman, on the other hand, is the engineer of the car, and, especially in crowded streets or where high speeds are attained, his duties require a skill and discretion which are not found in every man of intelligence; in fact, the opinion is growing more and more pronounced that too much care can hardly be expended in selecting the proper men for this important position, or in training them for the proper discharge of the peculiar duties which they have to perform. Emergencies may often arise in a crowded street at any moment which demand the exercise of a high degree of coolness, judgment and a complete knowledge of the operation of the apparatus in their charge, and any defect in one of these qualifications may mean a serious loss to the operating company. While the possession of these qualities is to a certain extent innate, it can also be acquired, and no motorman should consider himself as competent unless he understands exactly the use of the apparatus under his control. By this it is not meant that he should necessarily understand all the electrical connections, or the principles of motor operation, but that he should know, *instinctively*, the exact distance, for example, in which he can stop his car at different speeds by the application of the brakes, the acceleration secured at different positions of the controller handle, the effect of a short circuit, etc. We note with considerable interest that a number of companies have established schools for instructing motormen on the special points on which a good knowledge is desirable. The Metropolitan Street Railway Company of New York, for instance, has fitted up one large room with eighteen or twenty brake-stands, as well as a complete motor truck, fully equipped with controller, brake, sand box, etc., all raised a short distance from the floor, so that the wheels can be revolved and the brakes applied, as in actual service. Around the walls of the room are hung photographs showing the right and wrong ways of applying the brakes, etc., diagrams of the motor connections, and other information which are useful on the road. Regular lectures and talks on the subject of car operation are given by the head of the instruction department, who also explains the proper procedure in case of emergency.

The most admirable thing about the Milwaukee street railway system, which we fully describe and illustrate in this issue, is its conservative financial scheme in which amortization of franchises, depreciation, uninsured losses by fire, accidents, and other contingencies are cared for by special reserve funds to which are passed each month from earnings, predetermined sums. Whenever a company's franchises are limited in tenure, particularly as in the case of Milwaukee, when they expire in so short a time as from twenty-five to thirty years, it is not safe to proceed upon the assumption that they will doubtless be renewed to the present company at the end of the franchise period, but the possible losses to stockholders which may be realized at that time, should be provided for years beforehand by such a reserve fund as that which the Milwaukee Company has wisely established. Depreciation, to which the happy-go-lucky manager shuts his eyes, inevitably forces itself upon his attention, usually at some particularly inconvenient time, by urgent demand for new track, new cars or new motors. The car house, with all its contents, burns down and has to be replaced at a cost twenty-five per cent greater than the insurance money obtained. Is this twenty-five per cent to be taken out of capital, or are the

earnings of the year properly chargeable with it? The theory of these reserves for contingent losses is that the first duty of the manager of any enterprise is to return to those who have invested money in it the principal of their investment, and his last duty is to declare the profits, and these profits should not fluctuate within wide limits from year to year.

The Ford Franchise Bill, even in its amended form, is an example of crude and ill-considered legislation, which is not an honorable part of the record of the State of New York or a credit to Governor Roosevelt, good as his intentions undoubtedly are. To tax as "real estate" that particularly unreal and intangible thing called a "franchise" —a thing whose value is changed every day by the whim of legislatures or councils, by the autocratic decrees of city department heads and tax assessors, by the judicial decisions of the courts, and by the will of the public affecting earning power—is a self-evident absurdity. But this is not the worst error of judgment. The Ford bill is capable of a thousand interpretations and can be put into effect only by the selection of some one method of arriving at the value of franchises from a host of those which may be suggested. The power of making the selection is, by the amendments to the bill just passed at the special session of the legislature called for the purpose, placed in the hands of a state tax commission whose judgment is final, subject only to revision by the courts in equity proceedings. Why was not the method of arriving at the value of these franchises specified in the bill itself and made a part of the statutes? The answer is that neither Governor Roosevelt nor the New York Legislature cared to take the responsibility of suggesting a practicable plan or could do so in the limited time allowed. They, therefore, leave this responsibility with the newly created tax commission without providing, as is usual in such cases, that the commission shall report its plan back to the legislature for final action, but they put in the hands of these few men the right to determine the value of thousands of millions of property. Such a power is far too great and is not in line with our institutions or traditions. By far the safer plan in dealing with interests so large, would be to carry out what is reported to have been Governor Roosevelt's first intention, namely, to refer the whole matter of taxation to a commission formed of the best legal and expert talent in the state and to have guided legislation by their report. As it is, the Ford bill, even in its amended form, is quite likely to be declared unconstitutional, in whole or in part, and the heavy expense to the state of the extra session will be lost, to say nothing of the harm caused by the unsettling of values meanwhile. We have been surprised to see that in the whole course of the discussion in the Legislature and Executive Chamber at Albany so little attention has been paid to the excellent, public spirited work done by the special commision appointed by the Governor of Massachusetts some three or four years ago to investigate the subject of street railway taxation. The plan determined upon by this commission, after a year or more of research, was in most respects sound, legitimate and consistent, far more so than this mongrel legislation fathered by Senator Ford and Governor Roosevelt, which will surely be a thorn in the flesh until amended or repealed.

Financial Analysis of the Brooklyn Rapid Transit System

In view of the many important consolidations which have lately taken place in the street railway system of Brooklyn and vicinity, an accurate statement of the new financial conditions and the possibilities of future development will be of general interest. The following analysis has been made from information furnished by the officers of the Brooklyn Rapid Transit Company for publication in "American Street Railway Investments," the financial supplement to the Street Railway Journal, and is correct to date:

The Brooklyn Rapid Transit Company was chartered in 1896, under the laws of the State of New York, as a successor to the Long Island Traction Company, whose assets were purchased under foreclosure of the collateral trust deed and transferred to the new company. The latter's control of the street railway properties of Brooklyn is through ownership of stock, and the operating agency of the system is the Brooklyn Heights Railroad Company, all of whose stock is in the treasury of the Brooklyn Rapid Transit Company, and to which are leased nearly all the properties originally and recently acquired by the Brooklyn Rapid Transit Company.

The nucleus, and by far the most valuable part of the system is the property of the Brooklyn City Railroad Company, which was leased to the Brooklyn Heights Company, in February, 1893, for a rental equivalent to fixed charges and a dividend of 10 per cent per annum on its capital stock of $12,000,000. About 217 miles, or nearly one-half of the mileage of the entire system, including that in the business district near the East River, most of the approaches to Brooklyn Bridge, the ferries, etc., belong to the Brooklyn City Company. The next largest property in point of mileage (136) is that of the Nassau Electric Railway Company, nearly all of whose stock is now in the treasury of the Brooklyn Rapid Transit Company, and which has just been leased to the Brooklyn Heights Railroad Company. The Brooklyn, Queens County & Suburban Railroad Company, which is a consolidation of three companies previously in independent operation, is owned in its entirety by the Brooklyn Rapid Transit Company, and was leased to the Brooklyn Heights Railroad Company last July. Control of the Brooklyn Union Elevated Railway Company, which is also a consolidation of several other companies, and which has had a somewhat checkered career financially, was acquired in March and April, 1899, and has also been leased to the Brooklyn Heights Railroad Company, and control of the Kings County Elevated Railway Company, the only other elevated railroad property in the city, is now being acquired by the Brooklyn Rapid Transit Company through exchange of stock.

The Brooklyn Rapid Transit Company owns the following securities:

Entire capital stock Brooklyn Heights R. R. Co., which includes equity in 999 year lease of Brooklyn City R. R. Co. to Brooklyn Heights R. R. Co., par value	$200,000
All right, title and interest of the Brooklyn Heights R. R. Co., in the construction account against the Brooklyn City R. R. Co., for extensions and improvements on leased lines, amounting Jan. 31, 1899, to	4,528,503
Entire capital stock, Brooklyn, Queens County & Suburban R. R. Co., par value	2,000,000
Entire capital stock, Sea Beach Ry. Co., par value	650,000
Entire capital stock, Sea View R. R. Co., par value	190,753
First mortgage 6 per cent bonds, Sea View R. R. Co., par value	52,500

84,997.16 shares out of total 85,000 shares of the common stock of the Nassau Electric R. R. Co., par value	8,499,716
60,520 shares out of total 65,000 shares of the 4 per cent cumulative preferred stock of the Nassau Electric R. R. Co., par value	6,052,000
34,713 shares out of total 38,302 shares of the 5 per cent non-cumulative preferred stock of the Brooklyn Union Elevated R. R. Co., par value	3,471,300
109,974 shares out of 129,267 shares of the common stock of the Brooklyn Union Elevated R. R. Co., par value	10,997,400
Entire capital stock of Coney Island & Gravesend Ry. Co. outstanding, par value	35,400
First mortgage 5 per cent bonds, Brooklyn, Queens County & Suburban R. R. Co., par value	*2,000,000
First mortgage 5 per cent bonds, Brooklyn City R. R. Co., par value	*1,627,000
Total	$40,304,571

*Composing guarantee fund for performance of Brooklyn City R. R. Co.'s lease.

The Brooklyn Rapid Transit Company has also acquired through one of its constituent companies, all the property of the former Brooklyn & Brighton Beach Railroad, and has contracted with the Long Island Railroad Company to lease for a period of 999 years certain portions of its line between Brooklyn proper and Coney Island, which can be used to advantage in the new system now being welded together.

The only street railway properties not included in the Brooklyn Rapid Transit system, are the Coney Island & Brooklyn Railroad Company, the Brooklyn City & Newtown Railroad Company, and the Van Brunt Street & Erie Basin Railroad Company. The two first named are valuable properties which may be brought into the system later. They are capitalized at about $5,700,000, and are earning about $960,000 per annum. The last is a small horse railway, 3 miles in length, earning about $30,000 per annum only.

The principal financial characteristics of the consolidated system are shown in the accompanying table in which appears the capital stock and funded debt outstanding and in the hands of the public, excluding that in the treasury of the Brooklyn Rapid Transit Company, which is represented, of course, by its own capitalization, together with the mileage and fixed charges of each company and the gross and net earnings of all the operating companies for the calendar year, 1898. The foot note explains slight inaccuracies in certain of the figures which have, however, no material effect upon results.

It is seen by this table that the entire outstanding capital stock of the system amounts to $59,739,484, equivalent to $121,495 per mile of track, and the funded debt to $48,787,000, equivalent to $99,221 per mile of track; the total capital, therefore, being equivalent to $220,716 per mile of track.

The total earnings of the system from operating and other sources amounted in 1898 to $10,832,642. After paying operating expenses only, excluding taxes, the earnings from operation, applicable to the payment of taxes, guaranteed rentals, fixed charges and dividends on the stock of the Brooklyn Rapid Transit Company, amounted to $3,603,037.

The interest upon the outstanding bonds of the entire system amounts at present to $2,166,730, and the guaranteed rental upon outstanding capital stock of the Brooklyn City Railroad Company to $1,200,000, to which should, strictly speaking, be added a small sum for the pro rata proportion, due upon the small amount of outstanding stocks of the Nassau Electric Railroad Company, and the Brooklyn Union Elevated Railroad Company, for the rental to be paid those companies. The taxes paid in 1898 amount to $379,123. It appears, therefore, that the gross and net earnings for 1898 were not quite sufficient to pay the interest, rentals and taxes of the system, the deficit being $142,816, and nothing was left for the stock of the Brooklyn Rapid Transit Company.

This statement, however, taken by itself, would be grossly unfair to the Brooklyn Rapid Transit system, inasmuch as few of the benefits of consolidation were realized in 1898, and it is also true that they will not come to anything like full fruition until 1900 or 1901. Every effort is being made to get the system into condition to handle a far larger amount of Coney Island traffic than usual this summer, and no doubt the plans are being perfected on a broad and comprehensive scale for the joint operation of the elevated and surface lines to the best advantage of the system in earning capacity. Nevertheless, the electrical equipment of the elevated lines can hardly be fully completed short of two years and the power stations must be given larger capacity for handling increased surface railway traffic as well as elevated. Consequently, as before stated, the full benefits arising from the consolidations of the past eighteen months cannot be realized for two or three years yet to come.

Let us see now what earning power will be necessary in order to make fixed charges and return a 5 per cent dividend upon the Brooklyn Rapid Transit Company's stock. It will not be far out of the way to assume that in 1901 the interest, guaranteed rentals and taxes combined will amount to, at least, $4,000,000, instead of $3,745,853, as at present, since further investment for equipment pur-

poses will doubtless be necessary, and there is a strong probability that the item of taxes will be increased. Adding to these fixed charges a 5 per cent dividend on the $45,000,000 of capital stock, we have $6,250,000 as the required dividend and fixed charge fund of the system. If now we may assume that the system can be operated for 50 per cent of its gross receipts (a far better result, of course, than can be shown at present) the gross receipts must be $12,500,000, while if 55 per cent of the gross receipts be required for operating expenses, the gross receipts must be nearly $14,000,000.

What are the prospects that such a gross earning power can be realized in 1901? The development of traffic in Brooklyn during the past four years will throw some light upon this question. Combining the gross passenger earnings from all sources and the track mileage of all the companies now forming the Brooklyn Rapid Transit system for the years ending June 30, 1895 to 1898 inclusive, we have the result shown in table on page 371.

It will be seen that the percentage increase in earnings from year to year is getting much larger, and that for the year ending Dec. 31, 1898, it is more than 10 per cent larger than for the year ending June 30, 1898. Whether this large proportional increase can be kept up in the next two or three years remains to be seen, but it seems not impossible to hope that this may be the case, and that unless some serious set back occurs, the Brooklyn Rapid Transit system may be earning 4 or 5 per cent on its capital stock in 1901 through the bettering of service, and possibly rates, and the lowering of the percentage of operating expenses to gross receipts.

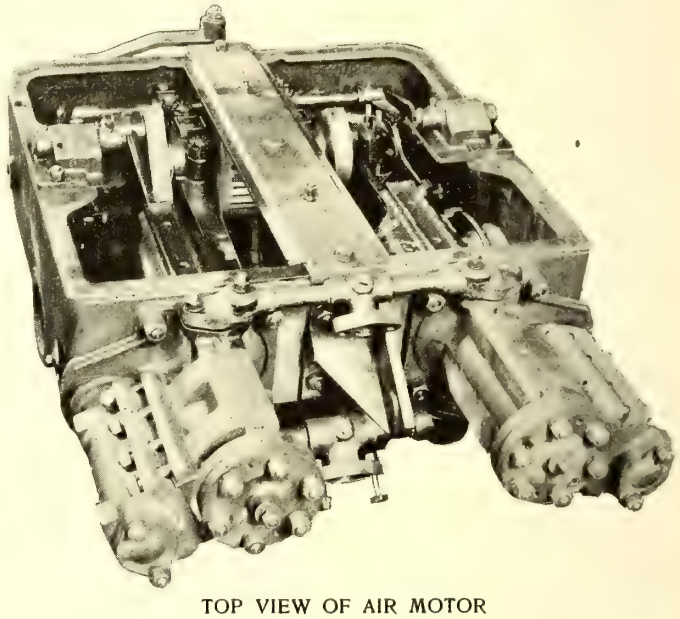
Class Distinctions Cause Trouble

It is a well-known fact that upon many of the tramways of Europe the cars are divided into two compartments, one for first-class passengers and the other for second-class passengers, the rates of fare in the latter case being from two-thirds to one-half of that in the former. In some cases the second-class passengers have no seats provided for them, but stand on the platforms; in other cases, where double-decked cars are used, the upper deck is reserved for the second-class passengers and the lower deck for the first-class; on still other roads the motor car transports the first-class passengers, and is handsomely fitted up, while the trail car carries the second-class passengers, and its decorations are not so elaborate as in the motor car.



A curious effect of this division of passengers occurred recently upon one of the roads in France. In the early morning and late evening hours, when the majority of passengers prefer to ride as second-class, the trail cars became crowded, while the motor cars were so lightly loaded that the latter could not get sufficient traction to draw their loads, and as a result the trains became stalled. After a careful consideration of the problem no remedy could be suggested except that the second-class passengers should be admitted to the motor cars during those hours in which they supplied such a large proportion of persons desiring transportation. This was done, and the difficulty disappeared.

The Consolidated Traction Company, Pittsburgh, Pa., is about to put into regular service an automobile emergency wagon.

Compressed Air Motors in New York

It is well known that compressed air motors are in use abroad on several railways, and in the last issue of the Street Railway Journal some particulars were given of the cost per car mile during 1898 of the motor cars of the Mekarski Compressed Air system upon the line of the General Omnibus Company at Paris. Owing to the development of the trolley system in this country, but little effort has been made up to the present time to give the compressed air system a thorough trial in this country, although a few cars on the Mekarski system were operated several years ago in Toledo, Westfield and other cities.

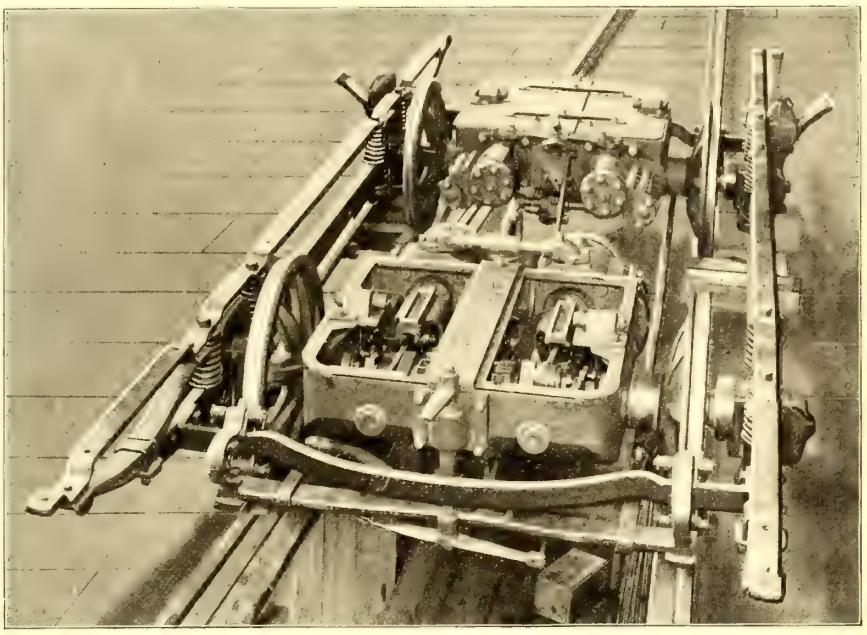
The possibility of developing some system which would operate without overhead wires, however, induced certain prominent capitalists interested in the street railways of New York to look into compressed air as a motive power about three years ago, and to determine whether it might be

TOP VIEW OF AIR MOTOR

made a substitute for the underground conduit electric system and trolley. The preliminary steps taken by this syndicate, which resulted in the construction of an air motor equipment for street cars upon lines entirely different from those which had been followed abroad, are familiar to the readers of the Street Railway Journal, through an article published in these columns in August, 1897, which described the system as then constructed and in use on the Lenox Avenue and Columbus Avenue divisions of the Metropolitan Street Railway Company. Since the publication of that article, the American Air Power Company has been organized, and has acquired all the stock, patents and property of the General Compressed Air Company, the American Air Power Company, of New Jersey, and the Compressed Air Company of New York. This company has been organized with A. A. McLeod as president, Henry A. Humley as secretary and treasurer, and W. H. Knight, engineer, and the following board of directors: A. A. McLeod, W. L. Elkins, Thomas Dolan, Thomas F. Ryan and J. H. Hoadley.

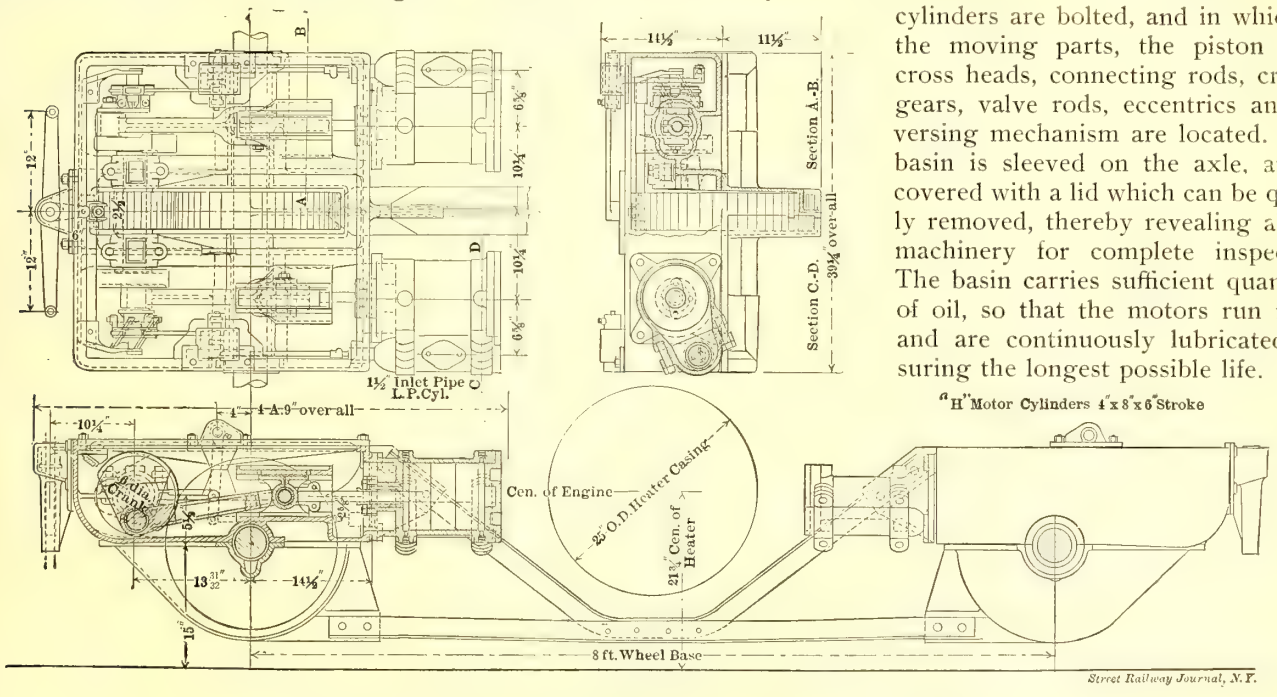
In the meantime, also, important improvements have been introduced in the mechanical features of the system, so that now the company claims an economy of operation closely approximating, if not less than that of the overhead trolley. To determine the actual operating expenses, however, the American Air Power Company has made arrangements with the Metropolitan Street Railway Company to introduce the system on an extensive scale in the

equipment of the Twenty-eighth and Twenty-ninth Street lines of the latter company. These lines are now being relaid with 9-in. girder rail to afford substantial construction for the cars.



In the meantime, the company has built an extensive compressing plant at the western terminal of the Twenty-eighth and Twenty-ninth Streets lines at West Twenty-fourth Street and Twelfth Avenue, containing a 1000 h.p. direct driven, four-stage compressor, with charging outfit and car house to accommodate the equipment necessary for the operation of the Twenty-eighth and Twenty-ninth Streets lines. The capacity of this compressor is eighty cars, and it will operate the Thirty-fourth Street and other cross-town lines as far down town as Bleecker Street. During the completion of the large compressor ten air power cars are performing night service on the Twenty-third Street crosstown line in regular passenger service.

The cars do not differ in exterior appearance in any way from the ordinary underground conduit cars in use on that line. The car body is the same in every particular, and is mounted on a 21 E Brill truck, which carries the air motors. The latter are completely enclosed in a dust-proof case, in which they revolve in oil, lubricating themselves continuously without the attention of an operator. The use of side rods is completely dispensed with, as each axle is driven independently, one by two high-pressure motors, the other by two low-pressure motors. In fact, the principle closely followed in the design of the equipment was to follow the general standard street railway practice as developed on electric roads, the purpose being to retain the use of the standard wheels, axles, trucks and car bodies, as it was thought that these have now reached a form where the expense of maintenance was a minimum.

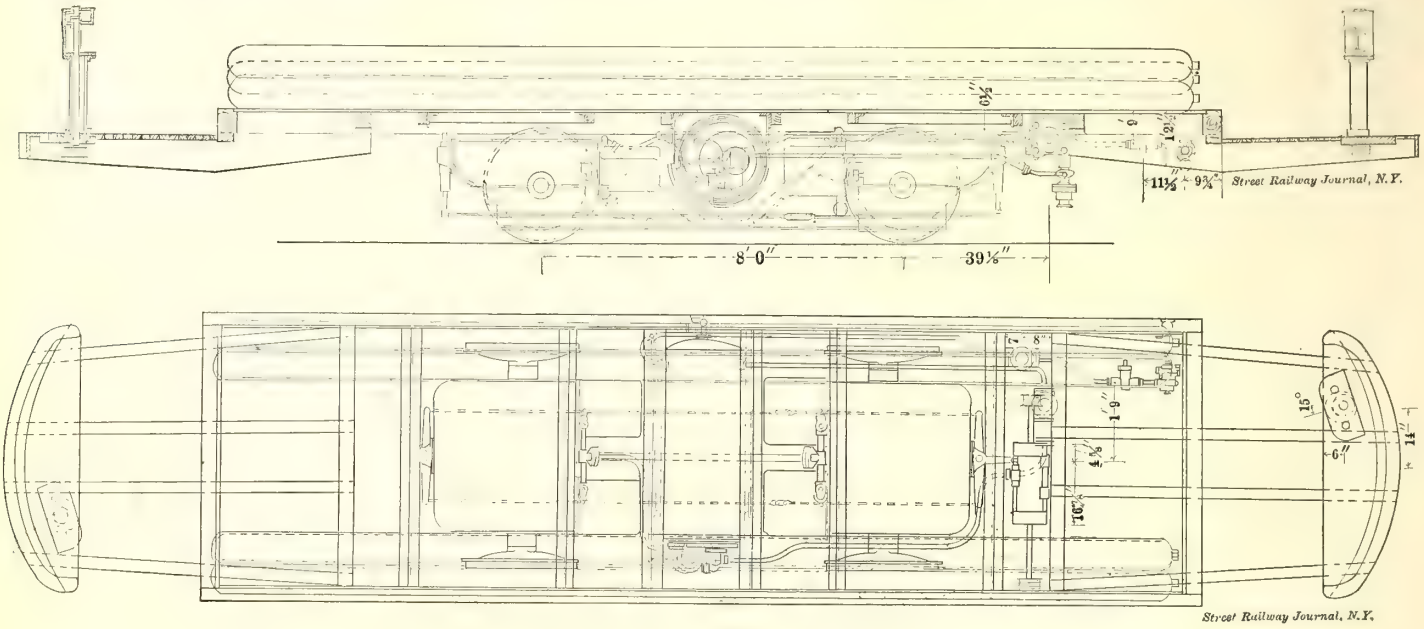


The controller is designed with two handles, one for direction, the other for speed, with duplicate controllers at each end of the car, making it easy for a motorman familiar with an electric power to operate one propelled by compressed air.

The air power system as in use now in New York may be described in detail as follows:

On each axle is mounted an iron clad motor having two cylinders and cranks at right angles. One motor has two high pressure cylinders 4 ins. in diameter and 6-in. stroke. The other motor has two low pressure cylinders 8 ins. in diameter and 6-in. stroke. Upon the crank shaft of these motors is a pinion about 9¼ ins. in diameter, meshing into a 21-in. gear wheel mounted on the middle of the axle. The axle is straight as used for electric motor cars, and the wheels are ordinary street car wheels. The motor consists essentially of a cast iron case or basin, to which the two cylinders are bolted, and in which all the moving parts, the piston rods, cross heads, connecting rods, cranks, gears, valve rods, eccentrics and reversing mechanism are located. The basin is sleeved on the axle, and is covered with a lid which can be quickly removed, thereby revealing all the machinery for complete inspection. The basin carries sufficient quantities of oil, so that the motors run in oil and are continuously lubricated, insuring the longest possible life.

VIEW OF AIR MOTOR TRUCK



PLAN AND CROSS AND LONGITUDINAL SECTIONS OF AIR MOTOR

The air reservoirs, which are seamless steel bottles, are carried under the seats. These flasks measure 21 ft. 6 ins. in length and 2 ft. 5 ins. in circumference outside. There are six on each car. They weigh about 700 lbs. each, and are 9 millimeters thick, and are tested to three times the

pressure they are intended to carry. From these pipes a 1 in. pipe leads to a reducing valve, which reduces the storage pressure to the working pressure. Before reaching the reducing valve, the pipe passes for about 2½ ft. from its length through the heater, so that it can receive sufficient heat to prevent the subsequent freezing of any moisture which may be in it.

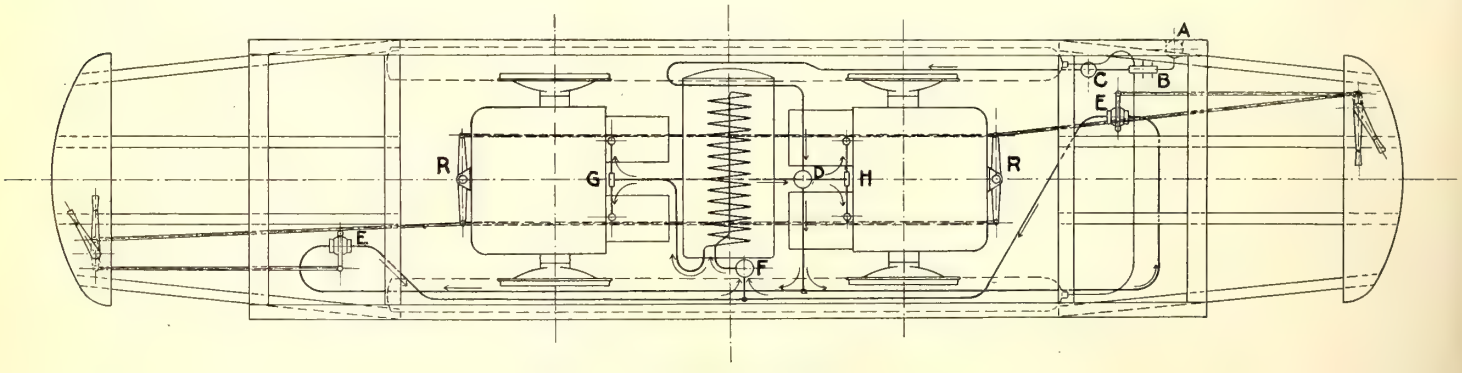
The heater consists of a wrought iron reservoir, that is supported on the cross pieces which connect the two motors, and is charged with hot water under a pressure of about 210 lbs., which corresponds to a temperature of 400 degs. The capacity of the heater is about 60 cu. ft.

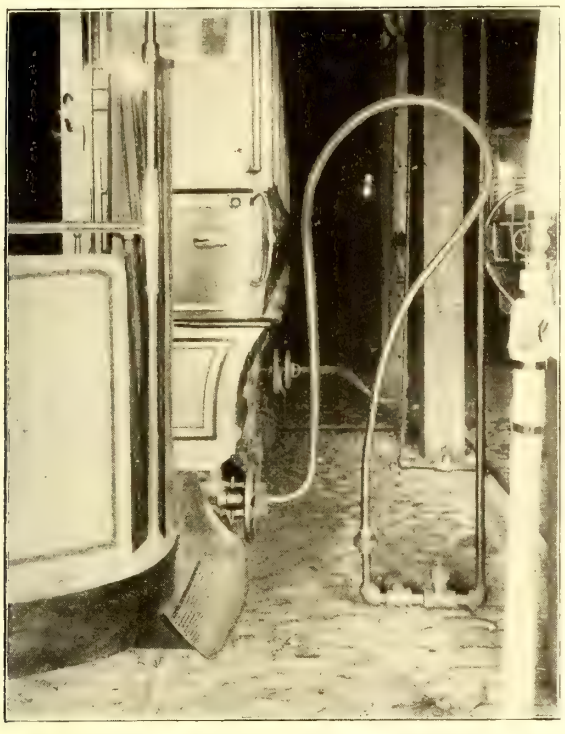
PLAN AND SIDE ELEVATION OF EQUIPMENT

After passing through the heater, where it takes up heat, as described, the air enters the reducing valve, which is of the ordinary type, where its pressure is reduced from 2400 lbs., which is that in the reservoirs, to 320 lbs. From the reducing valve it branches and flows to the throttle valves, one at each end of the car. From the throttle valves it passes to the injector, shown on page 375, where a certain amount of moisture is given to the air. This injector is fed from the heater, and consequently the water is at the same temperature as that in the heater, viz., 400 degs. The moisture not taken up by the air falls to the bottom of the injector chamber, and is led back to the heater. From the injector the air passes through a spiral coil in the heater, consisting of a 1-in. pipe having a linear length of about 50 ft. In this passage it is brought up to the temperature in the heater, so that in the next step, when it is admitted to the high-pressure cylinder, it has a temperature of 400 degs. After exhausting from the high-pressure cylinder, it is carried through a connection underneath the heater to the low-pressure cylinder, and is then exhausted into the atmosphere on the lower side of the low-pressure cylinder through a muffler. By having one motor high pressure and the other low pressure, undue slipping of the wheels is prevented, as when the high-pressure wheels slip the low-pressure motor gets more air and more pressure. On the other hand, when the low-pressure slips its wheel it draws down the pressure in the exhaust of the high-pressure cylinder, correspondingly increasing the strength of the high-pressure motor.

The direction of the flow of the air is shown diagrammatically in the cut below, in which *A* is the charging valve through which the air passes through the head *B* to the bottles, and *B* to the reducing valve *D*. The throttle valves are shown at *E*, the injector at *F*, the connection to the high pressure cylinders at *G* and the connection to the low pressure cylinder at *O*.

In its use of a heater, the practice of the American Air Power Company is similar to that of practically all the other manufacturers of air motors, but, as will be seen, the form of heater adopted is quite different from that which has been used elsewhere. The object of imparting moisture to the air is two-fold; first, it assists in packing the joints, thereby reducing the leakage, as the air would be excessively dry owing to the high temperature to which it is brought. Another advantage of adding the moisture is that during the expansion in the cylinders the water keeps flashing into steam all along the passage as the piston advances beyond the point of cut off. This keeps up the pressure toward the end of the stroke and gives an almost isothermal expansion instead of adiabatic expansion.





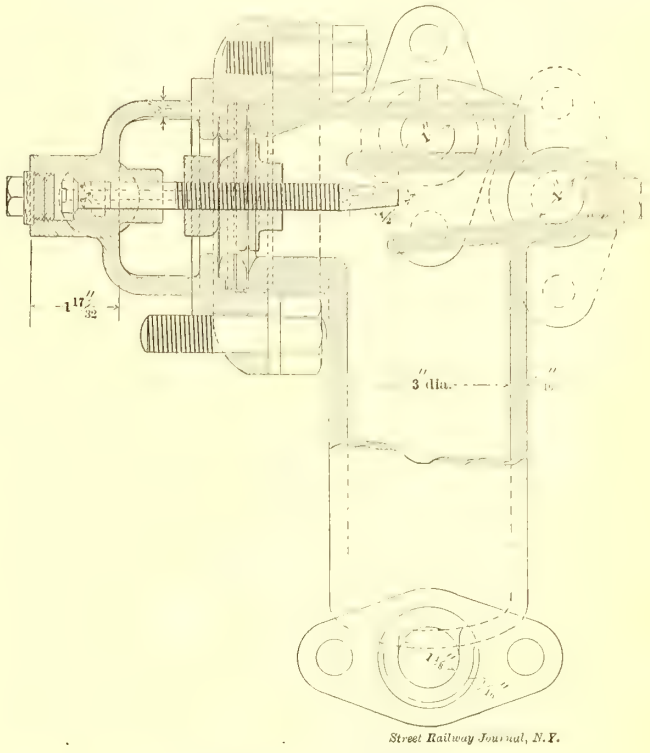


DIAGRAM SHOWING DIRECTION OF AIR

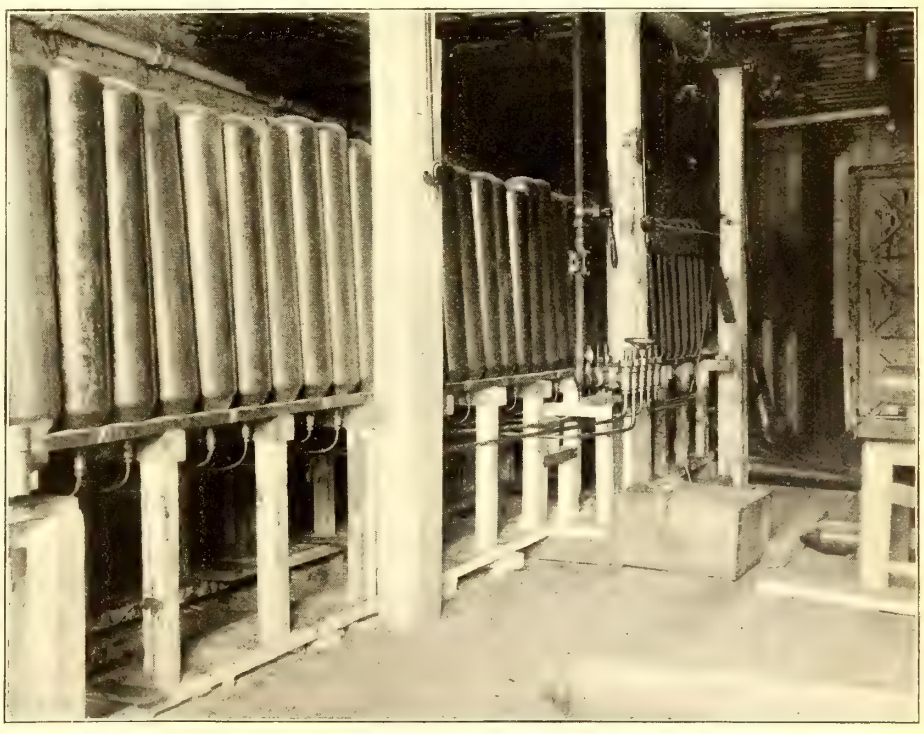
In the heater used on the Mekarski system, to which reference has already been made, the air is made to pass through the hot water; this system was not adopted, first, because the experimental tests conducted with it seemed to indicate that its use was liable to bring excessive quanti-

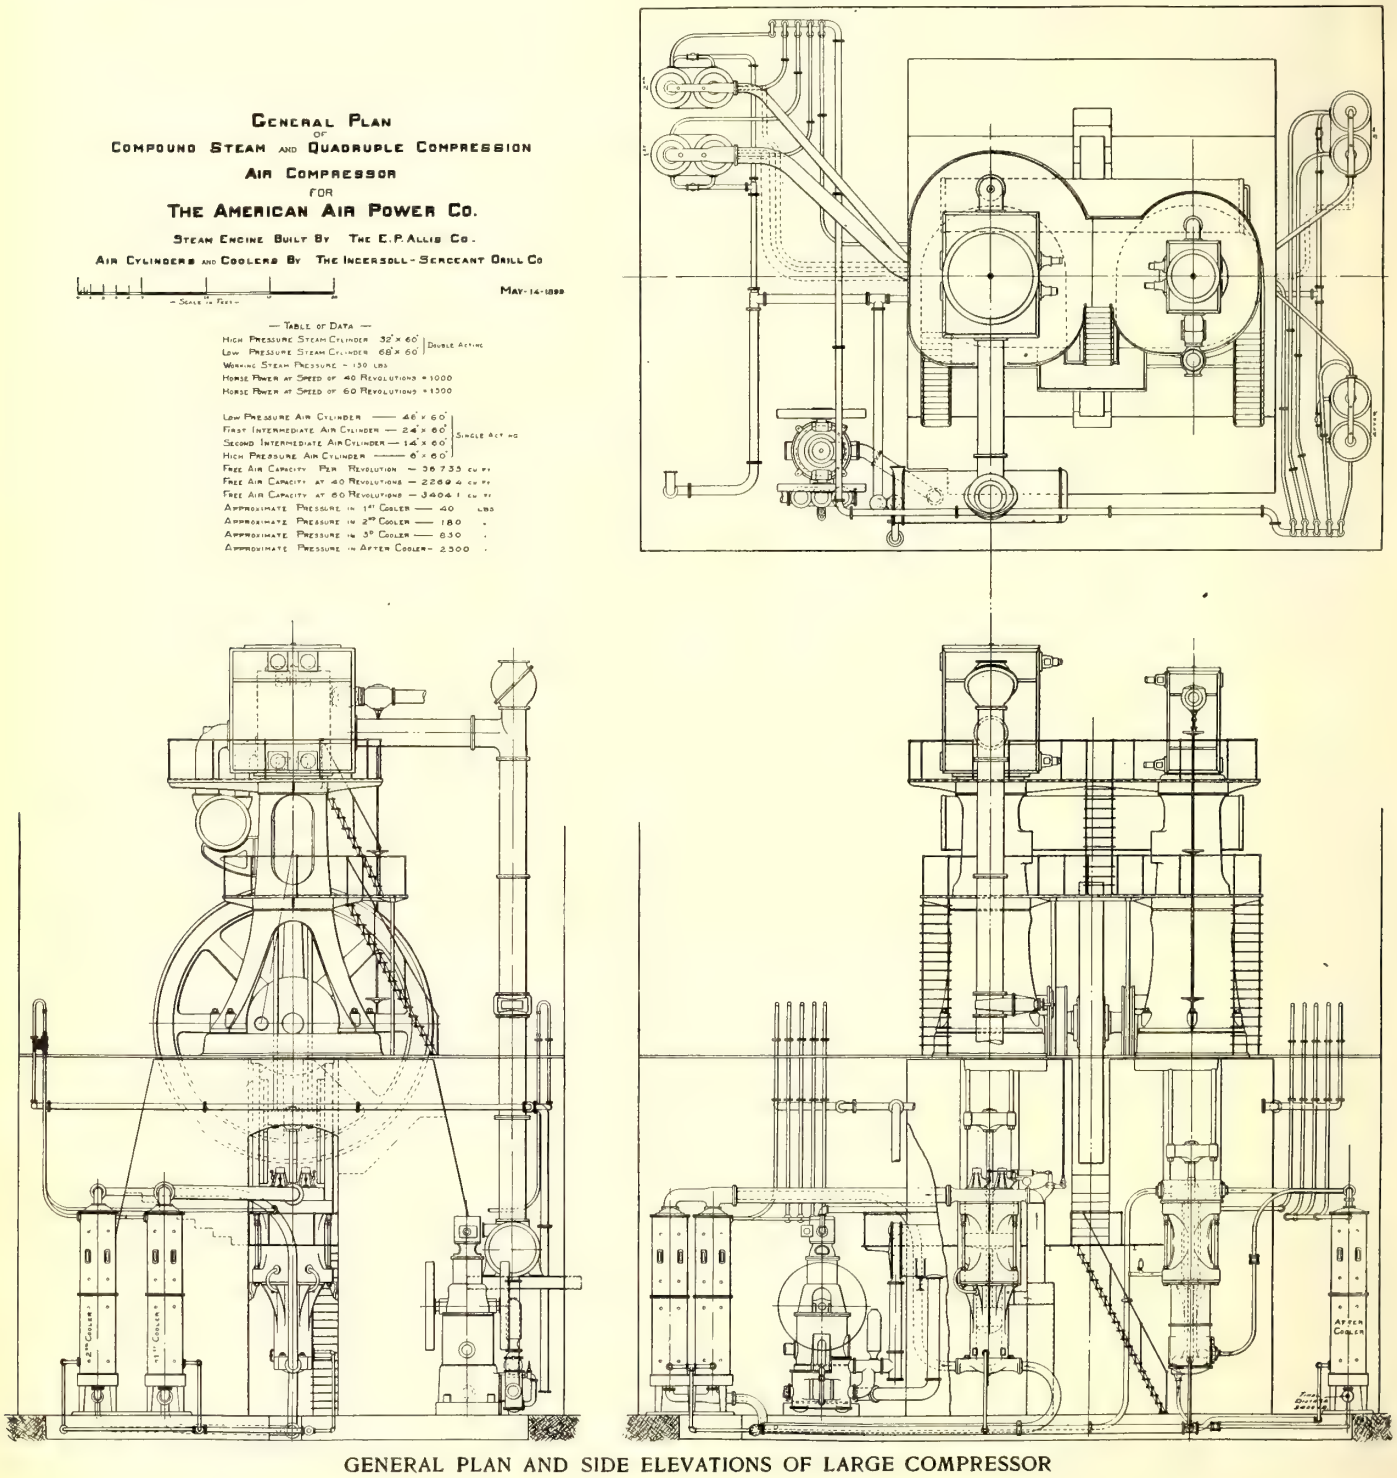


METHOD OF CHARGING CARS

SECTION OF INJECTOR

ties of water over into the motors, and secondly, to reduce the pressure in the heater from that of the air to the 210 lbs. required to maintain the temperature of the water at 400 degs. As will be seen from the sectional view of the injector, the amount of moisture injected into the air can be regulated, while the necessary amount of heat is imparted to the air through its dry passage through the heater.

Two methods of control are adopted, one by varying the cut off, and the other by the use of a throttle. Both methods of control are operated from the platform, which is equipped with a double handle controller, the upper handle being that moving the throttle and the lower that adjusting the cut off. The latter handle has four notches, corresponding to stop, and three degrees of speed. On the first notch the valve is set to cut off at one-quarter stroke, the second stop at one-third stroke, and the third notch at five-eighths the length of the stroke. At the neutral position the air pressure is entirely cut off, and as the motor cylinders are fitted with check valves, the car can coast without creating any back pressure or vacuum. The usual position of the cut off when the car is in operation is that of the first, or one-quarter, notch, which is, of course, the most economical point of running. The speed is then controlled by the throttle. Should the motorman desire more power or higher speed than can be given with the throttle open, the cut off can be advanced to one-third or five-eighths point, and to avoid accident the motors can be reversed if necessary, by throwing the cut off controlling handle around to the reversing position without touching the throttle, although this brings a strain upon the motors similar to that experienced by electric motors when suddenly reversed. No special notches are provided on the reversing side of the cut off controller disc, as they would be little used. When the car reaches the terminal of its route, the two controller handles are lifted off the spindles and carried to the other end of the car, as with electric operation.



VIEW IN STORAGE ROOM

The results secured during the past two years have dem-

onstrated that the motors are highly efficient and exceedingly durable, all the original parts being still in use. The manufacturers estimate that making a liberal allowance for the wear which must occur, and which, in the case of the more rapidly wearing parts has been measured, the maintenance per car mile will compare favorably with that of an electrical equipment.

ble of slipping the wheels on a dry rail under a weight of 30,000 lbs., corresponding to that of a powerful electric motor equipment, with which, as will be seen, it does not differ materially in weight.

Several sample indicator diagrams, taken from the high and low pressure cylinders, are given on page 378. As will be noticed, they are similar to locomotive diagrams,

GENERAL PLAN AND SIDE ELEVATIONS OF LARGE COMPRESSOR

The weight of the standard car as in use on the Twenty-eighth and Twenty-ninth Streets lines is as follows:

Car body	6000 lbs.
Trucks	4500 "
Air reservoirs	4200 "
Heater	700 "
Motors (each 1400 lbs.)	2800 "
Controlling apparatus and other fittings	400 "
Piping	150 "
Total	18,750 lbs.

The motors upon which this estimate is based are capa-

and have the characteristics of diagrams taken from cylinders with link type of cut off.

Reviewing briefly now the motor equipment, it will be seen that the system differs in many respects from that used abroad, notably (*a*), in the form of motors employed, (*b*) in the method of heating, and (*c*) in the high pressure used. The adoption of a pressure of 2400 lbs. in the reservoirs was to increase their capacity. As at present designed, the cars can run 15 miles on a trip with a charge that is restricted to a space under the seats, and this can be increased to 20, 30 or 40 miles by crowding in all the

flasks that the space would allow, or by increasing the pressure, as the company is now preparing to do. As the reservoirs have a capacity for withstanding three times the pressure used in them, it will be readily seen that the element of danger is practically eliminated. There is no deteriorating influence on the reservoirs incident to the use of this pressure, nor has there been any explosion with any of the flasks by air except when premeditated, and only then with the greatest difficulty and with apparatus specially constructed to bring the required force into play.

The cars operate noticably without noise, and start noticeably without jar and with a cushioned effect which is extremely easy for passengers.

The method of charging is another feature to which the engineers of the company have devoted a great deal of attention, and which is now accomplished in a minimum space of time. A general view of the main charging room is shown on page 375. The main charging reservoir consists of a large number of the same type of flasks as used on the car, but carried in a rack and piped to a manifold, from which the air from the compressor is switched into any bank of reservoirs desired. From this point the air under pressure is piped to the charging room, where are located the charging nozzles. The latter are carried upon a flexible goose neck so arranged that the nozzles can be readily fitted to the charging valve. Adjoining the air charging nozzle, but located in such a position that it will come opposite to the heater, is the hot water charging nozzle, which is similar in general appearance to that used for charging the air reservoirs. This device has a double set of pipes, one for introducing the hot water into the reservoir, and the other to allow the discharge of the water which may be in the heater after a run. The process of charging the air reservoir, hot water reservoir and removing the cooled water can be accomplished simultaneously and in a short space of time.

The compressor plant, which has just been completed at the corner of Twelfth Avenue and Twenty-fourth Street, by the Ingersoll-Sergent Drill Company, is unusual in almost all of its features, but especially in two points, its great power and the high pressure obtained. High pressures with smaller machines are common, but pressures of 2400 lbs. to the square inch in 1000-h.p. machines are essentially unique.

In general the machine consists of a vertical cross compound engine, built by the E. P. Allis Company, of Milwaukee, which has cylinders 32 ins. and 68 ins. x 60 ins. stroke, and is provided with Reynolds Corliss valve gear.

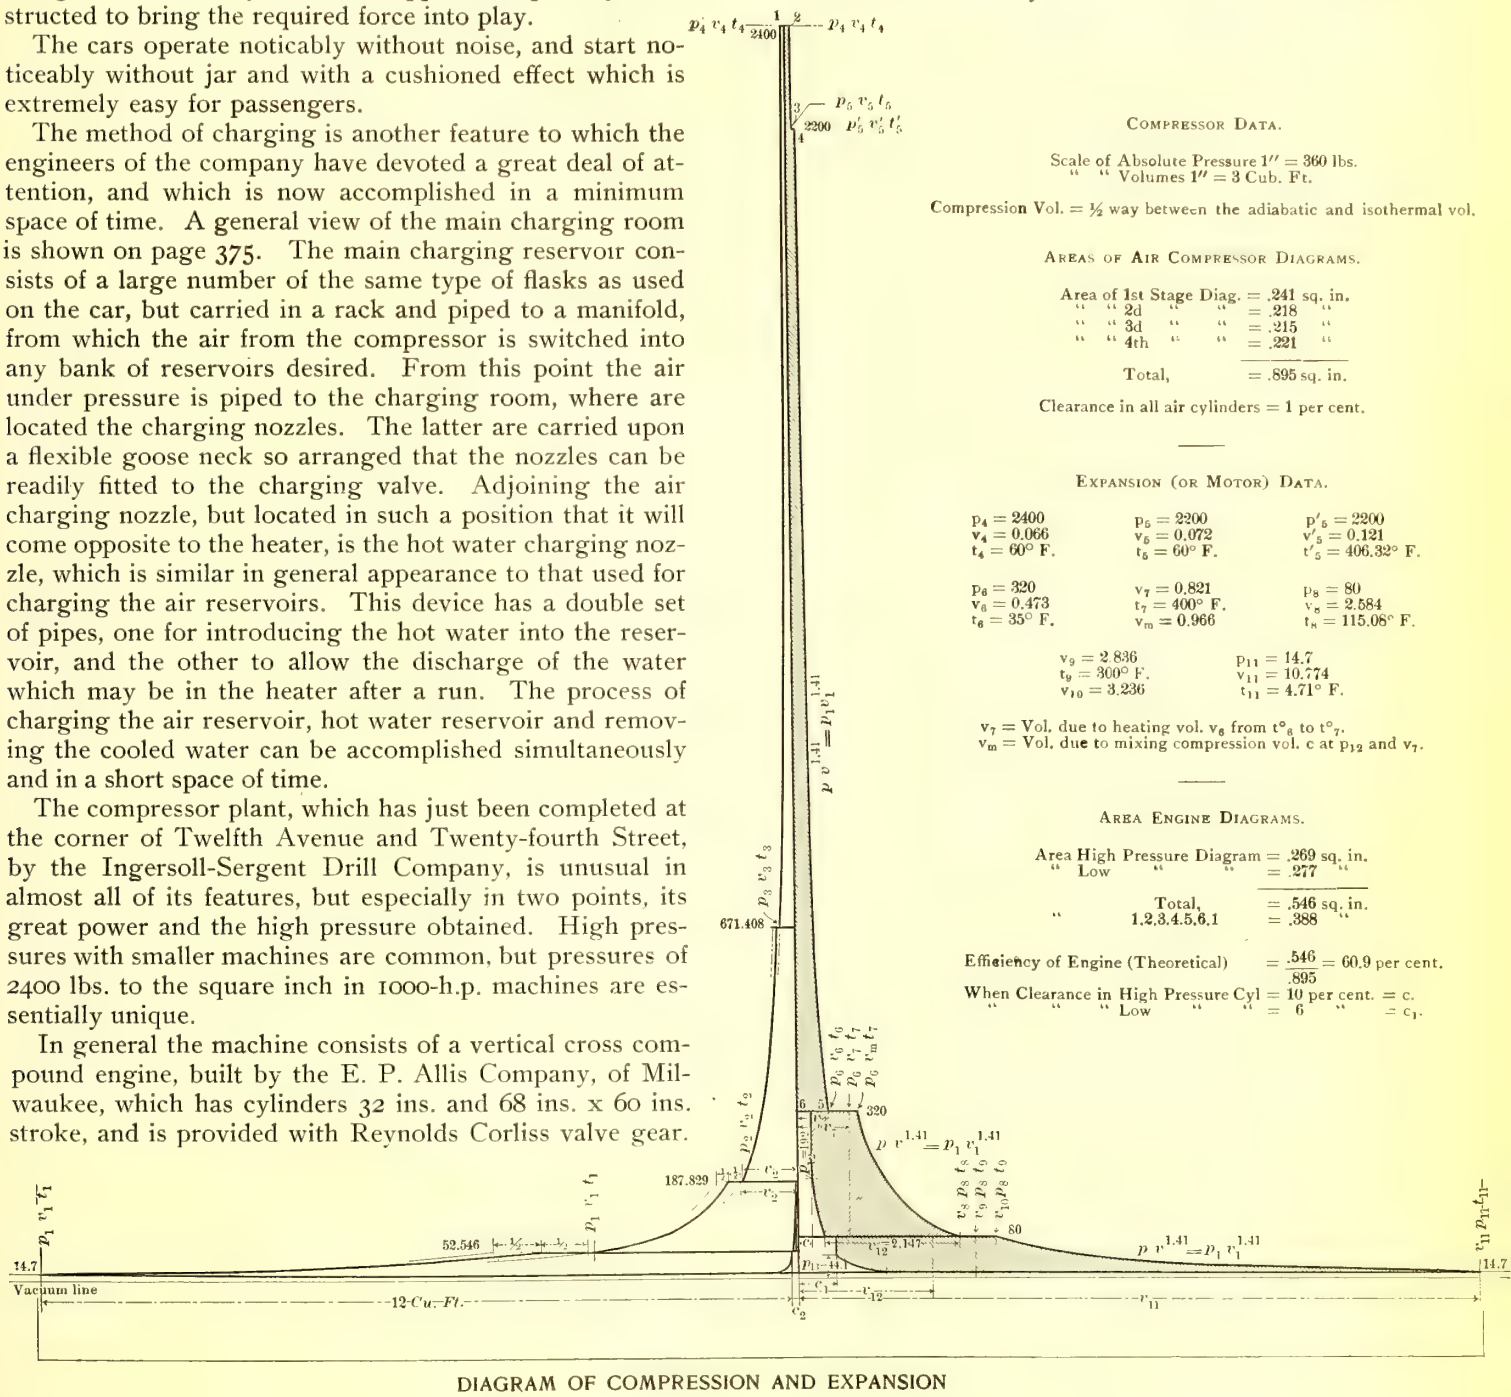


DIAGRAM OF COMPRESSION AND EXPANSION

With steam pressure of 150 lbs., furnished by Babcock & Wilcox boilers, 40 r.p.m., and most economical point of cut off, the horse power is 1000. The shaft is of hammered iron 22 ins. in diameter outside of the journals and 20 ins. diameter in the bearings which are 36 ins. long. The fly wheel, placed between the cylinders, is 22 ft. in diameter and weighs 60 tons. The engine is mounted upon brick piers, and directly underneath it is placed the air compressor.

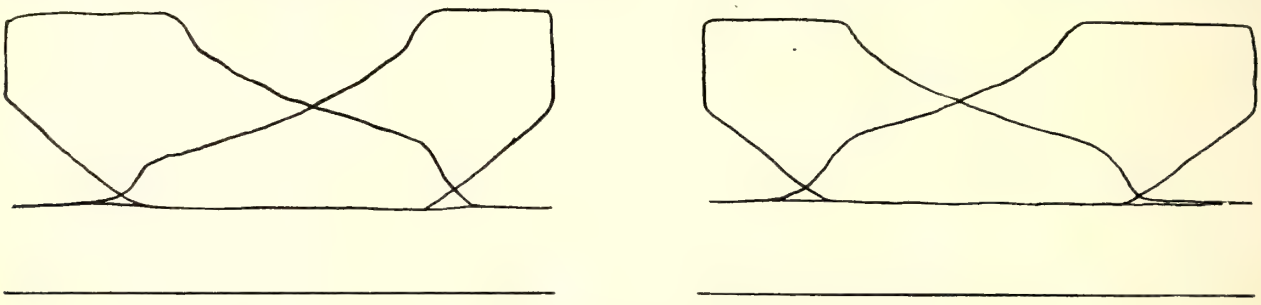
This machine is of the four-cylinder type, the low pressure cylinder being 46 ins., the first intermediate 24 ins., the second intermediate 14 ins., and the high pressure cylinder 6 ins. in diameter. The stroke being common with that of the engine is 60 ins. All of these cylinders are single acting and are water-jacketed. The free air capacity per revolution is 56.735 cu. ft.; capacity at 40 r.p.m., 2269.4 cu. ft., and the free air capacity at 60 r.p.m. is 3404.1 cu. ft. The approximate pressures in the different coolers are given in the large diagram showing cycle of operation.

The compressor pistons are arranged in pairs vertically in line beneath the steam cylinders as is shown in side and end elevations. The initial and first intermediate air cylinder being below the low pressure steam cylinder, while the second intermediate and high pressure air cylinders are below the high pressure steam cylinder. Motion is transmitted from the steam engine cross heads through distance rods, one pair for each crosshead, to a crosshead attached to the air cylinder piston rods.

The intercoolers employed are of two different designs. The two for the lower pressures consist each of a shell inclosing a nest of vertically arranged cooling pipes, through which the air passes going from one cylinder to the other. The coolers for the higher pressures consist each of a shell

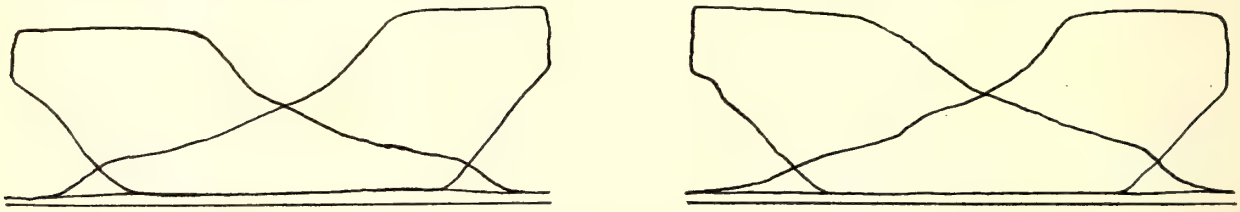
inclosing a pipe coil. The former construction was adopted for the lower pressures because great cooling surface was required on account of the large volume of air, but in dealing with the higher pressures coils were substituted so as to dispense with as many joints as possible. The coolers are arranged so that in case of leakage of air from the cooling pipes into the shell or casing this air will rise with the circulating water up to the operating floor of the engine room and discharge through a slight discharge pipe under the immediate care of the engineer. All the piping from the first air cylinder and through the entire compressing plant is of copper.

What may be called an auxiliary governor controlled by air pressure is provided to act upon the governor of the steam engine. This consists of a weighted lever which is operated upon by a small piston, which in turn is actuated by the air pressure. If for any reason the pressure should become excessive, the lever is lifted. This opens a valve admitting air to a device on the governor, so designed as to reduce the steam supply and for all practical purposes, to throttle the engine.



Some idea of the massiveness of the machine may be obtained from the bare statement that it is 60 ft. in height. It will be employed exclusively for supplying air to the air motor cars on the street railway cars.

The water used for cooling the air in the intercoolers is taken from the North River, which is a few hundred feet from the station, through a 16 in. water main. After passing through the intercoolers this water is discharged into the river through a second 16-in. main.



Referring now particularly to the diagram given on the previous page, showing the cycle of compression and expansion, this diagram is drawn to scale, the abscissæ representing volumes, and the ordinates pressures. The left hand side of the diagram shows the compression curve, and the right hand side the expansion curve. Twelve cubic feet of air is taken as a basis, the scale of pressures being 1 in. to 3 cu. ft. The curve of actual compression in each cylinder of the compressor is considered to be half way between the theoretical adiabatic and isothermal curves on account of the water jacketing, and at the end of each stage of compression the air is brought back to the corresponding point on the isothermal curve through the cooling of the air in the intercoolers. Short arcs of the true isothermal and adiabatic curves are given on the diagram at the end of each stage of compression.

The portion of the curve to the right hand of the center line shows the pressures and volumes at each stage of expansion. The actual values of pressure, volume and temperature at the end of each stage are shown by $p_4\ v_4\ t_4$, $p_5\ v_5\ t_5 \ldots p_{11}\ v_{11}\ t_{11}$. The effect of heating the air is shown in the differences between $v_5\ t_5$ and $v'_5\ t'_5$, and again between $v_6\ t_6$ and $v_7\ t_7$. The effect of the injection of moisture is shown in the difference between v_7 and v_m.

The theoretical efficiency of the entire mechanical cycle can, of course, be obtained by dividing that portion of the area of the right hand curve, which represents work performed, i. e., that of the high pressure and low pressure diagrams, by the entire area of the left hand curve. According to these figures, the theoretical efficiency of the cycle is 60.9 per cent. This figure, however, is, of course, slightly in excess of the true efficiency of the entire system on account of the addition of heat from the hot water heater. The effect of subtracting this, however, will not materially affect the total efficiency, as given above.

SAMPLE INDICATOR DIAGRAMS FROM HIGH PRESSURE CYLINDER OF MOTOR

SAMPLE INDICATOR DIAGRAMS FROM LOW PRESSURE CYLINDER OF MOTOR

The question of air consumption and cost is, of course, an important one. Upon this point the company hopes to be able to contribute some important data soon. From tests already made, however, Mr. Knight, chief engineer of the company, states that the average consumption per car mile has been 450 cu. ft. of air, and the cost per car mile has been about $.025.

The writer has found the following system of repainting cars to be quite satisfactory: First remove all old paint by softening it with a blow-pot just enough to allow it to be scraped off with a broad putty knife, not allowing the flame from the blow-torch to strike the bare wood at any time. Then sand off the surface well with block and sand paper. Where any new work has been put in, it should be first primed with a coat of boiled oil and a little lead and allowed to stand for not less than four days. Dashes and all iron-work should be thoroughly cleaned with strong alkali and primed with a coat of linseed oil, put on boiling hot and allowed to thoroughly harden, giving one coat of oil and lead before color. If the surface is rough, plaster with lead on this coat. Then allow it to thoroughly harden, and sand with block; then lay on two coats of flat lead, two coats of color, color varnish, stripe and ornament, finish with one coat of rubbing varnish and one coat of finishing varnish. From paper at the Boston Convention, 1898.

Street Railway Parks

MIDDLETOWN, CONN.

The Middletown Street Railway Company serves an elaborate park located 2½ miles from the center of that city, which has a population of about 15,000, the total population served by the street railway system being about 20,000. The park contains about 20 acres of land, one-half of which is well covered with shade trees. It has been left in its original state as much as possible, and this fact contributes very largely to its popularity among lovers of rustic beauty. A deep ravine, over which a rustic bridge has been constructed, runs through the grounds. Although the natural features of the place have been carefully preserved, a large amount of money has been expended in improvements and in providing the usual attrac-

VIEWS IN PARK AT MIDDLETOWN, CONN.

tions for resorts of this kind. A rustic theater, having a stage 30 ft. x 50 ft., and situated at the foot of a hill, which is covered with a hemlock grove, is one of the most popular institutions. The stage was made extra large to enable it to be used for dancing after the shows are over, but dancing accommodations have not been found profitable. In front of the stage and on the slope of the hill are located some 400 seats, for which a charge of five and ten cents is made during the performances. The ten-cent seats are quite comfortable; the five-cent ones being ordinary chairs fastened together.

A large lake in the park adds greatly to its popularity. One section of the grounds, well shaded, is reserved for the use of picnic parties, so that churches and societies can have exclusive privileges for their outings, at the same time being able to avail themselves of all the advantages of the park. A small-sized restaurant building and a flying-horse merry-go-round are among the most recent attractions installed.

E. W. Goss, superintendent of the Middletown Street Railway Company, has the following to say in regard to street railway parks: "As far as our experience with running a park is concerned, as we have only had one year in which to judge, it is hard to form an opinion. Last season, after we commenced running the park, we handled heavy crowds, a large number of which were pleasure-seekers exclusively. We did not make any charge for admission to the grounds, depending for our remuneration upon the increased traffic on our cars and upon the money spent by visitors in seeing the entertainments. We think it would cost more to collect an admission charge at the gates from non-patrons of the cars than we would take in by so doing. We do not allow bicycles or teams on the grounds, wheels being checked at a small building near the entrance, and posts being provided outside the park for hitching horses. The park will be opened on June 19, and the theater entertainments will consist of the usual vaudeville attractions."

PADUCAH, KY.

Paducah has a population of 25,000, and there are no public parks, so that the park of the Paducah Street Railway Company forms the only outing grounds for the people. These grounds contain 75 acres, of which about 20 acres are now used for park purposes. The resort is located some 2 miles from the center of the town.

The value of the park is placed at about $50,000, and nearly $17,500 have been expended in improvements, as follows: Erecting a handsome brick building, which is occupied by the park keeper, who boards the actors in summer, $5,000; constructing summer theater, $2,500; total for improvements on grounds, $10,000. The park contains a lake covering about 5 acres, and supplied from the city water mains. Here bathing house, boats, etc., are provided.

George C. Wallace, general manager of the Paducah Street Railway Company, writes as follows:

"In our theater we have tried both stock companies and vaudeville shows, but find that a good stock company, with specialties once a week, and a good band are the best drawing cards. We also give balloon ascensions, fireworks and lake displays, for which we charge admission to the park. At other times admission to the grounds is free, and a small charge of five or ten cents is made for seats in the theater. We also keep a few animals, such as bears, monkeys, etc. We now lease the amusement features for a nominal sum. We have from 500 to 1000 people in attendance each night, and from 2000 to 5000 at the other attractions.

"Our season opens May 15 and closes Sept. 15. On account of our long, hot summer we find the park quite a paying investment."

SCHENECTADY, N. Y.

H. S. Cooper, superintendent of the Schenectady Railway Company, in reply to an inquiry regarding the recent improvements made in the pleasure park of his company, writes as follows:

"We still run our pleasure park as an 'assembly ground,' and find no reason as yet to change its character to an 'amusement park,' and do not believe that we could at the present time make it pay as such.

"We have already booked nearly every Saturday of the season, together with several other days, for picnics, 'field days,' etc., of the various societies and organizations of the city. The revenue from these, together with the returns from the sale of privileges, admittance to evening dances, hiring of boats, swings, etc., will go well towards paying fixed charges and operating expenses, leaving the extra traffic engendered by the park as nearly clean profit.

"We have made no large improvements, but are all the time adding any small thing that will increase the park's comfort, beauty and convenience.

"We will, this winter, try skating, hockey and curling rinks, so as to see if we can lessen the 'dead time' of the park, and add a little to our winter traffic. We shall try it carefully and conservatively, but thoroughly, and hope to be able to report a success.

"Specifically answering your question as to the value of parks, we can say that it has been our experience that our park has been a profitable enterprise to the railway company. It has been made so by fully studying our people here, their needs and desires, and by cautiously catering to them in all things that were profitable, and not by blindly following the lead of 'any old place,' and rushing into expensive and unremunerative 'attractions.' We may come to 'attractions' later on, when we find that our present course shows signs of failing to pay, or be popular; and we will then have the experience of others to aid us in knowing what NOT to do, and with our park in its present course shows signs of failing to pay or be popustart anything we may wish, and without the extraordinary initial expenses and mistakes of an absolutely new and untried enterprise."

Summer Park Theaters

BY J. W. GORMAN

Park amusements in connection with street railway pleasure resorts have now developed to such proportions as traffic producers, as to warrant the most careful consideration of managers and directors everywhere. The progressive and up-to-date management of any corporation or institution is the one, of course, that is constantly studying out new methods of increasing and extending the business and revenue earning capacity of the plants under their control, and in no case does this apply with greater force than in the matter of adding summer parks and amusement features to already well equipped street railway systems for the purpose of adding to the regular, necessary and business patronage a purely pleasure traffic. Two features predominate in the life of every city, viz., business and pleasure, otherwise there would be but bare walls and business structures, grim stores, banks and markets, instead of, as now, attractive shops and windows, handsome residences, amusement halls and brightness in all things, as an expression of the tastes, likes and wishes of the dwellers. The far-seeing and progressive street railway manager takes advantage of these two characteristics, and while paying strict attention to the regular and what may be called the legitimate traffic on his road—at the same time increases his earnings by catering to the love for pleasure and recreation among the people his system serves.

A properly conducted park situated from 3 to 10 miles from a city and provided with proper amusement attractions, gives the incentive for a ride on the electric cars—the ride in itself bringing relaxation from the day's business cares, while the attraction to be witnessed acts as an additional inducement.

The writer, as the result of careful observation and inquiry, estimates that during the average weeks of summer, a traffic equal to the entire population of the city can be induced by a properly conducted amusement adjunct to a traction company. In illustration the following remark is given, made by the progressive and successful manager of a once non-paying and "run down road," who had revised all former methods, and added a handsome park. In conversation with a prominent manager of summer attractions, this gentleman said: "Mr. ——, our road paid you last week $400 for your amusement company, and we carried 45,000 paid fares to our park during the week. The population of our city is 48,000, so undoubtedly many witnessed the performance more than once. We do not hesitate to tell you this, * * * and your contract with us is a fixed one." The writer relates another instance in which a manager stated that during the entire amusement season his road had averaged 20,000 paid fares per week from the park travel, the city having a population of but 22,000 people.

The manager of a traction company who sends out letters and circulars or makes efforts to induce circuses or menageries to visit his city and to locate their places of exhibition on his line, is another example of up-to-date management.

The prevailing error that is being made by roads with handsome and suitable parks is in giving the cheap and mediocre entertainments easily obtainable, arguing that, "it is all free and the quality does not matter." Here lies the error of otherwise shrewd business men in catering to the masses. Now, is the show free? Does the public not pay for the exhibition? To convince any traction company, it need but to thoroughly advertise that its cars will start at a certain hour and day for such a park with no performance mentioned. There will be no unusual life, interest or fares taken. Announce as thoroughly that there will be presented a known and desirable attraction that has a reputation and drawing power at the local city Opera House in the regular season, and that there will be no charge for the performance, and the capacity of the cars will be crowded to the utmost. Do not the riders pay for the show? Certainly they do, and the fares are collected not for the ride alone, but in conjunction with the attraction.

The performance must be good and well conducted. The talent must be of merit to win the praise of intelligent people, and adapted to the wants and wishes of each city for the best results. This selection must come from experience. An evening's time to citizens is too valuable to be thrown away that some irresponsible talent may be presented, and some irresponsible "hawker" of amusement wares and goods may make a handling commission or profit. The right men can be found to provide desirable and worthy entertainments in line with good taste, and morality acceptable to church attending patrons, as well as to the general public. Nor should traction companies limit their amusements amount to such a low figure that good talent cannot be employed. Many a park that loses money at a small figure for attractions would make large profits if double the amount was expended for attractions of drawing power and of sterling merit and reputation.

The traction companies in the East have developed much beyond those in the West and Middle States, in availing themselves of the great revenue that comes from the pleasure seeking public, but there is little doubt that at no distant day, nearly every progressive street railway system in the country will have its summer park and open air theater presenting meritorious attractions as established adjuncts to its general business.

The Electrical Installation Company, Monadnock Block, Chicago, has just closed a contract for the complete rehabilitation of the Vicksburg (Miss.) electric lighting system. Work will be started immediately, and rushed to completion within ninety days.

LEGAL NOTES AND COMMENTS*

Edited by J. Aspinwall Hodge Jr., and Robert Ernest, of the New York Bar

Taxation of Franchises

The last few weeks have been prolific in the discussion of this topic in New York, owing to the introduction and passage, as the result of an emergency message of the Governor, presented to the Legislature last March, of what is known as the Ford Franchise bill, and as we go to press an extra session called by the Governor has passed amendments which he deems necessary. The original bill consisted of less than a dozen lines to be inserted in subdivision 3 of section 2 of the Tax Law of the State, which section defined the terms "land," "real estate," and "real property" as used in that chapter. The tax law provided that real estate should include, among other things, all surface, underground and elevated railroads, and also the pipes laid in and above any public or private street for the purpose of conveying water, oil and other substances or products, and the Ford bill inserted after the words "railroads" and "pipes" the words "the value of all franchises, rights, authority or permission to construct, maintain or operate the same" through streets, highways and public places.

This bill was held by some, and notably by two of the leading morning papers, as a radical measure of great importance, making an epoch in the history of taxation in the State and imposing upon corporations their just proportion of the burden of taxation which heretofore, it is asserted, they had not borne.

Another portion of the public, who found representation in another of the leading morning papers, talked and wrote against it in the strongest terms, alleging that it imposed double taxation upon corporations and was a socialistic attack upon wealth.

A third view was taken and seems still to be held by many to the effect that the law is of little importance, and that it practically imposes no new burden; that the amount of tax to be derived from it, instead of being very large, will be very small; and that, as a matter of fact, it is merely declaratory of the present law.

The laymen and, we have suspicion also, the Governor himself (certainly when the law was first drafted and passed), have had confused notions and inadequate ideas of the scope of the act and its effect.

This effect can only be determined by a careful examination of the decisions of last resort of our own State, with some side light thrown upon the matter by the decisions of the courts of other States where similar enactments have been pased. These decisions will only afford light when one has clear and definite ideas of what a franchise is, or of what taxes are already laid upon franchises in New York. Without quoting authorities, it is manifest that the franchise referred to is not what is often called a "corporate franchise," which is the right of several individuals to be and become a corporation, but it is that right possessed by a corporation or by an individual (for, as a matter of fact, the Ford bill applies to individuals who have such rights, as well as to corporations) to maintain and operate mains, pipes, conduits or wires for transporting certain products or substances, including electricity, or to maintain and operate railroads through streets and highways.

Were it not for some decisions in the State, it might be contended with some show of reason that the Ford amendments do not change the tax law, for manifestly if the assessor is to determine under the old law the value of a gas pipe in a street, it would be contendable, if not reasonable, to hold that in determining the value of the pipe laid below the surface of the street, the right to have it there should be included. Its value as a pipe, without the right to leave it where it is and to put gas through it, would be its value as old iron; or certainly not more than the cost of putting it there. One might even go so far as to hold that it is worth less than nothing since, without the right to leave it in the street, it would cost more to take it away than the value of the pipe.

But if the assessor places the value upon the pipe as a usable article in the street, in other words, adds to the value of the pipe, the value to use it (without which few articles would have real value at all), then manifestly the original Ford bill would not change the law one iota, nor would the amendments presented by the Governor in his message calling a special session of the Legislature, except so far as those amendments placed the assessing of the value in the hands of the State, instead of the local authorities, and make some provision against double taxation.

The impossibility of separating the value of the pipe and the value of its use is evidenced by the fact that in the amendments proposed, these two are included in one item, and by particular definition are dubbed a "special franchise," the value of which is to be ascertained by the State Board of Assessors.

But the original Ford bill does change the law, because the courts have construed the tax law as it was before the passage of the bill to mean that the mains and pipes of the gas company may be taxed, but not the privilege granted by the local authorities to use them. (*People ex rel. Keystone Gas Co. vs. Martin, 48 Hun, 193*). The decisions of the court maintaining this proposition, the Ford bill necessarily makes as a change in the law:

All corporations, under other provisions of the tax law, are taxed upon their capital stock to an amount determined by its value, arbitrary values being fixed upon stock paying specified dividends. This tax is often called a franchise tax. If this is a tax upon the mere right to be a corporation, graded by the size and the success of the corporation, then it is a tax upon a privilege which can scarcely be said to be property, for, as is asserted by the Supreme Court of the United States as late as last April, the Michigan Mileage Law case, the taking away of this right does not take away *property*, but leaves the company's assets intact. The fact that there are certain privileges given to corporations, such as operating a railroad, which are not given to individuals, adds to the value of many corporate franchises, because it makes them necessities in those particular lines of business.

A great variety of opinion has also emerged from the discussion of Mr. Ford's statement as to the simplicity of determining the value of a franchise such as he proposes to tax. He would take the market value of the stock, plus the market value of the bonded and other indebtedness of the company as being equivalent to the total value of all the assets tangible and intangible. Under the present law, it being the duty of the assessors to appraise the tangible assets, we have, according to Mr. Ford, only to take the value of those tangible assets as found by them and deduct it from the total market price of the securities of the company and we have the value of that intangible asset, which is to be called a "local" or "special franchise."

Many of the comments upon this method of arriving at the valuation have held it up to ridicule, and we think very justly so if it is taken as a rule which can be applied generally; and this, notwithstanding the fact (which seems to

* Communications relating to this department may be addressed to the Editors, Johnston Building, 30 Broad Street, New York.

have been overlooked) that this very rule has been applied in particular instances in Massachusetts and Illinois by the highest courts of those States and in the Supreme Court of the United States. *(Com. vs. Hamilton Mfg. Co., 12 Allen, 312; Aff., 6 Wallace, U. S., 632; Porter vs. Rockford, etc., Co., 76 Ill., 561; Illinois Railroad Tax Cases, 92 U. S., 575).*

This method, happily, is not embodied in the Ford bill, and the local authorities (or according to the amended bill, the State Assessors), will, under the decisions and subject to the review of the courts, be compelled to formulate a general rule or else a rule for each particular case. The latter method, we venture to predict, relying upon the general trend of the decisions of the Court of Appeals in tax cases, will be insisted upon by the courts.

If Mr. Ford's rule was applied to some cases, it would necessarily result in the greatest injustice. For example, a large proportion of a company's debt, represented, perhaps, by an issue or part of an issue of bonds or other securities, may arise out of bad management or peculation. This is especially possible in the small companies; but these bonds for which the company has nothing to show in tangible assets would increase the estimated value of the franchise, according to Mr. Ford's method, by an amount equal to their full value. *Very many things besides the franchise may make up the difference between the Stock Exchange value of the total capital stock and the issue of bonds on the one hand and the estimated value of the tangible assets on the other hand.*

Some effort has been made in the amendments to the bill to partially avoid double taxation, but they are not in the form that they undoubtedly would be had this matter been taken up with that deliberation which legislation of this character demands, rather than with that snap and push and energy which is more commendable on the battlefield and, even, in the strictly executive functions exercised by a Governor, than it is in the enactment of legislation—especially, legislation dealing with so supreme and complicated a subject as taxation.

Manifestly, the bill has been improved by the amendments, but there must be very grave doubts, in the minds of every one, as to whether it would not have been better to have had a measure like this discussed more fully, and there seems to be a reasonable certainty that the other amendments may have to be passed, even if the law is not radically altered at the next session of the Legislature.

If a company in one town or village pays a fixed sum annually to local authorities for rights in public streets, and another company pays for similar rights by paving the street and agreeing to keep it in repair, why should one company have a deduction made from its "special franchise" tax and the other company have no deduction? This is what the amendment to the Ford bill does.

The chief problem involved is not the question as to whether these intangible assets shall be taxed, but how the tax asssessors are to arrive at the value of the intangible assets for the purpose of taxation. This matter has vexed the Legislatures and courts of all the States, and much can be learned from their experience; and no one should attempt to frame a bill or advise the passage of one dealing with the subject until after an exhaustive study by skilled counsellors of that experience as it appears in the statutes and in the decisions of the courts of the various States.

Among the many ways other than that adopted by the Ford bill by which a franchise tax can be measured are the following: By dividends, by the gross receipts, by the net earnings, by the amount of the capital stock at its market value, by the market value of the shares and other securities less the value of the real and personal property (which is Mr. Ford's method, but not necessarily the method to be adopted by the State Assessors); and, finally, by a careful consideration of each case on its merits, giving weight to many, if not all, of the various indicia of value, instead of founding an estimate upon only one of them.

H.

CHARTERS, ORDINANCES, FRANCHISES, ETC.

ILLINOIS.—Mandamus to Street Railroad—Use of Streets—Control of Fares—Estoppel—Contracts—Ultra Vires—Procedure.

1. Where a corporation accepts a public franchise, imposing certain duties to the public in return for rights conferred, the performance of such duties may be compelled by mandamus.

2. The State's power to attach conditions beneficial to the public to the charter of a quasi public corporation may be exercised by a municipality, as within its delegated power to permit the use of streets and public places by the corporation.

3. Const. art. 11, sec. 12, authorizes the general assembly to enact laws to prevent extortion and unjust discrimination by street railways in the transportation of passengers. Held, that though the Legislature had enacted no laws to carry out the provisions, it was, notwithstanding, a declaration of the sovereign power over a street railway's duties to the public to demand only reasonable rates, without unjust discrimination.

4. An ordinance of R., authorizing defendant to enter and use its streets for the operation of a street suburban railroad to Chicago, provided that the fare between any point in R. and the city of Chicago should not exceed the fare charged from any point in the town of C., etc., to the same point, or return. Held, that by the acceptance of the ordinance, defendant was estopped to deny that the exaction of a greater sum from R. to Chicago than from C. was an unreasonable and unjust discrimination against the public.

5. The fact that a city ordinance imposing conditions on a quasi public corporation, in consideration of the privileges granted, required the corporation to accept it, does not render it a mere license, or such ordinance a mere private contract.

6. Since the street railway company has no power to use the streets of a city, in the absence of an ordinance permitting it, the granting of such privilege is a sufficient consideration for obligations imposed and assumed by the acceptance of the ordinance.

7. Where a street railway has enjoyed the benefits of an ordinance requiring performance of certain conditions and obligations by it, it cannot escape performance on the ground that the ordinance and duties imposed were ultra vires to both the city and the company.

8. An obligation imposed on a street railway company by a city ordinance, to demand no greater rates between certain points than between certain other points, is a provision for the protection of the public against unjust discrimination; and hence any citizen is entitled to maintain mandamus for its enforcement.

9. In mandamus begun in the Supreme Court, that court may alow an issue of fact to be made after submission of the case and demurrer to the petition, or not, in its discretion.—(People ex rel., Jackson vs. Suburban R. Co., 53 N. E. Rep., 349.)

ILLINOIS.—Appeal—Reversal — Amendment — Eminent Domain—Necessity.

1. Where the judgment in a petition for condemnation is reversed, and the cause remanded, on the ground that the petition should have stated facts showing the necessity for appropriating the lands in question, the Circuit Court properly allowed an amendment to the petition stating such necessity, and admitted evidence of the facts alleged.

2. Under Rev. St., chap. 66, relating to horse and dummy railroads, and the eminent domain act (Id., chap. 47), allowing the condemnation of property when "necessary" for the construction or operation of such roads, the necessity is not an absolute physical necessity, but one created by expediency or reasonable convenience.

3. A street railway approached a public crossing at an elevation where there were six tracks of a steam railway company, with trains passing and repassing every fifteen minutes. The street railway would have to cross these tracks and the center of the yard of the railroad, if it kept its tracks within the highway. Held, that a necessity arose, within Rev. St., chap. 66, in relation to horse and dummy railroads, and the eminent domain act (Id., chap. 47), so as to authorize a condemnation of private property to avoid the obstacles in ascending and descending a hill near such tracks, and the danger of the grade crossing.—(Aurora & G. Ry. Co. vs. Harvey, et al., 53 N. E. Rep., 331.)

MINNESOTA.—Taxation—Equality—Irregularities—Statutes—Partial Invalidity—Corporations.

1. Gen. St., 1894, sec. 1530, was designed to constitute the ex-

clusive method of listing and assessing for taxation the franchises and other intangible property of corporations and associations falling within its purview. The method there provided for reaching such intangible property for taxation is by listing and assessing the entire capital stock at its market or actual value, less certain specified deductions.

2. The personal property referred to in item 7 is the tangible property specifically listed and assessed, and does not include "franchises." Item 14 of section 1524, Gen. St., 1894, providing for listing "franchises" as a separate and distinct class of personal property, applies only to private persons, or others not falling within the provisions of section 1530. The provision in section 1530 for deducting the total amount of the indebtedness of a corporation or association from the value of its stock is unconstitutional, because resulting in inequality of taxation. But the invalidity of this provision does not render the remainder of the section invalid.

3. Certain irregularities of the county board and county auditor in increasing the assessed value of items 18 and 27 of personal property, and in extending it on the assessment rolls. Held, not to have prejudiced the defendants; it not appearing that, as thus increased, either item was overvalued. Gen St., 1894, sec. 1669, providing for the taxation of railroad companies by requiring them to pay a percentage on their gross earnings, does not apply to street railroads.

4. Held, that upon the facts the Duluth Street Railway Company is not a "railroad company," within the meaning of section 1669, Gen. St., 1894.—(State vs. Duluth G. & W. Co., et al., 78 N. W. Rep., 1032.)

MISSOURI.—Municipal Corporations—Jurisdiction of the Circuit Court—Use of Tracks—Compensation.

1. Under Const. art. 6, sec. 22, giving the Circuit Court Appellate jurisdiction from inferior tribunals as may be provided by law, and under the charter of St. Louis, the city may, by ordinance of its assembly, confer on the Circuit Court jurisdiction to review the award of commissioners appointed to fix the just compensation to be paid by one street railway company for the use of another's tracks.

2. Under the charter of St. Louis, which allows one street railway to use another's tracks on payment of a just compensation, and Ordinance No. 12,562, sec. 3, requiring the commissioners appointed to ascertain the just compensation to hear proofs as to such damages as they may deem just, where the company whose tracks are used did not have an exclusive franchise to use the street, but had agreed to permit any other road to use its tracks, it is not entitled, as part of the compensation, to loss of profits from competition of the other company.

3. Where a street railway company has abandoned its cable line, filled up its conduit, and is operating an electric line, the value of the road at the time another company seeks to use its tracks, and not the original cost of constructing the cable line, is the proper basis of the annual interest to be paid by the second company as part of the just compensation for use of the former's tracks.

4. Where one street railway company uses part of another's tracks, it should not be required, as part of the just compensation therefore, to pay any proportion of the latter company's special franchise tax, payment of half the annual property tax on the tracks used being sufficient.

5. Where one street railway company using another's tracks is required to make and maintain connections and pay switchmen, it is properly allowed to select and employ such switchmen.—(Grand Ave. Ry. Co. vs. Citizens Ry. Co., 50 S. W. Rep., 305.)

MISSOURI.—Municipal Corporations—Jurisdiction of Circuit Court—Use of Tracks.

1. Const. art. 12, sec. 20, prohibits the general assembly from granting the right to construct and operate a street railroad within a municipality without first acquiring the consent of the local authorities. The freeholders' charter of St. Louis, which, under Const. art. 9, sec. 25, is the organic law of the city, by article 10 gives the municipal assembly power by ordinance to determine all questions with regard to street railways, section 6 giving any such company the right to use another company's tracks on payment of just compensation, under such regulations as may be prescribed by ordinance. Ordinance No. 12,652 provides that such compensation shall be determined by commissioners, to be appointed in a manner prescribed. Const. art. 6, sec. 22, gives the Circuit Court appellate jurisdiction from inferior tribunals, as may be provided by law. Held, that the municipal assembly might by ordinance confer on the Circuit Court jurisdiction to review the award of the commissioners.

2. Under an ordinance regulating the use by one street railway company of another's tracks, which provides that the former shall construct and keep the connections with the latter's tracks, the former has the right to select and control the persons employed to handle the switches whose wages it is required to pay.—(Grand Ave. Ry. Co. vs. Lindell Ry. Co., 50 S. W. Rep., 302.)

MONTANA.—Duty to Operate—Ordinance—Mandamus—An ordinance granting a street railway company the right to construct and operate lines in certain streets, and providing that, if the company shall not construct and operate a certain portion of the line within a certain time, the right shall be forfeited, as to the parts where the failure occurs, does not impose on the company the duty to continue the operation of any portion of the line; and mandamus cannot issue to compel it to do so.—(State ex rel., Knight, et al., vs. Helena Power & Light Co., 56 Pac. Rep., 685.)

NEW JERSEY.—Constitutional Law—Judicial and Legislative Functions—Equity Jurisdiction—Injunction—Forfeiture of Franchise.

1. Though a township ordinance granting powers and franchises to a street railway corporation provides that the township may adjudge a breach of duties and obligations and declare a forfeiture, an ordinance passed pursuant thereto, declaring a forfeiture and decreeing a sale of the corporate property, is judicial in its character, and equity has the same power to intervene and modify the proceeding as it would have to interfere in a proceeding in a court of law.

2. When a judicial act is in any particular contrary to the principles of equity, the fact that there may be a remedy at law on other grounds is not generally a sufficient reason to prevent equity from interposing its appropriate remedy on grounds not available at law.

3. Where a street railway corporation has expended large sums of money and exercised due diligence in building and operating its road, so as to comply with an ordinance of permission, but unforseen circumstances have caused a delay, which has occasioned no pecuniary injury to the township or its inhabitants, equity will interfere to restrain the adoption of an ordinance by the township declaring a forfeiture of the franchise of the corporation because it did not comply with the statute of permission, which provided that cars should be running at a certain headway, on a continuous line of double track, within a specified time.—(North Jersey St. Ry. Co. vs. Inhabitants of Township of South Orange, 43 Atl. Rep., 53.)

NEW YORK.—Carriers—Fares—Where a person boards an open street car, and then, because of a sudden change in the weather, leaves such car, and takes passage in a closed one, attached to the other, he becomes a new passenger, and liable for another fare.—(Lasker vs. Third Ave. R. Co., 57 N. Y. Suppl., 395.)

NEW YORK.—New York City Court—Removal of Causes.

1. Under Greater New York Charter, sec. 1366, providing that a defendant may apply to the justice holding court in the district in which the action is brought for its removal to the City Court of New York, an action is not removable on application of one of several defendants.

2. Mandamus—Remedy by Appeal—Mandamus will not lie on refusal of district court to remove case to City Court of New York, the remedy being by appeal.—(People ex rel., Metropolitan St. Ry. Co. vs. Roesch, 57 N. Y. Suppl., 295.)

NEW YORK.—Municipal Corporations—Construction—The power conferred upon the city of Buffalo (Laws 1870, chap. 519, title 3, sec. 19) to permit railroads to cross streets is not independent of, and free from, the limitations imposed by the general railroad act (Laws 1850, chap. 140, sec. 28, subd. 5). The railroad act confers the right to occupy the highway, upon a consent being given, and the charter prescribed by what vote the permission of the city authorities shall be expressed; and the right, when thus acquired by a railroad company, can be exercised only in the proper way, and with a due regard to the public convenience.—(Delaware, L. & W. R. Co. vs. City of Buffalo, et al., 53 N. E. Rep., 533.)

NEW YORK.—Corporations—Action by Stockholder—Pleading—Sufficiency—Relief in Equity.

1. A complaint, in an action by a stockholder to set aside a lease of corporate property, alleging that the scheme of leasing was unlawful, and that the intent of the stockholders approving the lease was to defraud the others, and setting forth the method of accomplishing the fraud, without a motion by defendants to make it more explicit, is sufficient for the introduction of every fact showing an intention of the stockholders approving the lease to defraud the others.

2. Where a stockholder brings an action to set aside a lease executed by the corporation, it is not for his benefit alone, but for the corporation; and his complaint must allege that the corporation was applied to, and refused, to prosecute the suit.

3. A complaint, in an action by a stockholder to set aside a lease by the corporation, alleging that complainant demanded his share of the proceeds of operating the property under the lease;

that he notified the directors that the lease injured the stockholders, and demanded a distribution of the profits arising from the operation, without regard to the lease; and that such distribution involved such action of the directors as would annul the lease, is sufficient to authorize the stockholder to maintain the suit, the allegations not being equivalent to an averment that the corporation was applied to, and refused, to sue to set aside the lease.

4. Where directors of a corporation execute a fraudulent contract with a third party on the express approval of a required number of stockholders, and the scheme will result in serious injury to them or to the corporation, equity will set aside the fraudulent transaction, and compel the delinquent parties to account.—(Flynn vs. Brooklyn City R. Co. et al., 53 N. E. Rep., 520.)

NEW YORK.—Appeal—Review—Findings—Eminent Domain—Elevated Railroads—Damages to Abutting Property—Evidence.

1. If findings prove irreconcilable, it is the duty of the Appellate Court to accept those most favorable to appellant, as he is entitled to rely on them in aid of his exceptions.

2. When fee value of property abutting on a street through which an elevated railroad is operated has steadily declined since the construction of the road, while property on the abutting streets in the immediate neighborhood, with no railroad in front of it, has steadily advanced, and the rents from the property during the period when the road was being built decreased $5000, and, though there was some increase after the road was completed, they have never come to within $4000 of what they were before, while rents on the side streets have rapidly increased, in the absence of any explanation, the inference is that the presence and operation of the road has kept the value of the abutting property down.

3. On appeal from a judgment of the general term of the Court of Common Pleas of the city and county of New York, the unanimous affirmance by that court does not have the effect of a unanimous affirmance by an Appellate Division; and hence a finding made without evidence to sustain it is a ruling on a question of law, which, when duly excepted to, it is the duty of the Court of Appeals to review.

4. Evidence that a station has been located two blocks away from hotel property that it is claimed has been damaged by the construction and operation of an elevated railroad, in the absence of evidence that people in large or small numbers used the station, or that any more people passed by or patronized the property in question after the construction of the road and the building of the station than before, or that the station was of any special benefit to the property, will not justify a finding that the property has been materially benefited by the construction and operation of the road.—(Israel vs. Metropolitan El. Ry. Co. et al., 53 N. E. Rep., 517.)

OREGON.—Receivers—Claims—An order appointing a receiver for a street railroad in forclosure proceedings, and directing him to pay "all current expenses incident to the administration of his trust, and to the condition and operation of said business, from time to time, as the same arises and accrues," does not require the receiver to pay any debt not entitled to preference over the mortgage creditors, or such as accrued prior to his appointment.—(McCornack vs. Salem Consol. St. Ry. Co. et al., 56 Pac. Rep., 1022.)

PATENT DECISIONS.

1.—Patents—Invention — Electric Railways — After dynamic-electric machines and electric motors were invented, sufficiently powerful and economical to operate a stret railway, there was no invention in combining them with a track and cars by a plan or system previously well known, and which had been unsuccessful solely because the electric machines then in use were defective.

2.—Same—The only combination shown in the specifications of a patent for an electric railway was one in which the electricity is carried by one insulated rail and the wheels on it to the motor, and back by the wheels and the other rail. There was a suggestion that independent conductors might be used, but no suggestion as to how contact therewith was to be maintained by the moving car; and at that time there was no practical device for maintaining contact with an overhead wire. Held, that the patent could not be pieced out, by reference to the art, so as to include in the combination an overhead wire and contact device.

3.—Same—The Green patents, Nos. 465,407 and 465,432, for an electric railway and means of operating the same, if valid at all in view of the previous state of the art, are confined to a combination in which the electricity is carried to the motor by one insulated rail and the car wheels, and back through the other wheels and rail or the ground, and is not infringed by the overhead wire and trolley-contact system.—(Kelly et al. vs. Springfield Ry. Co. et al., 92 Federal Rep., 614.)

LIABILITY FOR NEGLIGENCE.

ILLINOIS.—Cable Cars—Carriers—Passengers—Standing on Platform—It is not contributory negligence, per se, for a passenger on a cable car to ride on the rear platform, where others do it without objection, and there is no rule against so doing.—(North Chicago St. R. Co., 53 N. E. Rep., 568.)

INDIANA.—Master and Servant—Injuries to Servant—Action—Complaint—Special Verdict—Assumption of Risk—Negligence—Proximate Cause—Ordinance.

1. Under a complaint by an employee of a street railway company, merely alleging that the injuries resulted from the negligence of the company in running its cars, the employee cannot prove that they resulted from the failure of the employer to provide a safe place to work, and safe machinery, or that the injuries were willful.

2. One employed by a street railway company to turn switches at the intersection of several lines was familiar with the surroundings, and there was room for him to stand safely between the tracks. Having turned a switch, a car passed him, immediately followed by another, drawn by horses, which were prancing about, and to avoid injury therefrom the employee stepped back toward the other track, and was struck by a car thereon, moving in an opposite direction at 8 or 10 miles an hour, contrary to an ordinance limiting the speed to 6 miles. Held, that the appearance of the horses was the proximate cause of the accident, and not the speed of the car which struck the employee.

3. One employed by a street railway company to turn switches at the intersection of several lines assumed the risk of accidents caused by the switching of the cars.

4. A special verdict that the place of the accident, which was a curve on a street railway track, was rendered unsafe by the sway of the car, was not a finding that the improper speed of the car caused it to sway.

5. Where it is sought to make an ordinance, entitled one to authorize the operation of certain passenger railways on the city's streets, applicable to a company operating nearly twenty years after its passage, it should be shown that such company was existing when the ordinance was passed, and was one of the railways therein designated.—(Thompson vs. Citizens' St. R. Co., 53 N. E. Rep., 462.)

KENTUCKY.—Carriers—Negligence as to Passenger on Street Car—When Relation Ceases—Speed of Car as Negligence—Omission of signals.

1. Either the rapid speed of a street car at a public crossing in a populous city in the evening, or the failure to give a signal of the approach of the car to the crossing, is negligence, as to a passenger attempting to cross the track after alighting from another car of the same company moving in the opposite direction on a parallel track.

2. A passenger upon alighting from a street car does not cease to be a passenger, but is entitled to protection against the negligent management of cars by the same company on a parallel track.

3. Defendant having elicited from plaintiff, on his cross-examination as a witness, the fact that he had served a term in the workhouse, it was not error to permit an explanation by the witness of the offense for which he was convicted.—(South Covington & C. St. Ry. Co. vs. Beatty, 50 S. W. Rep., 239.)

MICHIGAN.—Trial—Province of Jury—Contributory Negligence—Witnesses—Interest.

1. Where the evidence is open to a construction that renders it conflicting, it is not error to refuse to withdraw the case from the jury.

2. It is not negligence for a passenger to ride on the running board of a street car, where the car is full, and he cannot get inside.

3. Where a witness testified, on cross-examination, that he went to defendant to see about a settlement for plaintiff's injuries, it is not error to sustain an objection to a question whether witness had told defendant the amount for which he would settle; his interest already appearing from his testimony.—Pomaski vs. Grant, 78 N. W. Rep., 892.)

MINNESOTA.—Costs—Rights of Prevailing Party—Witness Fees.

1. Actions were brought by different plaintiffs, husband and wife, against the same defendant, to recover for injuries received in the same accident. By consent of all parties, the cases were tried together, separate verdicts being rendered. Plaintiff's wife had a verdict on which her costs and disbursements were taxed and allowed, judgment entered, and paid. In the other action the verdict was in defendant's favor. Held, that under the provisions of Gen. St., 1894, sec. 5498, the defendant, prevailing party in the action brought by the husband, was entitled to recover $10 statutory costs, therein prescribed.

2. Held, further, that under section 5500, Gen. St., 1894, defendant, prevailing party in the action brought by the husband, was also entitled to recover disbursements paid or incurred as fees for witnesses who were subpœnaed and attended in that action, although it was admitted that the witnesses were as necessary and material in one case as in the other, and would have been produced and sworn in both, had there been separate trials.

3. It is not error to allow fees for travel and attendance of witnesses, who are not sworn at the trial, where the attendance of such witnesses is regularly proved. And fees of witnesses actually in attendance, though not called to testify, are properly taxed, where, if a certain state of facts had been shown by the other party, his opponent would have been compelled to call such witnesses.—(Schuler vs. Minneapolis St. Ry. Co., 78 N. W. Rep., 881.)

MISSOURI.—Injuries to Passenger—Negligence—Pleading—Evidence—Province of Jury.

1. Rev. St., 1889, sec. 2074, requires that in construing a pleading to determine its effect its allegations shall be liberally construed with a view to substantial justice. A petition alleged that a passenger on a street car requested the conductor to let her off at a certain street; that, on reaching there, it appeared that the car was not going to stop, and the passenger again indicated to the conductor her wish to get off there; that immediately, as if in response to her request, the car slowed down, until its motion was scarcely perceptible, when she attempted to alight; and that while doing so the car started suddenly, and she was thrown down. Held, after verdict, that it did not charge that the passenger specifically requested to be let off at an unusual place, but it implied that the car was stopped at her request, and that the conductor saw, or should have seen, her alighting; so that it was unnecessary to allege that the car started before she had time to alight.

2. Several blocks before reaching a crossing, a passenger on a street car told the conductor to let her off there, and, seeing that the car was about to pass that point, she again signaled him to let her off, and he nodded to her. Immediately the car slowed down until the motion was scarcely perceptible, when she attempted to alight, taking hold of the railing, and, when one foot was on the ground, the car suddenly started, throwing her. The company claimed that the car slowed up where it did, as was usual, to enable the motorman to see if there were any cars on an intersecting line on the next street, but the testimony did not show that the passenger knew this, or knew that it was unlawful to stop in the middle of a block to discharge passengers. She knew it was customary for the conductor to ring the bell to stop, but testified that she did not know whether he rang it this time or not, and that she did not see him after she signaled. Held, that the case was properly left to the jury to determine whether the passenger was justified in alighting.

3. The passenger and several witnesses testified that they did not notice whether the conductor rang the bell, but all the witnesses except one, who was on the sidewalk, were on the rear car. One witness testified that the conductor placed his hand on the bell rope. Held, that the evidence raised the question whether the car was stopped to let the passenger off.

4. The last witness also testified that, after the passenger had fallen, the conductor asked witness if he had seen that. Held, that the evidence raised the question whether the conductor saw the passenger attempting to alight.

5. While a street car was crossing a street, a passenger signaled the conductor to stop, and the car slowed up, coming nearly to a standstill, between such street and the next one. The passenger attempted to alight, and was thrown by the sudden starting of the car. The company claimed that the car was slackened, as was customary, to enable the motorman to ascertain whether there were any cars on an intersecting line on the next street, and that the conductor understood the passenger's signal as one to stop at such street. Held, that a very high degree of care was required of the conductor in regard to the signal.—(Cobb vs. Lindell Ry. Co., 50 S. W. Rep., 310.)

NEW JERSEY.—Contributory Negligence—A boy, nine and one-half years of age, while playing in the street, ran in front of a trolley car which he saw approaching, and was struck by the further corner of the fender. Held, that there was no element of danger which he did not perceive or which a boy of his years was not capable of fully appreciating, and that, therefore, he took the risk of failing in the attempt which he designedly made.—(Brady vs. Consolidated Traction Co., 42 Atl. Rep., 1054.)

NEW JERSEY.—Negligence—Obstruction in Street—New Trial—Newly Discovered Evidence.

1. While a street car company has the right to place a pile of car track rails upon the street, temporarily, for its use in reconstructing or repairing its car track, yet it is bound to the duty to exercise reasonable care to guard the public using the street against the danger arising from the rails so placed upon the street, and in the night-time to place a guard or signal of warning to persons using the street; and this duty exists whether the pile of rails be placed in the gutter of the street or in some other portion thereof.

2. Where the plaintiff, in the night-time, had come from a house on the street, and was endeavoring to cross over the curb and street to board a street car, and in doing so stumbled and fell upon a pile of street car rails placed in the gutter or alongside the street over which he was crossing in order to take the car, the pile of rails extending a few inches above the curb, there being no signal of danger or guard placed there to warn the plaintiff of the existence of the pile of rails at that place, and the street lamps or lights being at some distance away up and down and across the street, and, under the evidence, it being a matter of fair controversy whether the rails could be seen by the plaintiff in the exercise of ordinary care in passing over the gutter or side of the street, a case is presented which calls, as matter of fact, for a determination by the jury whether the defendant company, which placed the pile of rails in the gutter, had exercised reasonable care to protect the plaintiff from the injury arising to him by reason of his fall, and also whether the plaintiff himself had exercised reasonable or ordinary care in passing over the street to reach the car.

3. Newly discovered evidence in behalf of the defendant, tending to show the existence of lights in the vicinity, as bearing upon the question of the negligence of the defendant and the contributory negligence of the plaintiff, in order to be considered on a rule to show cause why the verdict should not be set aside, must be such as is not merely cumulative, and such as could not have been produced at the trial by the exercise of ordinary diligence on the part of the defendant.—(Thomas vs. Consolidated Traction Co., 42 Atl. Rep., 1061.)

NEW JERSEY.—Collision With Vehicle—The driver of a vehicle upon a road used by the public at large, which crosses the track of an electric railway, must exercise reasonable care to avoid collision, and the same duty rests upon the motorman of a trolley car in approaching the crossing of such a road, whether the crossing is in the country or in a town; and, in case of accident, the question whether either or both of said parties failed in such duty is one to be determined by the jury, when the proofs on the subject of negligence leave that question in doubt. Neither party at such a crossing has a paramount right of way.—(Atlantic Coast Elec. R. Co. vs. Rennard & Wilson, 42 Atl. Rep., 1041.)

NEW YORK.—Personal Injuries—Complaint—Specificness.

1. A complaint in a personal injury case, alleging that the occurrence inflicted severe injuries on plaintiff from which he has not recovered and will not recover, and that by reason of the injuries he has been unable to follow his usual occupation or do any work, and that he has suffered great pain, is sufficiently specific to warrant evidence as to any effects of the injuries received, in the absence of a motion to make the complaint more definite or for a bill of particulars.

2. Appeal—Matters Not in Record—Where the record does not contain a bill of particulars, the Appellate Court cannot consider its alleged contents.

3. Trial—Examination of Witnesses by the Judge—The action of the trial judge, in practically conducting plaintiff's case by examining plaintiff and his witnesses while on the stand, as to points not yet touched on by the counsel, by asking them questions which would have been incompetent if asked by plaintiff's counsel, and which were leading and suggestive, warrants a reversal.—(Bolte vs. Third Ave. R. Co., 56 N. Y. Suppl., 1038.)

NEW YORK.—Injury to Pedestrian—Evidence—A verdict against a street railway company for injury to a child four years old, struck by a horse car, is properly set aside as against evidence, the proof being that the car was 73 ft. away when the child and her older sister were at the first rail of the track, and it being apparent that the jury failed to consider the gross improbability of the car proceeding that distance while they were walking only part of the distance across the track.—(Gordon vs. Second Ave. R. Co., 57 N. Y. Suppl., 298.)

NEW YORK.—Injury on Crossing—Question for Jury—A building at the intersection of a private driveway leading from a public resort, and a street railway, obstructed the view of an approaching car. The building was only a few feet from the track. Plaintiff, who was proceeding along the driveway at night, without listening for a car, went upon the crossing and was struck. The car was running at a high rate, and did not slacken its speed. No gong was sounded nor other signal given. At that time of the evening many people were accustomed to leave such resort by the driveway. Held, sufficient to justify a submission of the case to the jury.—(Duncan vs. Union Ry. Co. of N. Y. City, 57 N. Y. Suppl., 326.)

NEW YORK.—Accident to Passenger—Evidence—Testimony of plaintiff that, after defendant's car had stopped, she was alight-

ing from the rear platform, with her right hand on the rail of the dashboard, and one foot in the air, ready to step off, when the car started, throwing her "forward," is not necessarily untrue.—(Bosting vs. Brooklyn Heights R. Co., 57 N. Y. Suppl., 119.)

NEW YORK.—Collision—Contributory Negligence—One who, seeing an electric car only part of a block away, coming very fast on a down grade, starts to cross the track diagonally for a cross street, passing close to a pillar of an elevated railroad, against which he is driven by the car, is prevented by contributory negligence from recovering therefor.—(May vs. Metropolitan St. Ry. Co., 57 N. Y. Suppl., 277.)

NEW YORK.—Collision—Contributory Negligence—Contributory negligence is a question for the jury, where the plaintiff, driving along a street, and coming first to the track on the avenue on which the up-bound street cars run, had to turn the heads of his horses slightly to avoid a collision with such a car, and then, getting on such track, saw a car half a block away coming down on the other track, and, the crossing being clear, proceeded at a fast walk, and was struck by such car after the horses and front wheels of his wagon had got over the second track.—(Reilly vs. Metropolitan St. Ry. Co., 57 N. Y. Suppl., 278.)

NEW YORK.—Collision—Contributory Negligence—One who, seeing a cable car coming, half a block away, very fast—at the full speed of the cable—gets into his wagon, covered at the sides, and, without looking further, starts to cross the track, is prevented by contributory negligence from recovering for injuries received.—(Lang vs. Metropolitan St. Ry. Co., 57 N. Y. Suppl., 249.)

NEW YORK.—Negligence—Sufficiency of Evidence.

1. In an action for negligence, where plaintiff's evidence is not corroborated, and a defense is made out by disinterested witnesses, a verdict for plaintiff is against the weight of the evidence.

2. Damages—Personal Injuries—Pleading—Evidence—In an action for personal injuries, evidence of bodily ills, not complained of in the pleadings, is inadmissible.—(Hess vs. Metropolitan St. Ry. Co., 57 N. Y. Suppl., 222.)

OHIO.—Wrongful Death—Recovery Limited to Pecuniary Loss for Mental Suffering—Competency of Evidence—Injury to Railway Employee.

1. While, in the trial of a case for causing death by wrongful act, neglect, or default, under sections 6134, 6135, Rev. St., the recovery is limited to the pecuniary injury resulting from such death to the beneficiaries, and nothing can be allowed on account of bereavement, mental suffering, or punitive damages, yet any evidence which tends to show the amount of such pecuniary injuries sustained by such beneficiaries, or which tends to show that such beneficiaries received financial aid from the deceased during his lifetime, and that they would likely have continued to receive such aid had he lived, is competent; and for the purpose of showing that such beneficiaries needed, and would likely have received, such aid from the deceased, the circumstances, age, health and means of support of the beneficiary, if a parent or next of kin of the deceased, as well as the age, health, disposition and thrift of the deceased, may be shown.

2. Rules adopted by a street railway company for the government of its employees in operating such railway are competent evidence, when relevant, in the trial of a cause for damages for personal injury caused by the negligence of the servants of such company.—(Cincinnati St. Ry. Co. vs. Altemeier, 53 N. E. Rep., 300.)

Legal Book Notices

NEGLIGENCE CASES*

In the December number of the Journal we had occasion to review the excellent work of Mr. Hamilton, entitled "New York Negligence Cases, Classified." It gives us pleasure to note the prompt publication of the supplement to that work, which contains all the cases "classified according to the facts," for the year 1898. The supplement follows the plan of the original work, with this important and useful addition, that in each case the disposition of the case in the first instance (including the amount of the verdict, if for the plaintiff) and the decision on appeal has been added to the brief statement of facts.

Mr. Hamilton's preface contains the interesting information that of the cases reported, with opinions, in the last twelve volumes of the Appellate Reports of New York, over 18 per cent were negligence cases, and about 13 per cent of those in the last four volumes of the Court of Appeal Reports.

These, with the negligence cases, covering the same period in the Miscellaneous Reports (about 7 per cent of the cases there reported) contain over 350 opinions on Negligence Law.

VALUABLE COLLECTION OF ELECTRICAL CASES†

This important and compendious work in six volumes has just been issued from the press of Matthew Bender. We know of no single work which contains as much of value, at first hand, for use in the legal department of electric and street railway companies as this. It contains full reports of between 2000 and 3000 cases, covering a period of twenty-four years. These reports are annotated by the head notes of, and references to, other cases decided during the same period. At the end of each volume is an admirable index which greatly increases the value of the work and makes it a time saver. Of course, an index or digest covering all the volumes under a single alphabet would still further add to its value. The cases in each volume seem to be arranged as far as is practicable, under different subjects, and perhaps the easiest way to give an idea of the value and extent of the work is to indicate the subjects treated of in the last volume, which covers the years 1895 to 1897.

Some fifteen cases are devoted to the powers of municipal corporations over the use by electric companies of streets and highways; of the right of the municipalities to impose license fees, and generally of the rights of electric companies in the streets, excepting those cases which involve the rights of abutting property owners.

The next eight cases treat of the rights of abutting property owners. Then, two cases are reviewed under each of the following topics: Cutting trees; the rights of the telegraph along a steam railroad; the crossing of electrical and steam railroads, and the inference by different companies in the use of the same street.

The next six topics relate to various phases of the law of negligence, and there are from five to thirty-six cases reviewed under each subject: Injuries caused by electric shock, negligence in the use of electrical appliances, negligence causing injuries to employees, the duties of street railway companies to passengers, and the duties of street railway companies to travelers in the street.

Six cases are reported which deal with the taxation of telegraph and other electric companies and their property. One or two cases are devoted to each of the following subjects: The rights of municipalities to supply electric light, discrimination practiced by telephone companies as common carriers, the relation existing by contract and otherwise between the United States, the Union Pacific Railroad and Western Union Telegraph Company.

Finally, nineteen fully reported cases deal with the negligence of telegraph companies in sending and delivering messages. The valuable note to these cases contains head notes of some fifty-six additional cases upon the same subject.

Perhaps in no department of the law is a work of this sort so useful. Ordinarily, especially in the older States of the Union, the practitioner finds precedents at hand in his own library from the courts of his own State, and can quickly advise the officers of the legal department of the corporation for which he is counsel, either out of his own knowledge or from the bookshelves of his own library; but where he is dealing with the legal rules that have to be applied to so new an element of modern commerce as electricity, very many questions arise in the conduct of a company using it which require the application of old principles to an entirely novel state of facts. Precedents have to be looked for not only in the home State of the corporation, but outside of it. It frequently happens that a question has only been decided in one or two States and has not been passed upon by the local courts at all.

This set of volumes is the best work we know of to supply the obvious need which exists in the library, both of the counsel and of the legal department of the corporation who deal with electrical questions. The arrangement of the volumes in chronological order is especially to be commended in a work of this sort, where the law is growing from year to year. For example, the question as to whether it is negligence for a street car company to run electrical cars without fenders is a question which is necessarily much affected by the date of the accident or decision. In 1895 the Supreme Court of Massachusetts decided that in the year 1893, at which time there was but one electric road in Massachusetts using a fender, the absence of a fender was not negligence. Mullen vs. R. R., 6 Am. Electl. Cas., 492. Subsequent volumes of this series will undoubtedly show an advance upon this decision growing out of the general adoption of this safety appliance.

* Supplement to Hamilton's New York Negligence Cases, classified according to the facts, by T. F. Hamilton. Matthew Bender, Albany, N. Y., 1899.

† American Electrical Cases. A collection of all the important cases (excepting patent cases) in the State and Federal Courts from 1873 to 1897, on subjects relating to the telegraph, the telephone, electric light and power, electric railway and all other practical uses of electricity, with annotations. Edited by William W. Morrill. Matthew Bender. Albany, N. Y., 1897.

Electrical Exhibition at Madison Square Garden

The second annual electrical exhibition was held at Madison Square Garden, New York, from May 8 to June 3, under the auspices of the National Electric Light Association. The show was opened on the evening of May 8, at 8.30, by Senator Chauncey M. Depew, who was assisted by A. M. Young, president of the National Electric Light Association, C. O. Baker, Jr., and Marcus Nathan, of the Electrical Exhibition Company. Telegrams of congratulation were received from President McKinley and from Governor Roosevelt.

The exhibition aroused considerable interest and enthusiasm in matters electrical, not only among the trade, but also among the every-day citizens of Greater New York, and it was well attended each afternoon and evening.

The occasion was taken by a number of electrical and technical societies in the vicinity of New York to hold regular and special meetings at the Garden during the exhibition, and in addition to these the National Electric Light Association met in regular convention in the lecture room of the Garden from May 23 to 25, inclusive.

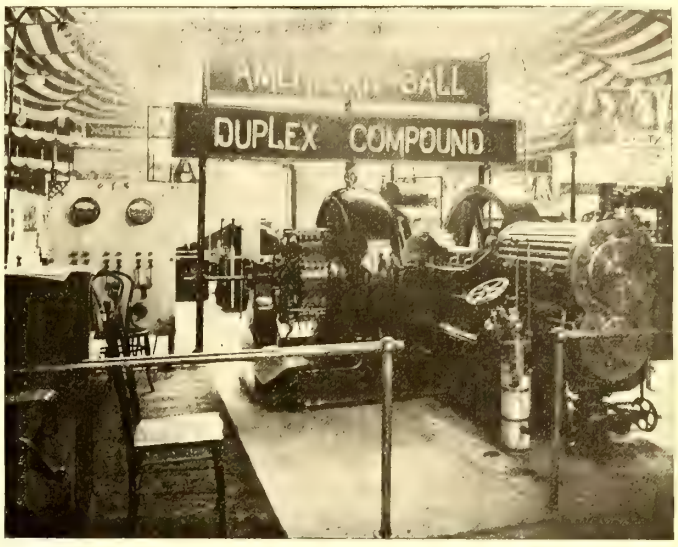
On the evening of May 13 the New York Electrical Society held its 198th meeting, and celebrated the centennial of the discovery of the electric battery by Volta with special exercises. The meeting was held in the concert hall, and was attended by four or five hundred persons, including representatives of several Italian societies.

SOME OF THE EXHIBITS

The main floor of the Garden was filled with well-arranged exhibits of the heavier machinery, apparatus, etc., employed in the generation and distribution of electricity and in allied industries, and in the gallery running around the entire building were placed the lighter exhibits, such as historical and experimental instruments and relics, wireless telegraphy apparatus, etc. Among the exhibits the following may be briefly mentioned:

An attractive display of electrical instruments was made by the Cutter Electrical & Manufacturing Company, of Philadelphia. This company had a three-sided booth, upon the walls of which were hung standard circuit breakers of various capacities, the new Q. & C. rheostat, etc., one of the walls being reserved for what the company calls its freaks, or instruments made to meet extraordinary conditions. A prominent feature of the exhibit was a 1000-amp. single-pole circuit breaker, with laminated contacts.

The Bullock Electric Manufacturing Company, of Cincinnati, Ohio, illustrated in a simple manner the development in the direct application of electric power for the driving of machine tools. The exhibit included four commercial machines, one 25-kw. engine-type generator, a 65-h.p. motor, a belted 10-h.p. motor running at 1050 r.p.m., and a 6-in. x 5-in. Forbes vertical engine direct connected to a 12-kw. dynamo arranged for the Bullock system of control. An artistic feature of this exhibit was a large revolving globe, around the circumference of which appeared the name of the company in incandescent lights.



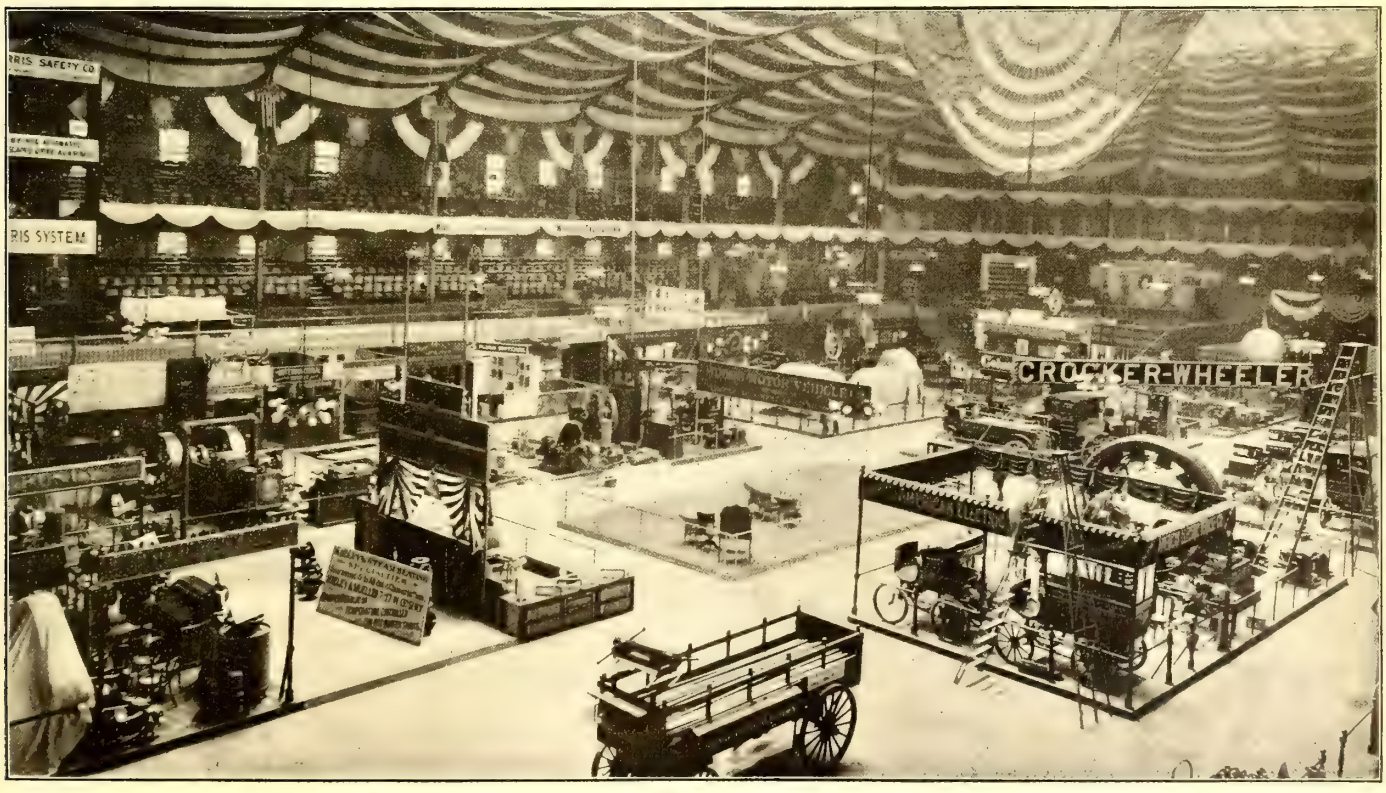


EXHIBIT OF THE AMERICAN ENGINE COMPANY

An exhibit of particular interest to central station managers was made by the Wagner Electric Manufacturing Company, of St. Louis. This comprised a 7½-h.p., 60-cycle, 110-volt, single-phase alternating current generator. The current was taken from the generator through a switchboard, upon which was mounted a number of direct current volt meters and ammeters and alternating current ammeters and volt meters, an indicating watt meter, and other instruments of the Wagner type. Samples of switches were also shown, these being of a new type just brought out by the company.

A time recorder for keeping the time of employees in large factories, street railway repair shops, and other establishments of like nature, was displayed by the Willard & Frick Manufacturing

GENERAL VIEW OF EXHIBITION HALL

Company, of Rochester, N. Y. This instrument does away with the necessity of a separate clerk for timekeeping, each employee making his own record. The system is of such a nature, however, as to prevent fraudulent records.

One of the most interesting features of the show, from a popular point of view, was the collection of automobiles, this being, it is stated, the largest number of electrically propelled vehicles ever brought together at one time. All sorts and conditions of carriages and wagons were shown, including buggies, hansoms, closed and open cabs, delivery wagons, stages, etc. Among the largest exhibits of automobiles were those made by the American Electric Vehicle Company, of Chicago; the Columbia Automobile Company, of Hartford; the Indiana Bicycle Company, of Indianapolis, and the Riker Electric Motor Company.

The American Vitrified Conduit Company showed samples of its multiple duct conduits, containing from two to sixteen ducts. This company in all its conduit work uses dowel pins for alignment in making joints, thus assuring a positive and true joint, and doing away with the necessity of using mandrils in laying the ducts. The company exhibited a subway system laid out in miniature, showing a manhole built of a new type of brick, with a special arch for the top, and covered with the McGregor noiseless manhole frame and cover, made by the McGregor Manufacturing Company, of New York.

The John A. Roebling's Sons Company, of Trenton, N. J., had a very complete display of samples of all its wire products, including bare copper wires, rubber and other insulated wires of all kinds, office and magnet wires, electric light wires, etc. A number of samples were also shown of cables which the Roebling Company has supplied, and which are of historical interest. Among these were sections of the last Commercial Cable. An object of particular interest to street railway men was the special splice of the large three-phase cable for the Metropolitan Street Railway Company, of New York. This cable is made up of three 0000 wires, and will be used for the transmission of high tension current over the company's system. The splice is quite compact, the only visible evidence of its existence being an enlargement about one foot long of the lead casing. Samples of Columbia and flexible rail bonds were also shown.

In one corner of the gallery was shown a device manufactured by the Evans Automatic Illuminating Car Sign Company, of Boston. This is a revolving sign designed to be placed on the front or side of a car, near the transom, and having open letters, through which the light from the interior of the car shows, doing away with the necessity of having extra lights for the sign.

An interesting and instructive exhibit was made by the Union Boiler Tube Cleaner Company, of Pittsburgh, Pa. This company gave practical illustrations of the methods employed in removing scale from the principle types of boilers with the cleaning device which it manufactures. The Union boiler tube cleaner was fully described in the Street Railway Journal for February, and the manufacturers state that it is coming into very extended use. With this apparatus tubes that have become nearly solid with the hardest kind of scale have been thoroughly cleaned and rendered equal to new in less than five minutes. The company showed in operation both the rigid cleaner for straight tubes and the flexible shafting for bent tubes.

The Joseph Dixon Crucible Company, of Jersey City, N. J., had a tasteful booth, in which were shown cases containing samples of graphite products for electricians and electrical industries, including resistance rods from 1 ohm to 1,000,000 ohms, graphite brushes, lubricants for dynamo and motor commutators, etc. The company was represented by John H. Baird, who distributed an acceptable little souvenir made of graphite. Extending the entire length of the booth was a changeable electric sign, which was one of the most attractive at the exhibition.

The H. B. Camp Company, of Aultman, Ohio, made a practical demonstration of the enormous strength of the vitrified clay conduit which it manufactures. It had on exhibition a 15-ft. span composed of sixteen ducts, built entirely without concrete or support of any kind except at the ends. This span had a breaking strain of 32,000 lbs. Various samples of the company's usual and special types of conduit were also shown.

A most tasteful and attractive booth was fitted up by the Safety Insulated Wire & Cable Company of New York. Here all visitors were made perfectly welcome, and something of the company's enormous business was explained to them. A number of samples of particularly interesting cables were shown, among them being sections of cable used in the Philippine Islands, Cuba and Porto Rico by the United States Government for submarine and land lines during the recent war with Spain; also sections of wire used by the telegraph and signal corps. It is a noteworthy fact that all the wire and cables purchased by the United States Government for installing the mine fields in New York, Boston and other harbors during the war were purchased from the New York Safety Insulated Wire & Cable Company, as was also the wire used in the United States Navy. A unique changing electric light sign completed the decorations of the booth.

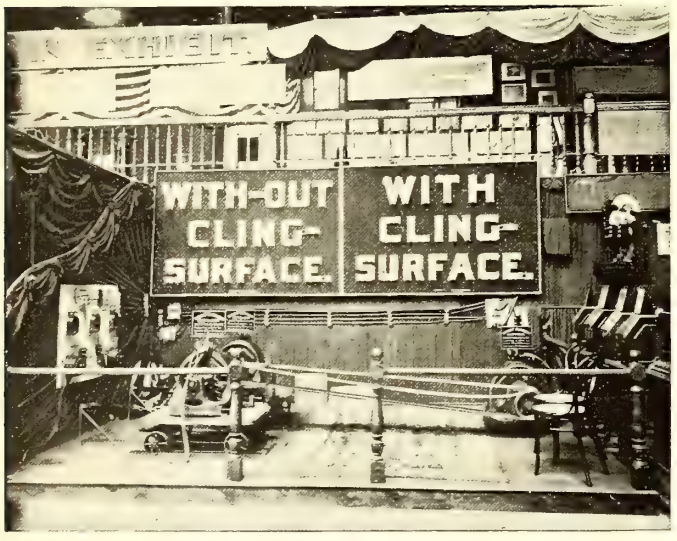

EXHIBIT OF CLING-SURFACE MANUFACTURING COMPANY

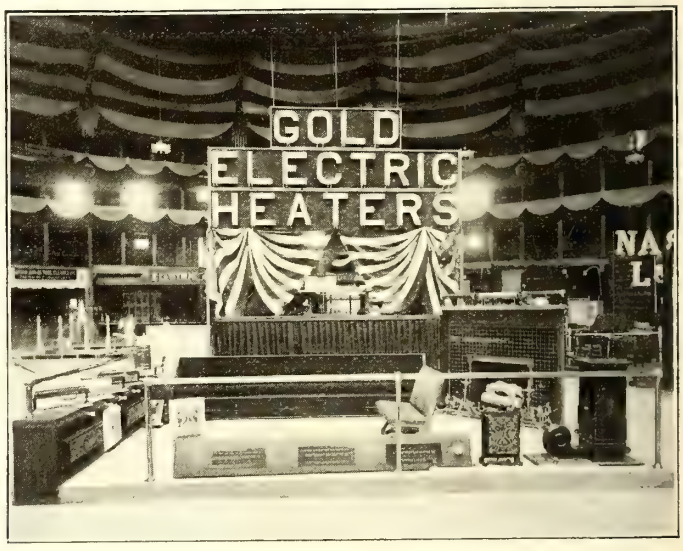

EXHIBIT OF GOLD CAR HEATING COMPANY

The Stirling Company, of Chicago, had on exhibition a full-sized 125-h.p. standard Stirling boiler, showing the details of its construction in the clearest possible manner. A number of strong points are urged in favor of this type of boiler, among them being the advantages in cleaning, as there are no tube caps to remove or replace, the dried steam delivered, and the absence of all injurious strains in the interior due to the alternate heating and cooling. This latter advantage is secured by leaving the lower drum, into which all the tubes enter, without rigid attachment, thus permitting considerable movement of the tubes and drums without strain. In a test of eight hours duration Stirling boilers have been forced 133 1/3 per cent above their rated capacity, and held there through the entire test, without injuring in the slightest degree any of the parts. In actual tests when forcing the boiler 50 per cent above rating the moisture of the steam does not exceed 1½ per cent.

An extremely effective demonstration was made by the Cling-Surface Manufacturing Company, of Buffalo, of the results obtained by the application of cling-surface to belting for the purpose of preventing slipping. The exhibit consisted of a direct current 7½-h.p., 110-volt Westinghouse motor running at 750 r.p.m., and driving, by means of two 4-in. belts on its one pulley, two 3¾-kw., 125-volt Westinghouse multipolar dynamos, each running at 1000 r.p.m. Thus the two dynamos being of the same capacity and deriving their power from the same source enabled a comparison of the performance of the two belts, which were of the same size and made from the same piece of leather. The tension on the belts was obtained by means of heavy spring scales pulling

at the back of the machines, both belts having a tension of 120 lbs. The belt treated with cling-surface was run slack, and, in fact, kept so that both sides touched without in any way affecting the output of the motors. The untreated belt had to be perfectly tight before it would do its work, and any tendency to slacken was immediately noticed by the diminishing of the output. The load on the machine consisted of a bank of lamps forming a sign. Tests were made to show there was no slip on the cling-surface belt, while on the other there was constant slippage. Albert B. Young, manager of the company, had charge of the exhibit.

A very complete line of electric heaters was shown by the Gold Street Car Heating Company, of New York and Chicago. These were the usual forms of the Gold heating appliances having a zigzag rod or support for the resistance coil. The application of the heaters to street cars was shown by a longitudinal car seat fitted with the latest design of the Gold three-degree panel type. This device is divided into three even sections, all of which are controlled by a three-point regulating switch, so that one-third, two-thirds or the full capacity of every heater may be had at any time, according to the outside temperature. The very even methods of graduating insures uniform and comfortable distribution of heat at all times. A Hale & Kilburn walk-over seat was also shown fitted with the Gold standard heater, the construction and connections of which are very simple. Over twenty other designs of electric heaters, using the Gold resistance coil and support, were shown, all suited to different purposes, some of them being designed for steamships, and others for house warming. A very popular feature of this display was the electric fireplace placed at one corner of the booth. This was very attractively arranged, and excited a great deal of interest among visitors. It is well adapted to the heating of country houses, clubs, city residences, etc., wherever electric current is available.

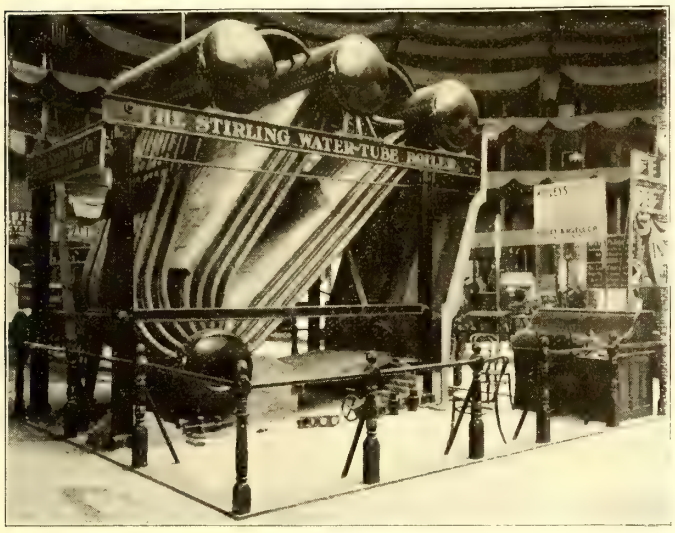

EXHIBIT OF STERLING COMPANY

The H. W. Johns Manufacturing Company of New York presented a novelty in the shape of a non-arcing inclosed fuse. This device is sold under the name of "Noark," and, it is claimed, entirely eliminates injury to electrical apparatus due to overloads or short circuits, at the same time making fires, often resulting from the arc caused by the blowing of the old types of fuses, entirely impossible. The invention consists of a strong inclosing casing filled with a special compound, which quickly and effectually interrupts any excess of current above the fuse's rated capacity. An important feature of the device is the indicator which tells the condition of the fuse at all times, so that there will never be any question as to whether the fuse has blown or not.

The Columbia Incandescent Lamp Company, St. Louis, exhibited a case showing lamp bulbs and filaments in different stages of manufacture. It also had an attractive sign fitted with Columbia lamps. The clear white light given from these lamps indicates the absence of gases in the interior to a remarkable degree. In connection with this exhibit the Bosert Electric Construction Company, of Utica, N. Y., showed samples of its terminal and switch boxes, porcelain cut-outs, porcelain lining and white enamel lining.

The D. & W. Fuse Company, Providence, R. I., had a number of its closed fuses for use with from 50 to 20,000 volts, also samples of its cut-out boxes for underground and overhead construction. This company is bringing out a new quick-make and quick-break switch, which was also shown.

An unusually complete exhibit of electric arc lamps was made by the Adams-Bagnall Electric Company, of Cleveland. Although the company had but a small booth, yet it utilized the space so well that a sample of about a dozen different types of lamps was shown. These included series inclosed, direct current arc lamps for 110 and 220 volts, series open arcs, alternating inclosed arcs, standard potential direct current inclosed arcs for 110 volts, and many others.

A new time recorder for use in factories and other large plants, street railway repair shops, etc., was shown by the Dey Patents Company, of Syracuse, N. Y.

The American Engine Company, Bound Brook, N. J., had in operation a 75-h.p. American Ball engine, directly connected to a 50-kw. generator. This engine attracted unusual attention on account of its smooth and easy running qualities, there being hardly any vibration perceptible even when standing very near the cylinder head. This is a new type of engine that the company is just bringing out, and for which unusual economy under small and varying loads is claimed. Its cylinders are 9½ ins. and 15 ins. x 11 ins. stroke. When running at 290 r.p.m. with 90 lbs. of steam, 25 lbs. of water per i.h.p. per hour are used. The engine is non-condensing.

A novelty in the way of a tower wagon was presented by the Columbia Automobile Company, of New York city. This wagon is operated by storage batteries, and was built for the Consolidated Traction Company, of Pittsburgh. The batteries are of sufficient capacity to carry the wagon 25 or 30 miles without recharging.

EXHIBIT OF BALL & WOOD COMPANY

The Ball & Wood Company of New York exhibited a new 300-h.p. engine with Corliss type valves and self-oiling device. The engine was run non-condensing at 250 r.p.m., with cylinders 16 ins. and 26 ins. x 16 ins. This engine, although carrying an extremely variable load, regulated to a remarkable degree, and many words of approbation were heard on all sides regarding its smooth operation.

The Fischer Foundry & Machine Company installed one of its 75-h.p. double-valve engines, running at 280 r.p.m. The company is making a specialty of this double-valve action, and now claims it can compete successfully with the Corliss type.

Sectional Steam Boilers

The New York Safety Steam Power Company, of New York city, the manufacturers of the Worthington water tube sectional steam boilers, is sending out a new catalogue in which are a number of interesting items on the construction and operation of sectional steam boilers.

Among the claims put forth in favor of this type are noticed the following: They are economical of valuable space, but at the same time are of liberal proportions in heating and grate surface; the furnace extends under the entire boiler and is of the proper height to permit the use of all kinds of fuel; the interior of the entire construction in every part and detail is readily accessible from the outside for examination, cleaning or repairs. Every tube used is lap-welded and of the best make, and each tube is straight; the heating surface and waterways are so arranged that the movement of the water contained in the boiler is constant and rapid.

The Peoria Electrolysis Case

Considerable advance was made last month in the trial before the United States Circuit Court in the case of the Peoria Water Works vs. Central Railway Company, which operates the electric railway system in Peoria. This case, it will be remembered, was brought by the water company against the railway company on account of alleged damages to its water pipes through electrolysis. The real complainant, it is said, is a large number of water companies who are interested in making this a test case. A number of electrical experts for the water company were examined last December and testified that the only remedy for electrolysis was the introduction of the double trolley system. The case of the railway company was not presented until last month, but in rebuttal of this testimony, the railway company presented the testimony of a large number of railway experts who testified that it was perfectly possible to eliminate all chances for electrolysis by good ground return, and that all reasonable precautions to accomplish this had been introduced by the defendant company. Among those who testified to this effect were Israel Lovett, of the Council Bluffs & Omaha Railway; Oscar Stiles, of the Omaha Street Railway; William Hand, of the General Electric Company, of St. Louis; J. C. Noe, of the General Electric Company, of Chicago; Edward M. Burch, of the Twin City Rapid Transit Company, of Minneapolis, and Albert B. Herrick, of New York.

Mr. Herrick, who was the chief witness for the defense, testified that he had made a thorough inspection of the railway system, had examined all the rail bonds and found only a very few defective joints, and that these were not at important points on the road. He had also made tests of the current returned to the station by the rails, and water pipes, and finding a large per cent passing by the water pipes, had made a further examination which disclosed the fact that the water company had placed a large number of its water gate boxes in very close proximity, and also in metallic contact to the rails of the electric railroad. These gate boxes were in metallic electrical connection with the rails and a very large current passed into the water pipe system, abundant to account for all the electrolytic action that was complained of. It was also brought out that these boxes had been placed in position by the water company and electrically connected to the rails after the tracks were placed in position, and that the location of the tracks and their position were made obligatory by the railway company by a city ordinance, but the location of the gate boxes was optional with the water company. Mr. Herrick also testified that from examinations he had made of lead service pipes used underneath the railroad track, and positive to the track near the power station, they permeated the earth between the rails and the track with lead sulphates which greatly reduced the earth's resistance, and this caused an influx of current to the paralleling water pipe system. Iron pipes are much better for this service as the oxide of iron has proved to act as an insulator to the pipe and does not afford a conductive medium in the path of current flow. He also testified that the amount of copper in the return circuit in the Peoria Railway was several times in excess of that in the positive trolley circuit, and that the connections of the negative feeder were made frequently and covered a large area. It was contended by the water company that the double trolley is the only way to relieve this electrolysis trouble and the Cincinnati example should receive general adoption by railroad systems.

Mr. Hand, of St. Louis; Mr. Noe, of Chicago, and Norman McD. Crawford, of Hartford, all testified in regard to their early experience of the double trolley which were not favorable to the imitation of Cincinnati's unique system.

Mr. Crawford's early experience made him abandon double trolley system and return to horses again, and all the evidence showed it to be a more expensive system to keep in repair. Mr. Lovett, of Council Bluffs, and Mr. Stiles, of the Omaha Street Railway, both testified as to having corrected all their troubles due to electrolysis by connecting the water pipes and rails together in affected districts.

Prof. Seaver, of Columbia College, brought out some very interesting facts regarding D. C. Jackson's early remarks in the electrolysis troubles, his lecture before the American Institute of Electrical Engineers taking exactly the same attitude as the experts for the railway company in the present case.

N. C. Draper, who was for three years electrical engineer for this property, gave in testimony all the conditions of the mechanical and electrical construction of the road, and due to his early efforts in bringing this road up to its present point of perfection regarding its negative circuits, the water company will have an extremely hard time in making any case on the grounds of wilful negligence or improper construction.

Judge Pinkney, who is conducting the case for the railroad company, has mastered the subject technically, and this, in connection with his well-known legal ability, makes the case extremely interesting from a technical point of view. The master also asked questions pertaining to the technical side of the subject, showing a technical knowledge very rarely found in court. This trial will be resumed on June 12, when the railway company will introduce further evidence in support of its case.

Meeting of the Southwestern Gas, Electric and Street Railway Association

The annual convention of this association was held in Austin, Tex., May 17 to May 19, and was a great success in every way. The attendance was large, the papers were valuable and interesting, and unusual enthusiasm was shown by all in attendance.

Among the papers presented was one by T. H. Stuart, of Waco, Tex., on "Summer Amusements for Street Railway Companies." In this treatise the author first reviewed the necessity of increasing the traffic on street railways in the South, and then gave a number of practical suggestions for the equipment and maintenance of pleasure parks. He laid particular stress upon the point that the first entertainment of the season given at any park should be a great success and well attended in order to start the enterprise aright. This is on the principle that people like to go wherever the crowd goes, and if the season can be opened with a large crowd in attendance the battle is more than half won. To this end great care should be exercised in selecting a first-class attraction for the opening, and in properly advertising it. The author points out the necessity of presenting nothing but perfectly respectable plays in order to induce women and children to visit the performances.

After suggesting the formation of a "theatrical circuit" of street railway companies, such as is now in operation in a number of places in the north, the writer touches upon the subject of an entrance fee, and the best way of getting revenue from the sale of privileges. He states that in his opinion visitors to the park that come by means other than the companies' cars should be charged the amount paid by those who use the street railway lines. The entrance to the theater, however, should be free, with a small charge for reserved seats. The writer concludes by stating that it has been the experience of the company with which he is connected that summer entertainments have been a source of considerable profit.

Other papers presented were: "The Item of Depreciation," by W. E. Hamilton, Shreveport, La.; "Meters," by W. E. Holmes, Austin, Tex.; "Transformers," by H. L. Monroe, Dallas, Tex.; "The Amount and Extent of Legitimate Investment in Electric Lighting Plants of Certain Capacities," by F. Fries, San Antonio, Tex.; "Art and Science of Selling Gas," by T. D. Miller, Dallas, Tex.; "A Model Plant Under Model Management; What Both Should Be Like," by J. F. Strickland, Waxahachie, Tex.

At the last day's session the following officers were elected for the next year: President, T. D. Miller, of Dallas; first vice-president, J. F. Strickland, of Waxahachie; second vice-president, C. A. Yeager, of Laredo; third vice-president, W. E. Hamilton, of Shreveport. The next meeting will be held at Waco.

A Visit to Schenectady

On Friday, May 26, the delegates to the convention of the National Electric Light Association, held in New York the last month, were the guests of the General Electric Company, who provided for them a most enjoyable trip to Schenectady. The visitors, who numbered about 170, traveled from New York upon a special train of eight palace cars, and reached Schenectady about noon, were guided about the works by the company's representatives.

Among the machinery which particularly interested the electric railway engineers of the party was a device for testing armatures, consisting of ingenius laminated horseshoe magnets. The poles of these magnets embraced an armature, and by means of an alternating winding in the magnet sets up an immense alternating field, which generates high e.m. f.'s in the windings and breaks down the insulation at any weak point. In another part of the works were seen two of the 990-kw. six-phase rotary converters for the Metropolitan Street Railway Company of New York, the first six-phase rotaries ever built; and in still another part four of the 100 gearless motors ordered for the Central London Underground Railroad. The armatures of these motors are mounted directly on the axles, with the wheels pressed on to either end, and present a peculiar appearance to eyes accustomed to geared machines. One of the 225-h.p. geared motors for the Paris-Orleans line was under test at the time of the visit. In the switchboard department were a large number of railway panels ready for shipment, some marked for cities in France.

Electric Locomotives in Practice and Tractive Resistance in Tunnels

An interesting and very extended paper on this subject was read May 4 by P. V. McMahon before the London Institution of Electrical Engineers, based on experiments and observations made by the writer on the locomotives and trains of the City & South London Railway. The extent of the paper forbids its reproduction in these columns in any comprehensive manner, but the following is an abridgement of the portion relating to tractive resistance:

Fig. 1 shows an outline of locomotive and train in the tunnel. The three locomotives used, Nos. 12, 15 and 17, were built to the same general design and over all dimensions, the only outward difference being in the shape of the cab, which in the case of 15 and 17 is bulged at the sides, instead of straight as in the case of No. 12.

LEADING DIMENSIONS

	Feet.	Inches.
Gage	4	8½
Over all height above rail level	8	5½
Over all length, buffer to buffer	14	0
Extreme width	6	10
Wheel base	6	0
Diameter of wheels	2	3
Width of tires	0	4¾

Each locomotive has two motors, the armatures of which are fixed directly on the axles. The motors are arranged in series, and the regulating gear consists of a reversing switch, which changes the armature connections, a simple rheostat switch in series with the motors, and a main break switch.

The remaining details are given in the following table, which makes comparison easier:

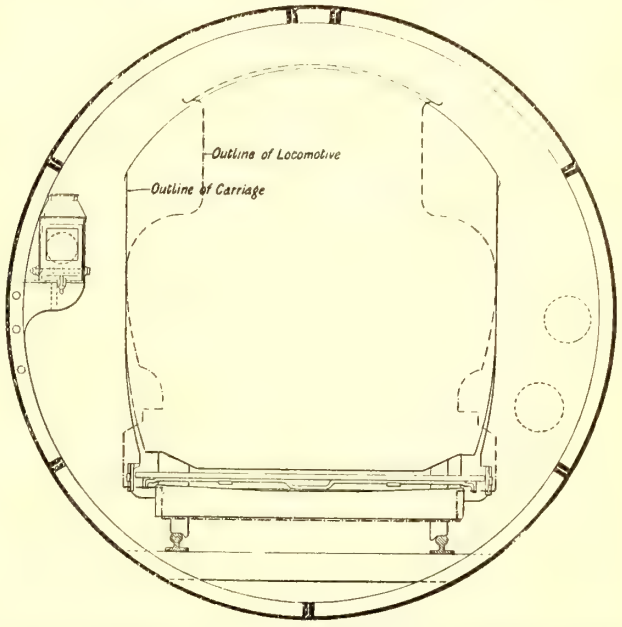

FIG. 1.—SECTION OF TUNNEL SHOWING OUTLINE OF LOCOMOTIVE AND CAR

	No 12 Locomotive.	No. 15 Locomotive.	No. 17 Locomotive.

Seating capacity	96 passengers	

Fig. 2 shows the result of a test made between Stockwell and the city, readings of the current, voltage, speed, and draw-bar pull being taken at five-second intervals. It will be noticed that the current at starting in this case is not over 100 amps., the current being kept low to avoid any jerk at starting, as it was not known at this stage what might happen to the diaphragm of the dynamometer. Although a value is given for the draw-bar pull at the first reading, the gage on the dynamometer did not show that any pull was being exerted for about one to two seconds after the current was switched on, showing that the locomotive takes an appreciable time to move. However, when the gage commenced to indicate, it gave varying values, the pointer sometimes going all over the scale with the current absolutely steady; by carefully watching the pointer during the interval it was possible to form a fairly accurate idea of the average pressure during each period. This jerking was most noticeable on down grades, as the pull of the locomotive seemed to be transmitted to the train by a series of jerks, the train and locomotive buffers alternately touching and separating. Upon an up grade the pull seemed to be more uniform, the buffers being nearly always apart. An inspection of Fig. 2 shows that the draw-bar pull curve follows the current pretty closely in shape, from which one might infer, that the dynamometer gave fairly accurate indications of what was going on between the locomotive and train. From the analysis of these curves the losses in the locomotive, and its draw-bar pull at starting and running were obtained, as well as the tractive force per ton of train hauled on the level, including air resistance.

LOCOMOTIVE LOSSES AND DRAW-BAR PULL AT STARTING

In order to arrive at the value of the draw-bar pull exerted by the locomotive on the level at starting, the starting periods at Kennington with 100 and 120 amps., and Elephant and Castle with the same currents, will be considered; these stations are chosen to avoid the errors (or uncertainties) introduced into the dynamometer readings by a quick down grade. In each of the four cases the values of the dynamometer reading, the tractive force due to gravity, and the tractive force due to acceleration were taken from the plotted curves, at five-second intervals, and reduced to the level at a constant speed. Thus at Kennington (curve Fig. 3) at five seconds after starting the draw-bar pull as shown by the dynamometer was 1075 lbs., the tractive force due to acceleration plus or minus gravity was 201 lbs., and as this force did not appear at the draw-bar, but was given out by the locomotive at the tread of the wheel, it must be added to the draw-bar pull, consequently the total tractive effort which should appear at the draw-bar at a constant speed on the level would be 1276 lbs. for a current of 105 amps. In the same manner at the tenth-second interval the draw-bar pull was 1075 lbs., the tractive force due to acceleration plus or minus gravity was 345 lbs., giving 1420 lbs at the draw-bar at a constant speed on the level for a current of 100 amps.; in the same way the tractive efforts at the draw-bar at the fifteenth and twentieth-second intervals were 1467 lbs., and 1596 lbs. for a current of 100 amps. To facilitate the analysis of these curves during the starting period, both as regards locomotive losses and tractive effort per ton of train at starting, the curves, Figs. 3 and 4 (from the Kennington and from the Oval curves) are plotted to a distance scale in Figs. 5, 6, 7 and 8. The value of gravity for half a coach on the level and half on the grade could then easily be allowed for. Plotting the values of speed and tractive force at the draw-bar at constant speeds on the level, we get two curves showing the tractive effort for 100 and 118 amps., at speeds of from 0 to 9 miles per hour. The value at 0 is taken from the static draw-bar pull. From these two curves it would seem as if the effective tractive force increased, or locomotive losses decreased, with the speed until the latter reached about 9 miles per hour.

LOCOMOTIVE LOSSES AND DRAW-BAR PULL WHEN RUNNING

To arrive at the draw-bar pull on the level exerted by the locomotive for speeds of 9 miles per hour and upwards, for various currents, the experimental runs between Stockwell and the Eleplant, and the Elephant and Stockwell, were analyzed as before

explained, but in this case the area of the speed, current, draw-bar pull, and the tractive force due to gravity and acceleration curves, Figs. 2, 3 and 4, were measured, and from these the average values were obtained as follows: Between Stockwell and the Oval the average draw-bar pull was 268 lbs. for an average current of 36.8 amps. at an average speed of 18.4 miles per hour (during the running period). The average tractive force due to acceleration, plus or minus gravity, was 8.36 lbs., leaving 259.7 lbs. as the tractive force at the draw-bar of the locomotive on the level at a constant speed. From the Prony brake test the tractive force at the tread of the wheel for a current of 36.8 amps. was 340 lbs., leaving 80 lbs. as the locomotive losses, in which are included journal and rail friction, and air resistance. Plotting the tractive force and current from these and other tests, the curve approximates a straight line with a fair amount of accuracy. From this curve it appears as if the locomotive losses increased with the current. This increase must be due to journal or rail friction, as the air resistance is certainly greater at a high than at a low speed, and the smaller current corresponds to a higher speed. There does not seem to be any definite relation between the locomotive losses and the speed as in the case of starting from rest.

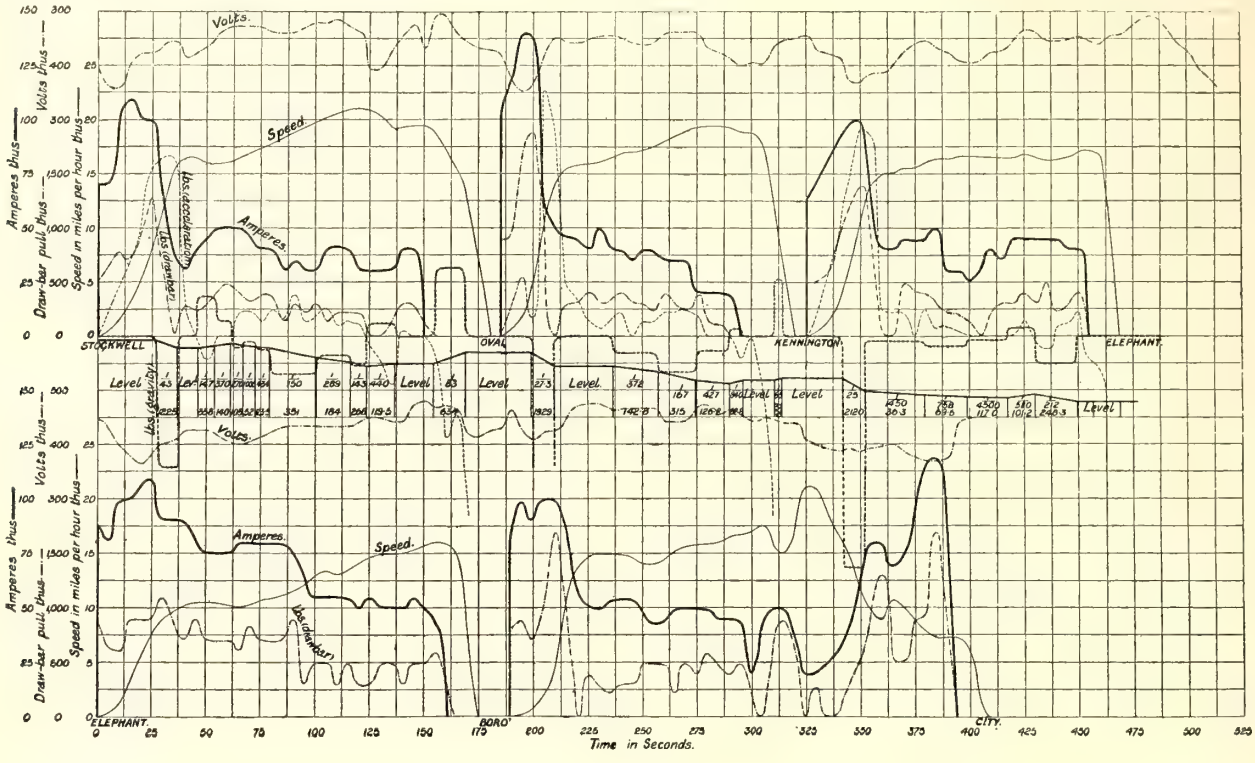

FIG. 2

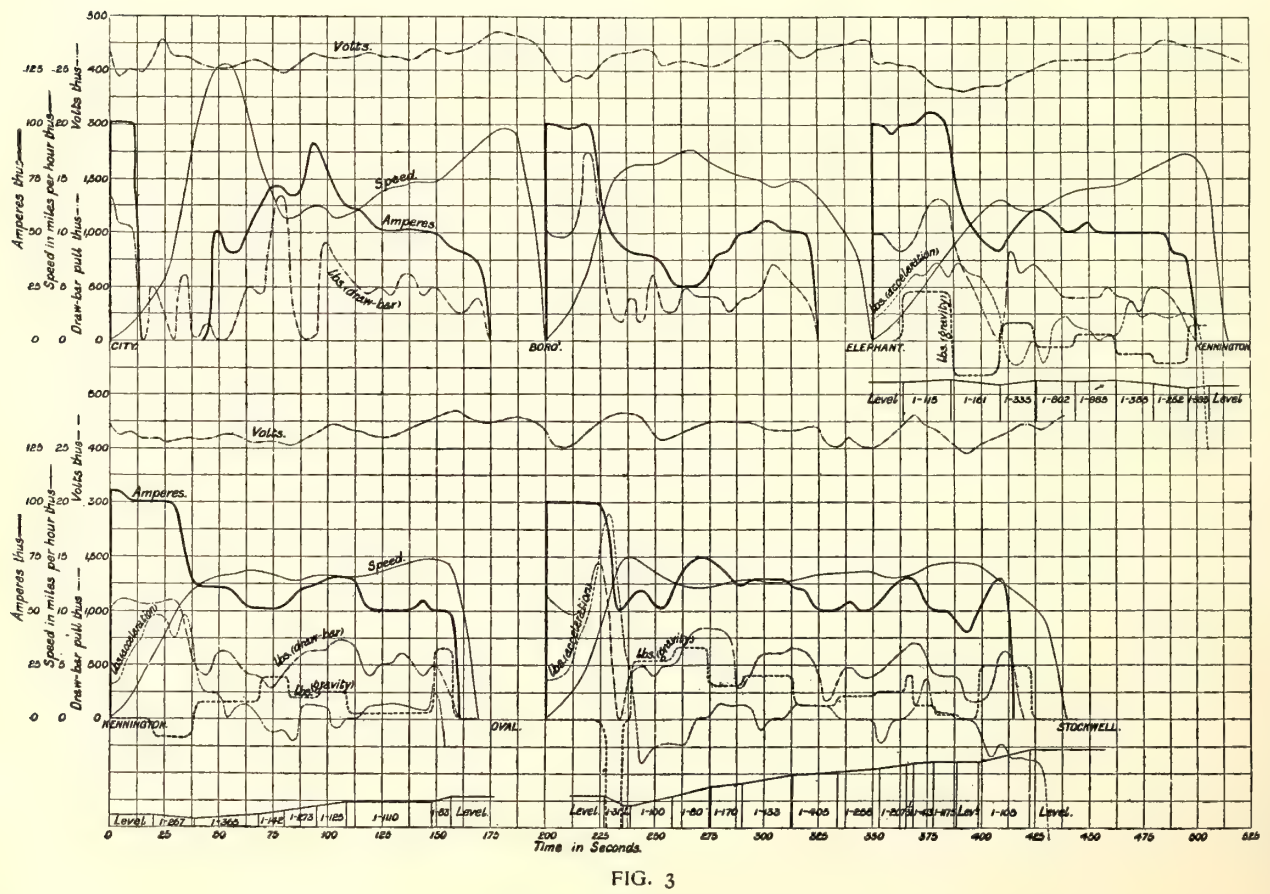

FIG. 3

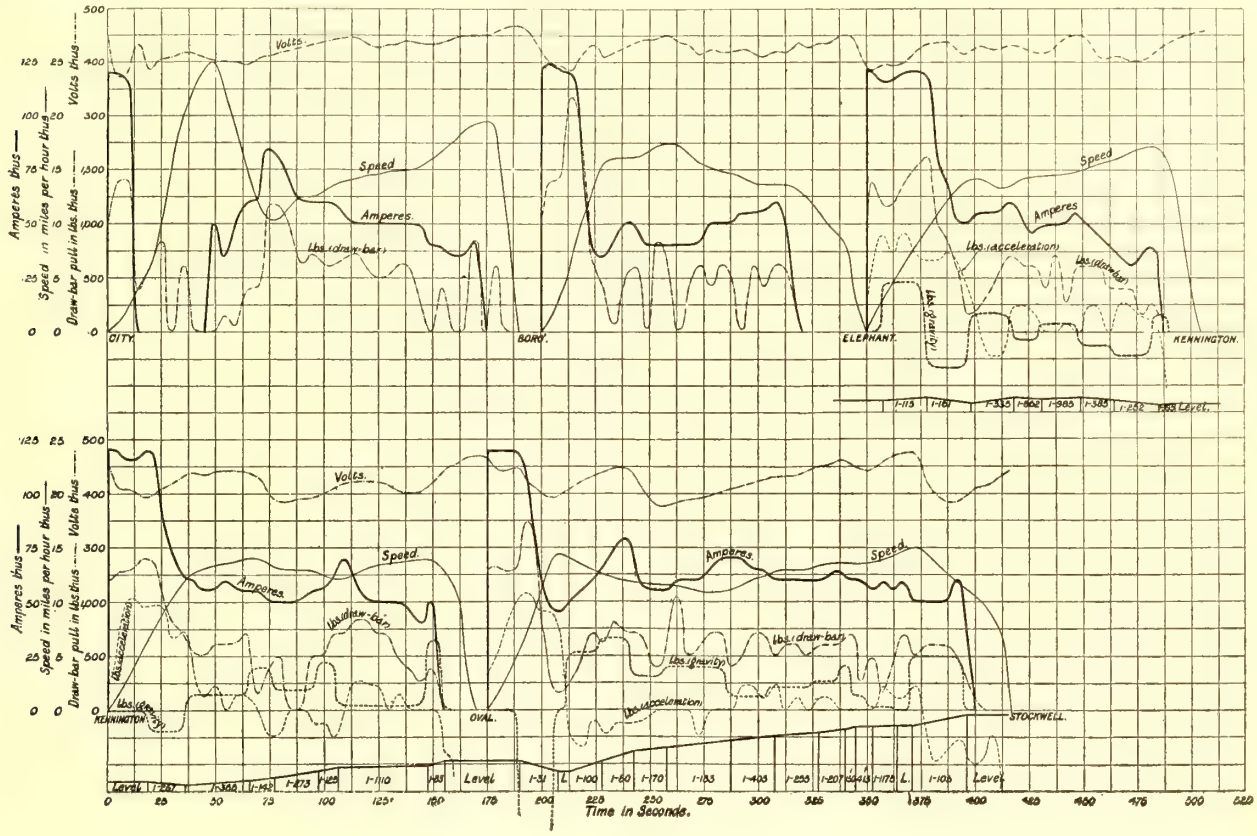
TRACTIVE RESISTANCE PER TON OF TRAIN

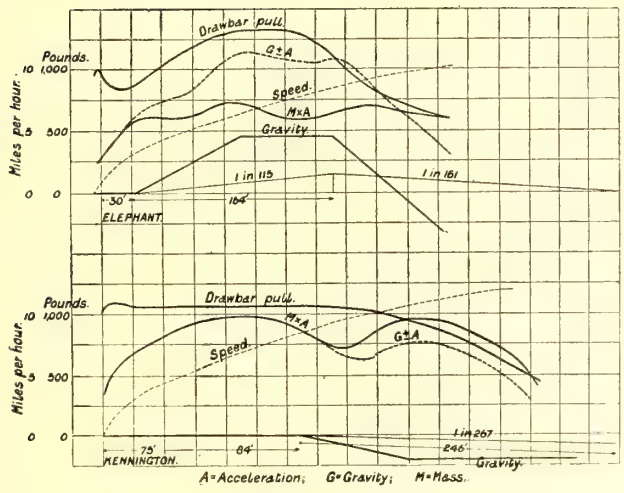
From Figs. 2, 3 and 4, the tractive resistance per ton of train, in-

cluding air resistance, was also arrived at. In arriving at the tractive force per ton at starting, it was necessary to consider the length of the train in passing from one gradient to another, and this was allowed for in the following manner: The speed, draw-bar pull and tractive force due to acceleration were plotted to a distance basis from the calculated distance traveled; the gradient was then plotted and the position of each coach on the gradient (up or down) determined at each interval; the tractive force due to gravity was then obtained and plotted, and so on until a speed of about 10 miles an hour was reached. This is seen more easily by reference to Figs. 5, 6, 7 and 8. Here it may not be out of place to consider in detail what takes place in a starting period, say from Elephant and

The tractive force in lbs. per ton on a level is plotted in Fig. 9, and gives the first part of the curve shown there. The points of this curve above 9 miles per hour are the average values obtained from the running periods between Stockwell and the Elephant and Castle up and down roads, and are arrived at from the dynamometer observation curves, Figs. 2, 3 and 4, in a manner similar to that explained above.

The tractive force per ton in the case of the two-coach train came out rather higher, being 21.1 lbs. per ton for an average speed of 16.5 miles per hour. This slight increase may be due to both trains having the same area of cross-section exposed to the air, while the total weight in the second case is less than in the





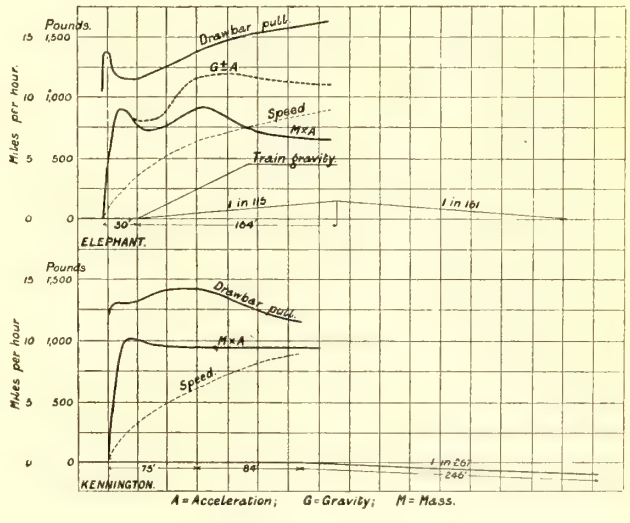


FIG. 4

FIGS. 5 AND 6

FIGS. 7 AND 8

Castle, Fig. 5. At the moment of starting the front end of the train was on the level, and 30 ft. from an up gradient of 1 in 115. After traveling about 60 ft., one coach was completely on the incline; in this position the effect of gravity was 152 lbs.; when another 30 ft. had been passed over, two coaches were on the incline, and the value of gravity was 304 lbs. When the whole train was on the incline the gravity curve ceased to rise and ran parallel to the base until the down grade of 1 in 161 was reached by the first coach. The down gradient was analyzed in a similar manner, and from the result the corresponding part of the gravity curve was plotted.

first. Again, the skin resistance should be less in the second case on account of the train being shorter. In the third experiment the current was shut off earlier, and thus the speed was maintained almost constant until it was switched on again; the resistance per ton in this case came out at 11 lbs. for an average speed of 15.86 miles per hour.

EFFECT OF CURVES

To arrive at the additional resistance offered by the curves on the line, the observations from which the tractive force per ton was obtained were further analyzed in the following manner: The

position of the curve in the section being known, the exact time when the train was passing over the curve was found as already explained, for the gradient, the draw-bar pull, tractive effort due to gravity and acceleration were taken from the respective plottings for the particular section, and in this manner the total tractive effort per ton on the level at a constant speed was obtained; deducting from this the tractive resistance per ton already found at that particular speed, the result gave the additional resistance due to the curve. Although there are several sharp curves their length is small and it was difficult to get accurate results, as in some cases the length of curve was not greater than that of the locomotive and train. The most consistent results were obtained on the curves between the Borough and Elephant stations, and between the Elephant and Kennington stations. The first curve has a radius of 390 ft., and the average of three sets of observations gave 27.9 lbs. per ton at 16.5 miles per hour, the tractive force per ton on the straight and level road being 12.75, leaving 15.15 lbs. per ton due to the curve alone. The next curve has 540 feet radius, and the

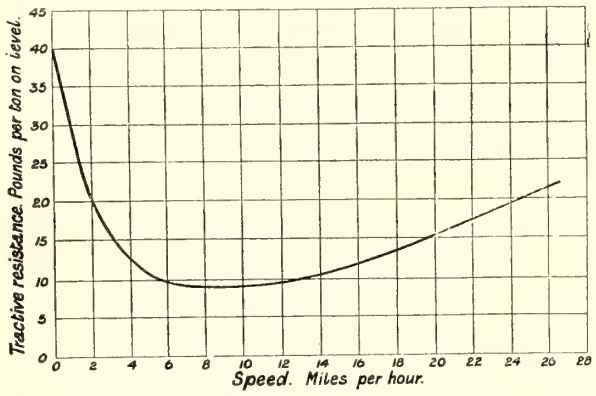

FIG. 9.—CURVE SHOWING TRACTIVE RESISTANCE PER TON AT VARIOUS SPEEDS

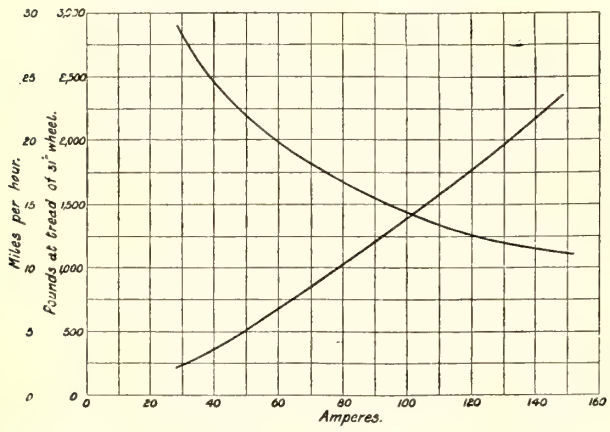

FIG. 11.—CHARACTERISTIC CURVES—NO. 19 LOCOMOTIVE

average of six sets of observations gave 22.6 lbs. per ton, at 13.5 miles per hour, that on the level straight road being 11.3 lbs., leaving 11.3 lbs. due to the curve.

It is, perhaps, worth mentioning that there is a guard-rail on each of these curves, which, although in good condition and very smooth, no doubt adds to the resistance.

ACCELERATION

After an extended consideration of electric locomotive design, the writer takes up the question of acceleration and speed. On this he says:

From practice it appears that to run a level section 2700 ft. long, 130 seconds is a convenient time to meet ordinary traffic requirements. Given this basis, the lowest speed at which it is possible to run the section is 14.25 miles per hour, assuming infinitely quick positive and negative acceleration; or, in other words, entering the section at full speed and running through without stopping. This is, of course, an impossible condition, but the nearest approach to it is to get up to full speed in the shortest possible time, and to stop in the same manner. It has been shown that a negative acceleration of 1.46 ft. per second per second, corresponding to stopping in twenty seconds from a speed of 20 miles per hour, does not cause discomfort to the passengers and is not too hard on the brakes and wheels. In practice we sometimes get an acceleration of 2 ft. per second per second or more, but 1.46 ft. per second will be taken as the maximum in this investigation.

If for practical reasons it is not desirable to adopt a higher negative acceleration than 1.46 ft. per second per second in bringing the train to rest, there is clearly no need to try and get a higher positive acceleration at starting. Adopting this acceleration for starting and stopping, we find that the speed at which the locomotive and train must run, after the acceleration is attained is 16.25 miles per hour. This is made clear by Fig. 10. Here the ordinates represent the speed in miles per hour, and the abscissæ the time in seconds. A series of speed curves can be obtained which will enclose the same area, and consequently any curve of this series will enable the run to be accomplished in the specified time. Stopping from 20 miles per hour in twenty seconds was adopted as the negative acceleration in all cases, and positive accelerations of 1.46, .974, .73, .584, .487, and .417 ft. per second per second were also adopted, corresponding to starting from rest and attaining speeds of 20 miles per hour in 20, 30, 40, 50, 60, and 70 seconds, respectively. A line was drawn parallel to the abscissæ from each of the above acceleration lines (if they may be so called), enclosing the same area in each case; this gave the speed at which the train must run, after attaining its acceleration, until the brakes are applied.

With a uniform acceleration of 1.46 ft. per second per second during the starting period, we see from Fig. 10 that the speed during the running was 16.25 miles per hour until the brakes are applied. The next speed curve, with its acceleration of .974 ft. per second per second during the starting period, requires a speed of

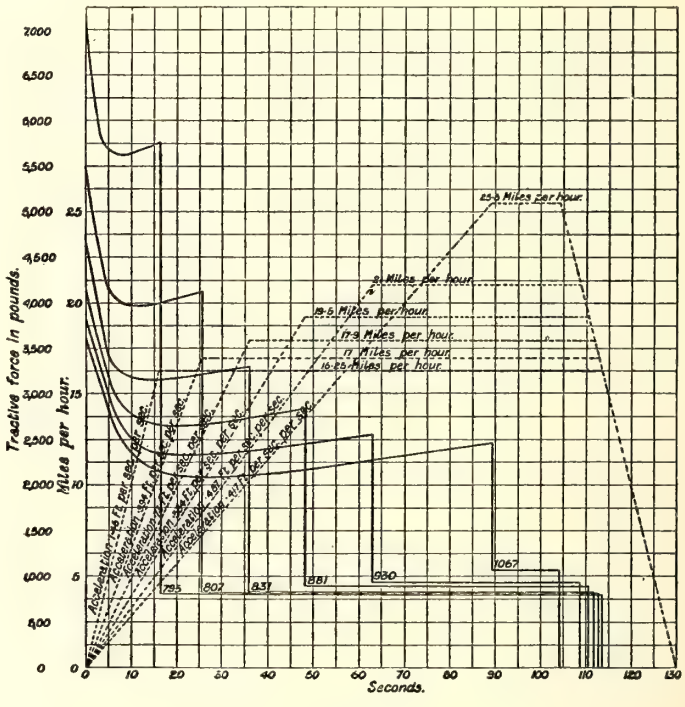

FIG. 10.—DIAGRAM OF ACCELERATIONS AND TRACTIVE FORCES

17.0 miles per hour during the running period. For accelerations of .73, .594, .487, and .471 ft. per second per second, during the starting periods, the respective speeds during the running periods, and until the brakes are applied, are 17.9, 19.5, 21.0, and 25.5 miles per hour. It is evident from this that the more quickly the train attains full speed, the slower the running speed will be. And as will be seen from a study of the tractive force curves, corresponding to the various speed curves, the slower the running speed, the lower the kinetic energy stored up at starting, and taken out again by the brakes in stopping.

Turning now to the tractive force required to obtain the various conditions laid down above, we see (Fig. 10) that to give the train and locomotive an acceleration of 1.46 ft. per second per second, a force of 4915 lbs. is required, and this must be kept up for 16.3 seconds until a speed of 16.25 miles per hour is attained. To this must be added the tractive resistance taken from Fig. 9 at every interval, as already explained. The total tractive force, then, exerted by the motors at the moment of starting is 7125 lbs., dropping to 6250 lbs. at 2 miles per hour, 5750 lbs. at 4, 5650 lbs. at 6, and 5625 lbs. at 8 miles per hour; it now commences to rise again, and is 5650 lbs. at 10 miles per hour, 5700 lbs. at 12, 5725 lbs. at 14, and 5750 lbs. at 16 miles per hour; when 16.25 miles per hour is reached, it drops to 795 lbs., this being the tractive force necessary for running at that speed.

The remaining five tractive force curves were arrived at in a similar manner, and need no further explanation. Returning for

a moment to the tractive force curve for an acceleration of 1.46 ft. per second per second, we see that 4975 lbs., acting for 16.3 seconds, that is 81,100 pound-seconds, were required for acceleration, and if this number is multiplied by the feet passed through in the

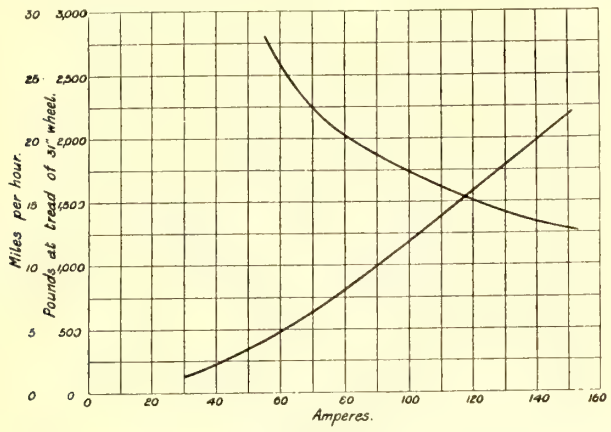

FIG. 12.—CHARACTERISTIC CURVES—NO. 20 LOCOMOTIVE

specified time, the result is foot-pound-seconds. It is, however, more convenient for present purposes to speak of pound-seconds or the area enclosed by the tractive force curve. When the tractive resistance is added to the above, the pound-seconds for the starting period are 95,220, and the running period requires 77,400 pound-seconds, making a total of 172,620 pound-seconds for the run.

The table in the next column gives the results of the six sets, and is self-explanatory.

This table shows the enormous advantage to be gained by adopting the highest acceleration compatible with the practical details of motor design. It fortunately happens, however, that we have a fairly large choice without increasing by more than 6 per cent the total energy drawn from the source of supply. In designing a locomotive, it is not of very great importance, or at least it will not affect the final result to any great extent, if the sharp peak of the tractive force curve at the moment of starting is averaged over the whole period of starting. This will reduce the size of the motors and the tractive force that they must give out during the first few seconds, and will prevent the speed curve from rising in a perfectly straight line as shown. Thus in the case of tractive force curve for an acceleration of 1.46 ft. per second per second, the tractive force instead of being 7125 lbs. at the moment of starting,

Seconds to Attain 20 Miles per Hour.	Acceleration in Feet per Sec. per Sec.	Lbs., Secs. for Acceleration Only.	Lbs., Secs. for Acceleration and Tractive Resistance.	Difference Due to Tractive Resistance.	Lbs., Secs. for Running Period.	Total lbs., Secs. for 2,700 Ft. Run.	Percentage Increase Due to Acceleration.	Percentage Increase in Total lbs., Secs.
20	1.46	81,100	95,220	14,120	77,400	172,620	Stand'd	Stand'd
30	.974	84,600	106,350	21,750	70,600	176,950	4.32	2.51
40	.730	89,400	119,540	30,140	63,150	182,690	10 24	5.84
50	.584	95,600	136,140	49,540	55,200	191,340	17.87	10.86
60	.487	104,600	158,870	54,210	42,650	201,460	29.0	16.7
70	.417	126,800	204,300	77,500	16,070	220,370	56.4	27.65

may be reduced to an average of 5839 lbs. over the starting period.

Fig 10 and the table of results show the way in which to apply the tractive force to obtain economical working.

Since the completion of the portion of the paper given above, some two and one-half years ago, three new locomotives have been

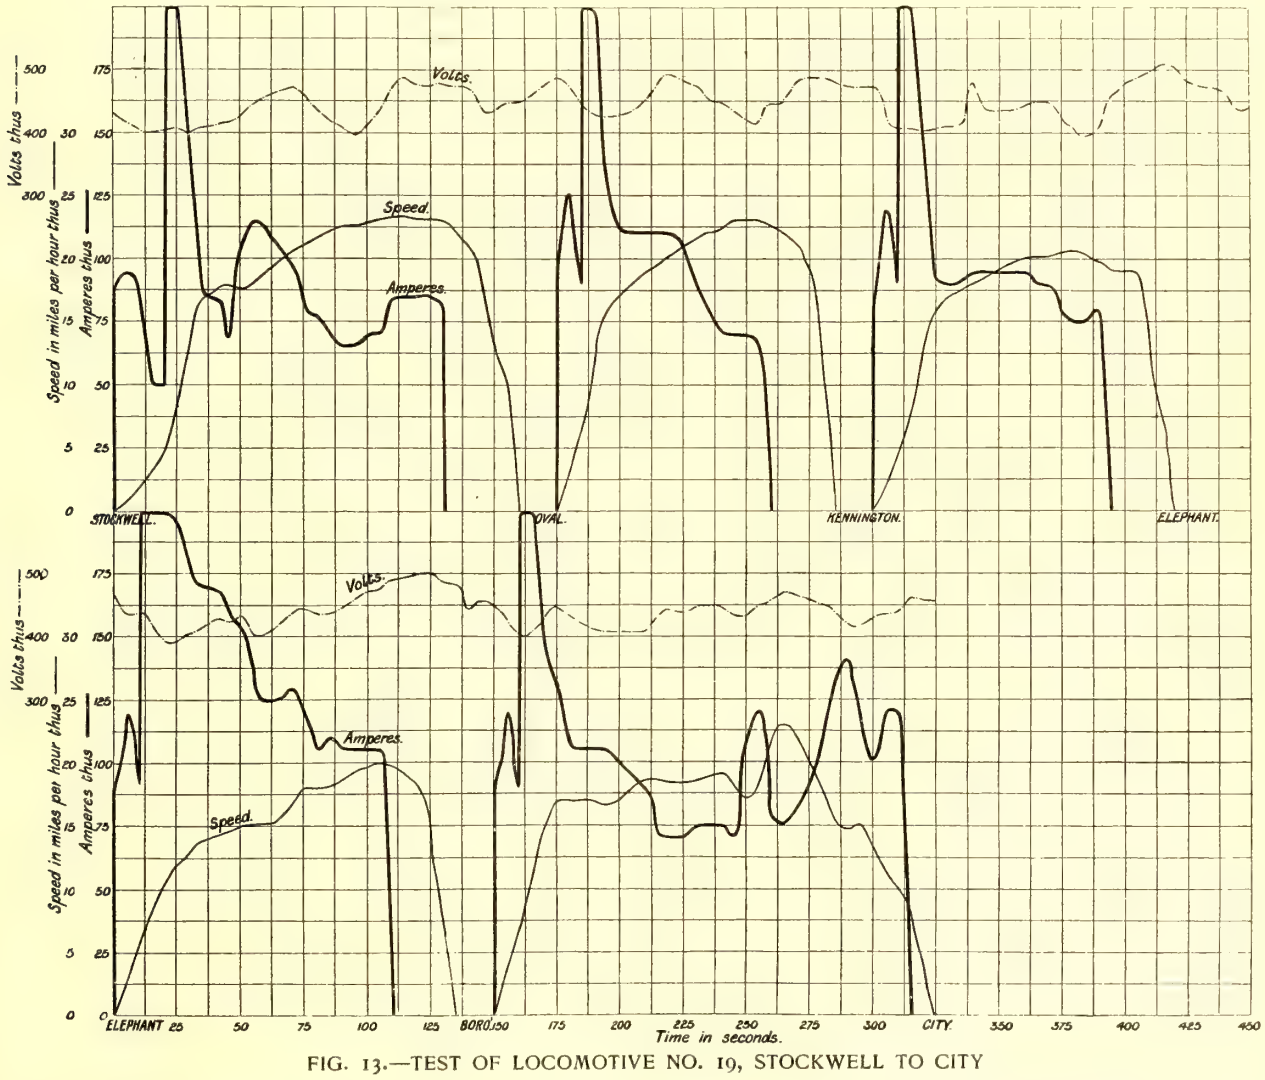

FIG. 13.—TEST OF LOCOMOTIVE NO. 19, STOCKWELL TO CITY

added to the rolling stock of the City & South London Railway, and twelve more are now in course of construction.

DESCRIPTION AND TESTS OF LOCOMOTIVES

Locomotives 19 and 20.—In view of the heavier trains, etc., it was decided to build more powerful locomotives. The size of the locomotive cab was practically limited to the same over all

dimensions as the old locomotives on account of local conditions, and it was therefore necessary to get larger motors into a cab of the same size. In the old locomotives the magnets are very close to the working conductor, and to get more clearance a wheel 31 ins. in diameter was adopted instead of a 27 in. wheel. This also allowed an armature of larger diameter to be used. Each locomotive is fitted with two motors of the four-pole type, the armatures having slotted cores and drum winding. The series-parallel method of control is adopted and, in addition to storage reservoirs for compressed air for the Westinghouse brake, independent electrical air-compressors are used. The weight of the locomotive complete is about 12¼ tons.

The characteristic curves of the motors of locomotives Nos. 19 and 20 are given in Figs. 11 and 12, from which it will be seen that the tractive force per ampere is considerably higher than in the case of the old locomotives. A "performance diagram" for locomotive No. 19, between Stockwell and city, is given in Fig. 13. This test was made with a three-coach train, and as the locomotive

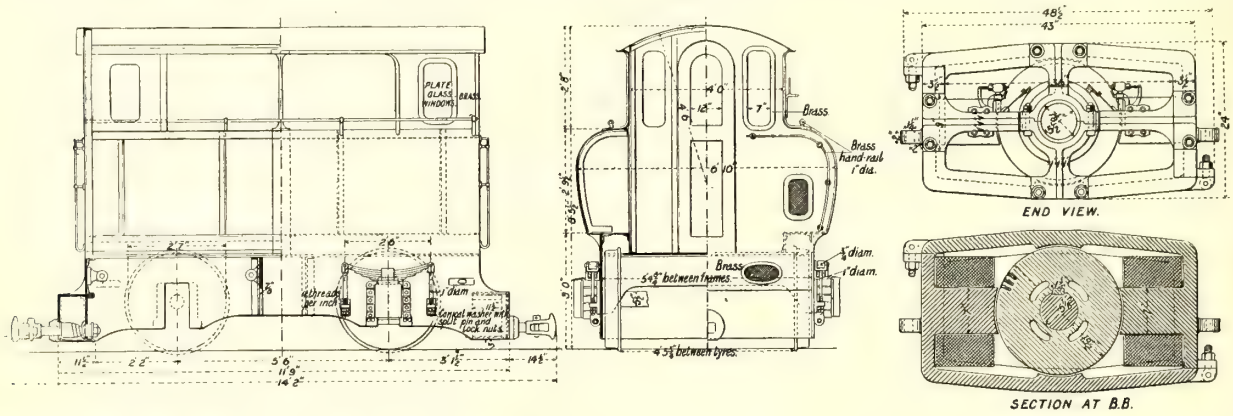

FIG. 14.—SIDE AND END ELEVATION OF LOCOMOTIVE NO. 21

was designed for a four-coach train service, it was not working under most economical conditions. The results of the tests with these locomotives, together with the previous tests of Nos. 3 and 12 locomotives, are given in the following table in kw.-hours per "ton-mile." It will be noticed that while the energy per ton-mile is practically constant, there is an increase in the average speed:

No. of Locomotive.	Kilowatt-hour per Ton-Mile.	Average Speed in Miles per Hour.
12	.0515	13.62
3	.0558	15.60
19	.0552	15.86
20	.0552	16.65

No. 20 locomotive gives the highest average speed, and it may be mentioned here that when this locomotive was ordered the author was in a better position to specify the requirements than when the order for No. 19 locomotive was placed. The latter locomotive was nearing completion before the former was required, and when the plans of No. 19 were prepared, the author had not gone so far into the question of locomotive design.

Locomotive No. 21.—The design and details of this and the remaining eleven locomotives were based upon the result of the tests and deductions already mentioned.

The general appearance and leading dimensions of the cab are given in Fig. 14, from which it will be seen that the wheels are 31 ins. in diameter, and the wheel base is 5 ft. 6 ins. The motors are so arranged that the floor of the cab is level, and the driver has considerably more room than in the old locomotives. The steel cylinders forming the air reservoirs are arranged one on each side of the cab, and have a total capacity of 18 cu. ft. Under the reservoir on one side are fitted the Westinghouse brake cylinder and brake gear connected therewith, and the electrically driven air compressor; while on the other side, the switchboard containing the series-parallel controller, reversing switch, motor cut-out, and main switches and fuse are placed; the regulating resistances are fitted directly under the air reservoir on this side, close to the controlling arrangements. The drawing, Fig. 15, gives the general arrangement and details of the motor, which is of the four-pole type, with the field magnet coils on the horizontal poles. The magnet is split across the diagonal corners, and the brackets carrying the motor bearings are divided in halves, so that each part of the magnet carries its bracket with it when the halves are separated to get the armature out. The armature is drum wound with the conductors in slots. The characteristic curves of the motor are given in Fig. 16. A description of the controlling arrangement and connections is added below. The weight of the locomotive complete is about 12¼ tons.

A "performance diagram" of this locomotive hauling a four-coach train is given in Fig. 17, from which it will be seen that the time taken to run a level section 2700 ft. long is 130 seconds, the current being shut off 74 seconds after starting, the locomotive coasting for 41.5 seconds, and the brakes being then applied. The watt-hour consumption for the section is 1360. If the current is kept on until the brakes are applied the section can be run in 122 seconds, the watt-hours being 1650.

METHOD OF CONTROL

In electric traction with separate locomotives there are conditions slightly different from those where motor cars are used. In coupling up the locomotive to the train the driver cannot always stop in the exact position to enable the coupling to be attached; and it is often necessary to move the locomotive through a mere fraction of an inch. Experience has shown that to avoid

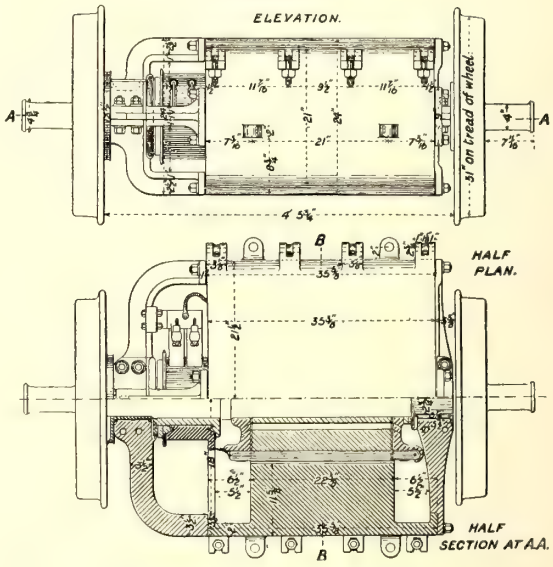

FIG. 15.—MOTOR OF NO. 21 LOCOMOTIVE

bad flashing on the controller contacts when a current of, say, 100 amps. is suddenly switched on and off before the motors have made a fraction of a revolution, the regulating resistance should be divided into a larger number of steps. The plain rheostat switch used on the old locomotives answered this purpose admirably, and in adopting a series-parallel controller this object was kept in view. Further, the drivers were used to this class of switching-gear, and a series-parallel controller, retaining the old form of rheostat switch, was developed. This series-parallel controller consists of two switches operated by a single handle, that part of the controller which puts the motors into parallel being moved only at predetermined points. Magnetic blow-outs, or other spark-killing devices, are not used, the motors being put into parallel practically without any flashing on the contacts, and not being put back into the series position again until the current is switched off the locomotive. Fig. 18 shows the connections of this arrangement. It is not necessary to lock the paralleling part of the switch to avoid short-circuiting when a motor is cut out of circuit, this contingency being provided for in the switch used for cutting out a motor. The contacts for shunting the field at starting are shown alongside the parallel contacts.

This controller was first used on No. 3 locomotive in the latter part of 1897, and has since given excellent results, having run over

22,000 miles in every-day use. It is fitted to No. 20 locomotive, No. 19 being fitted with the Electric Construction Company's controller, similar to the type used on the Liverpool Overhead Railway. The reversing switch which reverses the direction of the current in the armatures is quite independent of the series-parallel controller, and is mounted on a separate base; there is no mechanical interlocking, as in practice it has not been found necessary. A main switch and fuse is also fitted on the same board.

COASTING

In comparing the calculated "performance diagrams" with those actually obtained from tests on the line, a difference in the method of applying the brakes will be noticed. In the calculated diagrams the brakes were assumed to be applied at the instant the current was shut off, this assumption making the calculation easier. This method is not carried out in practice, as the current is shut off earlier and the locomotive allowed to coast before the

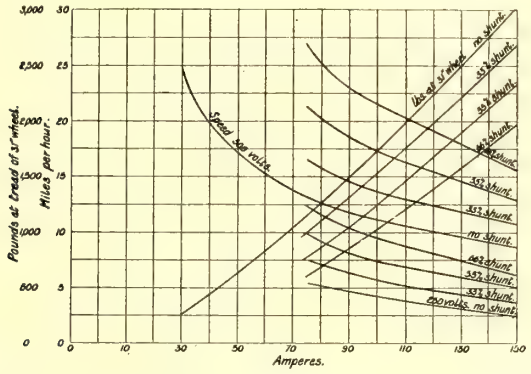

FIG. 16.—CHARACTERISTIC CURVES OF NO. 21 LOCOMOTIVE MOTOR

brakes are applied. The amount of coasting allowable varies with the gradients in the section.

While on this point it may be interesting to give the result of two round trips with No. 19 locomotive. The first portion of the run is plotted in Fig. 13. The time taken for the complete journey was .396 hour, and the average speed 15.86 miles per hour; the energy consumed was 13.32 kw.-hours, or .0552 kw.-hour per "ton-mile." In the second run the current was shut off earlier in each section, with the result that the time taken for the complete journey was .41 hour, and the average speed 15.35 miles per hour; the energy consumed was 12.214 kw.-hours, or .0507 kw.-hour per ton-mile. The average speed in the second case was 3.2 per cent and the energy consumption was 8.15 per cent less than in the first case.

On the up journey there is a continuous down grade to the Elephant station, and from the Elephant to Stockwell a continuous up grade. The average speed from Stockwell to the Elephant in the first and second trips was practically the same (the difference being less than 1 per cent), while there is a decrease of 10.95 per cent in the energy consumption in favor of shutting off the current earlier.

On the down journey from the Elephant to Stockwell the average speed on the first trip was 15.3 miles per hour, and on the second 14.5 miles per hour, showing a decrease of 5.2 per cent, while the energy consumed exhibits a decrease of only 8.25 per cent in favor of coasting. It will be seen from this that the advantages of coasting on an up grade are not comparable with those to be obtained by following this method on a down grade.

RAPID ACCELERATION

The author is aware that rapid acceleration for short sections is very desirable, but in his opinion a point can be reached long before the tractive force becomes equal to the adhesion, when it will not pay.

Apart from its influence on the comfort of passengers, very rapid acceleration necessitates the use of very powerful and heavy motors, and consequently leads to an increase in the ratio of the weight of the empty to that of the fully loaded train. Moreover, the starting current is increased several fold when rapid acceleration is used, and, of course, with it the cost of feeders and generating plant.

For the same section the kilowatts per "ton-mile" will be decreased, but the ratio of the average to the maximum demand upon the generating station will increase, and unless a very careful time table is followed in starting the trains, the generating plant must work on the average considerably under loaded. This remark does not apply with such force where a very large number of trains are running as where only a small number are in service. Again, with a rapid acceleration, the wear and tear of the rolling stock will be heavier.

The following example, worked out for a four-coach train and locomotive weighing 49 tons, running in a section 2700 ft. long, will be considered. The time to run the section is taken the same as before, viz., 130 seconds, giving an average speed of 14.25 miles

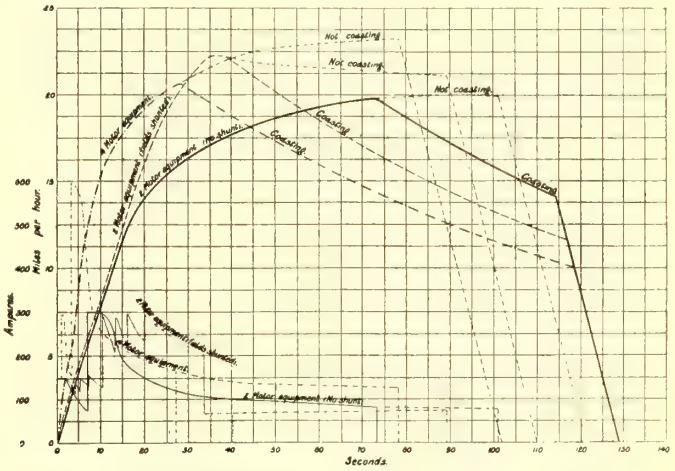

FIG. 17.—PERFORMANCE DIAGRAMS, 2 AND 4 MOTOR EQUIPMENTS

per hour. In the first and second cases "performance diagrams" are worked out for No. 21 locomotive, which has two motors, as already described. In the third case a locomotive is taken with four motors exactly similar to those of No. 21 locomotive; the seating capacity is, however, less, as the same total weight is taken, viz., 49 tons. The three "performance diagrams" are plotted in Fig. 17.

In the first case (2-motor equipment, no shunt) the speed-curve shows that a speed of 12.5 miles per hour would be attained in sixteen seconds, which is equivalent to a uniform acceleration of 1.14 ft. per second per second. After this point is reached the speed-curve bends over rapidly, a speed of 19.75 miles per hour being attained 74 seconds after starting; at this point the current is switched off and the locomotive and train are allowed to coast for 41.5 seconds; the brakes are then applied, and the run is completed in 130 seconds, the energy consumption being 1360 watt-hours, or .0540 kw. per ton-mile.

In the second case the starting current is limited to 150 amps.

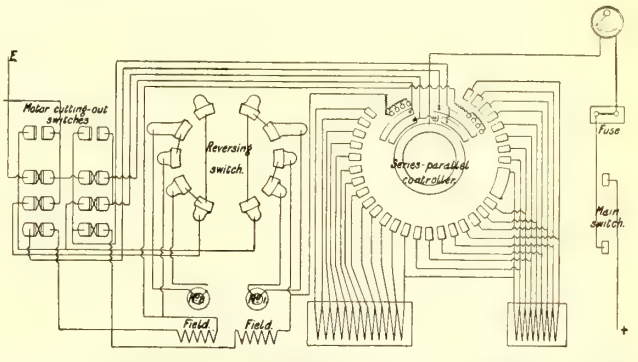

FIG. 18.—DIAGRAM OF CONNECTIONS OF SERIES PARALLEL CONTROLLER

as before, and when the value of the current flowing begins to drop the fields are successively shunted until a speed of 8 miles per hour is attained; the motors are placed in parallel at this point, and the current is limited to 300 amps., the fields are shunted as when in series, and when a speed of 22 miles per hour is reached the shunt is disused. Here the speed-curve bends over quickly and begins to drop, the motors being then in parallel with their full fields. At 40.75 seconds from starting the current is switched off, and the locomotive and train are allowed to coast for 67.25 seconds; the brakes are then applied, and the run is completed in 130 seconds as before. From the curve it will be noticed that a speed of 17.5 miles per hour is attained in twelve seconds after starting from rest, and this is equivalent to a uniform acceleration of 2.13 ft. per second per second. The energy consumed for the run is 1081 watt-hours, or .0430 kw.-hour per ton-mile.

We will next consider the third case, with the four-motor equipment. Starting with the four motors in series and 150 amps. as

before, at 2 miles per hour, the motors are placed two in series and these in parallel, the current being limited to 300 amps. At 6 miles per hour the four motors are placed in parallel and the current is limited to 150 amps per motor, or a total of 600 amps. This peak quickly falls, and in five seconds from placing the four motors in parallel the current drops to 300 amps. At 27.5 seconds after starting the current is shut off, coasting commences and continues for 92.5 seconds, the brakes being then applied, and the run completed in the required 130 seconds. The energy consumed is 946 watt-hours, or .0377 kw.-hour per ton-mile. In nine seconds from starting a speed of 15 miles per hour is attained, corresponding to a uniform acceleration of 2.43 ft. per second per second. From 15 to 20.5 miles per hour the speed-curve bends over more quickly than in the second case considered, but if the fields had been shunted the acceleration could have been maintained uniform until a higher speed was attained.

If in the above cases coasting were not resorted to, but the current were kept on until the brakes were applied, and the negative acceleration in each case were 1.46 ft. per second per second, the respective times required to run the 2700 ft. section would have been 122, 111, and 103 seconds, the average speed would have been 15.07, 16.0, and 17.87 miles per hour, and the energy consumed .0659, .0628, and .0745 kilowatts per ton-mile.

Having arrived at the effect of rapid acceleration upon the energy consumed per "ton-mile," we will now consider its effect upon the capacity of the generating station, feeders, etc.

By way of illustration let us assume ten sections of 2700 ft. each, and allow ten seconds at each station. Take as a basis a two-minute service, or thirty trains per hour leaving the terminal station. With the four-motor equipment, the seating capacity would be something like 20 per cent less than with the two-motor equipment, on account of the weight of the train and locomotive being taken as the same in each case.

Adopting the first "performance diagram" considered, viz., the two-motor equipment (coasting), as the standard, the following comparison is interesting and instructive. The time required to run the ten sections is 23.15 minutes, including stopping at stations. The maximum output of the generating station would be 2715 amps., and the average about 810. Thus the average is about 29 per cent of the maximum. With the four-motor equipment (coasting), where we get a high rate of acceleration, and a low energy consumption per ton-mile, the time to complete the run is the same, but the maximum output, arrived at as before, would be something like 5640 amps., the average being about 565 amps. Here the average is only about 10 per cent of the maximum, and any gain in the low kw.-hour consumption per ton-mile is lost by the low average efficiency of the generating plant.

In the above instances coasting was resorted to for a large percentage of the total running; if, however, coasting is not allowed, and the brakes are applied when the current is shut off, the two-motor equipment can complete the run in 21.82 minutes, or effect a saving of 5.75 per cent in time. The maximum output would be 2095 amps., and the average about 942, bringing the ratio of average to maximum up to 39.6 per cent.

If the four-motor equipment were used under similar conditions, the time would be 18.67 minutes, or about 20 per cent less than that taken by the two-motor equipment (coasting). The maximum output for this set of conditions would be 3407 amps., and the average about 1118, the ratio of average to maximum here being 32.8 per cent.

In practice the brakes would not be applied immediately the current was shut off, but to compensate for this, shunting the fields at starting and allowing a small amount of coasting for both equipments could be resorted to.

From the above considerations it would seem that to adopt very rapid acceleration at starting to reduce the energy consumed per "ton-mile" is uneconomical in working, and that the first cost of both generating and locomotive plant is about doubled. If, on the other hand, it is necessary to increase the average speed, a medium acceleration at starting will pay better than very rapid acceleration.

Entertainment at Berlin

The sixth annual oyster roast given by the Berlin Iron Bridge Company, of East Berlin, Conn., to its employees and a large number of invited guests was held April 26 at the factories of the company. Over a thousand of the company's friends partook of its hospitality, and the event was voted the most successful roast ever given.

Hundreds of barrels of oysters were provided, together with crackers, coffee, and other refreshments. The oysters were roasted in the forging shop and served at long tables. Dancing was enjoyed after the roast.

The Manufacture of Car Wheels*

BY G. R. HENDERSON

Like other branches of mechanical industry, the manufacture of chilled iron car wheels has been a gradually progressing science. Fifteen years ago it was customary to purchase and supply wheels to railroads on a mileage guarantee, the only restrictions as to quality being the depth of chill and the size, shape, and weight of the wheel. Certain mixtures were used by the founder which were known by experience to produce a given chill, and this and the color of the fracture, with perhaps the mileage records, were his guides in continuing his work. Chemical analyses of the pig iron and the finished output were considered unnecessary, if at all contemplated, and the irons, both coke and charcoal, were bought by fracture and chill. Some founders used a certain percentage of steel scrap, but this never became, as far as the writer knows, common practice. Now all this is changed; the progressive wheel-maker buys his irons on specifications, and checks them by chemical analysis, and every heat is tested physically and chemically. Records are kept of the strength and resilience of the various irons on the market, and of the manner in which his wheels fail, and as many as possible of these are examined in order to avoid duplicating unsatisfactory products.

The actual shape of the wheel has undergone but little change from the original Washburn section, except in the matter of size and weight, but we have every reason to believe that the older wheels cannot be compared with modern wheels in strength or endurance. A seeming inconsistency may be occasioned by a long life of old wheels, but it must be remembered that no such weight was then carried as is now the practice, where every effort is made in the interest of economical train movement.

About the time when the drop test was first introduced, the writer was assistant superintendent of a railroad shop which contained a foundry making 100 wheels per day. The introduction of this test, and the failure of a number of wheels in service about that time, caused him to make efforts to secure a stronger casting. Each day test bars were made along with the wheels, and these were subjected to transverse test, and a graphical record kept of the same, as shown by Fig. 1. The bars for this purpose were 2 ins. square by 24 ins. long, and were placed on supports 21 1/3 ins. apart, and a center load applied. As one-half the bars were chilled, it was considered that a 2-in. bar was a proper size to illustrate the chilling qualities, without becoming white through and through, and the span was fixed at 21 1/3 ins., so that when the proper deductions were made for the span and modulus of section, the corresponding direct stress was exactly four times the center load, thus facilitating the preparation of the form for recording the tests.

The bars of wheel iron so tested should stand a center load of from 12,000 to 14,000 lbs. before breaking, this corresponding to a maximum fibre strain of 48,000 to 56,000 lbs. per square inch. The deflection at the moment of breaking is also of great importance, and there are wide differences between various irons in this respect. While the *strength* of the metal indicates a power to stand pressure, we need the *resilience* to withstand shocks. A ready means of comparing the relative resilience of different irons is derived from the curve shown in Fig. 1. As the ordinates represent loads and the abscissæ deflections, the area bounded by the axis of abscissas, the ordinate passing through the final point of the curve (*i. e.*, the ordinate corresponding to the final deflection), and the curve itself will represent the work done or absorbed by the test bar up to the breaking point; and for quick comparisons the small rectangles into which the sheet is divided may be counted within the boundaries above mentioned. Good wheel iron will give curves with an included area of from 150 to 200 of the small rectangles, and a total deflection of 0.2 in. at center. Of course, these comparisons can only be made with bars of the same size and under the same conditions.

This same treatment has been accorded to unmixed pig iron of the various grades suitable for wheel founding, the pig being melted separately in a small experimental cupola, and from these records the wheel founder makes his selections. The curves present to the eye a meaning easier to grasp than mere figures, and when bound together in a book comparisons can be quickly and accurately made. The amount of chill and shrinkage are also noted, together with the color of fracture and the chemical analysis of the iron.

As the composition of different shipments of iron from the same furnace will vary greatly, it naturally follows that the strength and chilling properties are not always the same.

It happened not long ago that a certain iron, which had previously given good results, became almost unfit for use, princi-

* Paper read before the American Society of Mechanical Engineers, May, '99.

pally by reason of a great decrease in the amount of manganese. At one time this would probably not have been considered of such vital importance, but the fact has recently been well established that a certain amount of manganese is necessary in order that a wheel shall successfully stand the thermal test; it also seems to increase its strength under the drop test.

We have now seen that the wheel founder of the present day has the results of chemical analysis and physical tests of the unmixed iron, and also of the mixture, as well as the results of the drop and thermal tests, to guide him in his work. The tests of to-day's heat are carefully studied by him in order that any defects may be corrected to-morrow. For this reason it is important that the analysis and deflection test should be placed in his hands early.

The drop and thermal tests cannot be made until the wheels are taken out of the annealing pits, a period of from five to eight days.

But this is not all. These tests are intended to show us quickly what kind of service we may expect from our wheels when under the cars, and the records of the life and failure of wheels in service are of the utmost importance. The actual mileage of a wheel under a freight car is a difficult thing to obtain; that is, it requires considerable labor, especially when the number of wheels in use runs up into the hundred thousands. For this reason the life of wheels is often kept by months; and while this does not take into consideration the time spent in the repair yard or on the side track, it has the advantage of being very easily obtained.

As new wheels are made, the foreman of the foundry makes a daily report, giving the wheel numbers and the mixture used. The former are entered in a book which contains the serial wheel numbers, and the latter are entered in another book, which later has the result of the drop and thermal tests recorded, as well as the depth of chill, shrinkage, etc. When the wheels are mounted on the axles, a report is made weekly of the number and place at which this work was done, and this is entered in the book with serial numbers. Each week a report is also made from each point at which wheels are scrapped, giving the number and the cause; and when these are also entered, we have a complete record of dates and places of the "birth, marriage and death" of each wheel.

In looking over such a record it is at once apparent that a large number of wheels are always damaged by improper handling or usage. The proportion of *slid-flat* wheels has been very large heretofore; we hope that the more general use of air brakes will effect an improvement in this line. Chipped flanges and worn flanges are also not generally chargeable to the wheels themselves.

What most interest the founder are those which are scrapped for *cracked plates*, *cracked brackets*, and *broken-to-pieces*, as these show improper manufacture in the majority of cases. As the master car builders' regular guarantee is for forty-eight months, all wheels which run over five years may be considered as giving good service; and if these wheels can be obtained, the study of their analysis is very beneficial. Therefore, wheels giving a very short service or a very long one should be carefully inspected and analyzed, as they will show the bad and good features in a much more forcible way than drop or thermal tests. Mr. W. W. Davis, chemist of the Norfolk & Western Railway, who, with the writer, has given much attention to this subject, analyzed a large number of wheels giving a long or short service or tested by the drop or thermal methods, and we present the results of some of his work:

	Analysis of Car Wheels.					
	Which Stood Thermal Test for 60 Mins.		Which Stood 40 or More Blows Drop Test.		Which Gave 5 or More Years of Service.	
	Max.	Min.	Max.	Min.	Max.	Min.
Graphite	3.28	2.65	3.31	2.65	3.18	2.23
Combined carbon	.95	.32	.90	.55	1.24	.56
Silicon	.75	.50	.70	.50	.94	.58
Manganese	.53	.20	.46	.24	.34	.13
Sulphur	.088	.055	.086	.040	.085	.047
Phosphorus	.48	.35	.52	.36	.49	.25

It will be seen that these limits are rather wide, but below are given what are considered to be the desirable limits for the chemical constituents of wheels:

Desirable Wheel Analysis.				
Graphite	2.75	per cent. to	3.00	per cent.
Combined carbon	.50	" "	.75	"
Silicon	.50	" "	.70	"
Manganese	.30	" "	.50	"
Sulphur	.05	" "	.07	"
Phosphorus	.35	" "	.45	"

By comparing the above with the analyses of a large number of wheels it was found that these limits excluded those which broke through rim in ten minutes or less under the thermal test; broke with twenty blows or less under the drop test; or gave less than two years' service. This last is important, as a wheel can easily be made to stand strains, but the wear will be unsatisfactory, and the metal must have enough chill to stand the abrasion of the track. It is possible to obtain a chill ¾ in. deep on the tread with these proportions.

The analyses of seven wheels which had given from eight to eleven years' service each had the following limits:

Graphite	2.56	per cent. to	3.10	per cent.
Combined carbon	.63	" "	1.01	"
Silicon	.58	" "	.68	"
Manganese	.15	" "	.27	"
Sulphur	.05	" "	.08	"
Phosphorus	.25	" "	.45	"

Fig. 2 shows the comparison between chemical analyses of pig iron and of the test bar made by remelting the pig in a cupola by itself. Twenty-seven different irons were examined in this way. The solid line represents the analysis of the pig, and the broken line that of the test bar. It will be seen that phosphorus remains constant, as does silicon when present in quantities under 1 per cent, whereas some of the manganese always disappears. The total carbon remains the same, but the proportions of graphitic and combined carbon seem to vary in an erratic manner. This is evidently due to the effect of the chill, as the analyses were made from the chilled test bars when possible, and the great increase in combined carbon in tests Nos. 11, 12 and 22 may be accounted for by the fact that they chilled clear through the two inches.

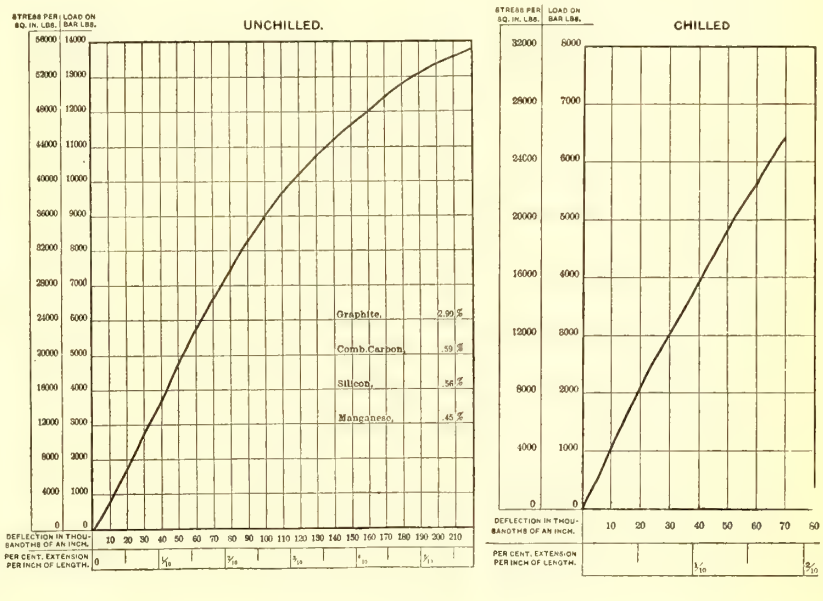

FIG. 1

From the above it will appear that the metal charged into the cupola should contain more graphite, silicon and manganese, and less combined carbon than are desired in the finished product.

If the iron in stock is deficient in manganese, the proper amount can easily be added to the mixture in the ladle by the use of ferro-manganese containing about 80 per cent manganese, 13 per cent iron, and 6 per cent carbon (combined). The use of large proportions of scrap makes this particularly useful, and it is of great assistance in enabling the wheel to stand the thermal test, and consequently the strains from severe braking when in service.

Indeed, cracked plates are almost a thing of the past with foundries keeping the manganese up to the limits prescribed above, where previously much trouble was due to that cause. To overcome this it appears that ¼ of 1 per cent should be present in the wheel. Ferro-manganese, however, seems to reduce the chill by increasing the graphitic carbon, as Fig. 3 will show, and this must be allowed for in proportioning the charge for the cupola. The combined carbon is partly changed to graphite, but not entirely in proportion to the amount of ferro-manganese used.

The experiments from which results Fig. 3 was constructed were made by filling small ladles containing different proportions of ferro-manganese from a large ladle which had been filled with the regular wheel mixture, and casting test bars from these small ladles. The effect of this is plainly illustrated both in altering the structure of the iron and the condition of the carbon content.

In preparing specifications for charcoal irons the difficulty of obtaining limits which should be perfectly satisfactory was not

underestimated. It is therefore hoped that these will be criticized more as representing an effort to compass a complicated subject than as an absolute specification which has stood the test of time.

CHARCOAL PIG IRON

"The material desired under this specification is a charcoal iron with chilling properties as designated below, the various grades to conform to the detail specifications:

Grade.	Chill.	G. C.	C. C.	Si.	Mn.	S.	P.
2	¼ inch.	2.50–3.00	.40–.90	1.25–1.75	.50–1.00	.03 Max.	.25–.40
3	½ "	2.25–2.75	.50–1.00	1.00–1.50	.50–1.00	.03 "	.25–.40
4	¾ "	2.00–2.50	.75–1.25	.75–1.25	.50–1.00	.035 "	.25–.40
5	1 "	1.75–2.25	.90–1.40	.50–1.00	.25–.75	.035 "	.25–.40

"The chill is to be measured in a test bar 2 ins. square by 24 ins. long, the chill piece to be so placed as to form part of one side of the mould. The actual depth of white iron will be measured. The white and gray portions should blend without a definite line of demarcation. The test bars will be made by melting in a small cupola several pigs of the shipment without admixture with other irons.

"The chemical proportions given above are the amounts of the constituents desired in per cents, and will be determined by the analysis of mixed borings in equal quantities taken from twelve pigs from each car.

"In addition to the chilled test bars above mentioned, some unchilled bars of the same size will also be made. These will be placed upon supports 21 1/3 ins. apart. A center load will be applied and the deflection measured. The bar should not break with less than 9000 lbs., and the deflection at center with this load should not be less than 0.15 in."

While charcoal iron is the principal ingredient in car wheels, it is often advantageous to use a small amount of coke iron, and the following specification is therefore submitted:

COKE PIG IRON

"The material desired under this specification is an open-grain foundry pig conforming to and graded by the following detail specifications:

Grade No. 1, Silicon, from 3.00 per cent. to 2.50 per cent.
" " 2, " " 2.50 " " 2.00 "
" " 3, " " 2.00 " " 1.50 "
" " 4, " " 1.50 " " 1.00 "

"Iron will be rejected which shows:

Combined carbon below	.10 per cent.	
Graphitic carbon below	3.00 "	
Manganese below	.50 per cent.	or above .80 per cent.
Phosphorus below	.50 "	" .80 "
Sulphur above	.06 "	

"Should the silicon vary from standard grading, the next lowest grade under the specifications will be paid for, and should the silicon fall two grades low the material will be rejected. No higher grade is desired, and no excess price will be paid for higher silicon.

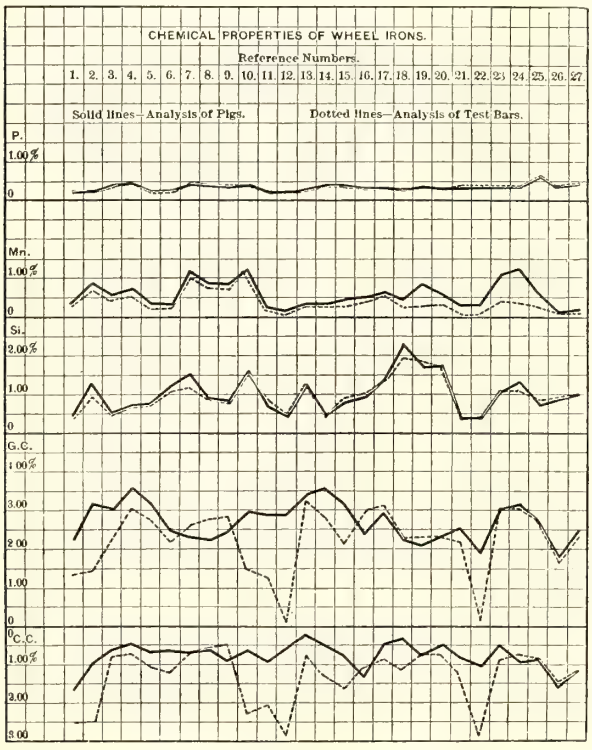

FIG. 2

"Samples of twelve pigs will be taken from each car, two from the top of each end, two from the middle, and two from the bottom. The borings will be mixed in equal quantities and the resultant sample represent the shipment."

Reference having been made to the drop and thermal tests, it may be well to conclude this paper with a specification for car wheels, which will give the details of these tests for ready reference.

33-IN. CAST IRON WHEELS

"The design of wheels must be such that they will be in accordance with the measurements shown on the drawings for 33-in. wheels, and also such that the wheels when cast shall weigh between 590 and 610 lbs. The tread and flange are to be identical with the M. C. B. standard section for same, and the flange thickness must pass the M. C. B. gages for same.

"Wheels must all be cast in true metallic chills of the same internal diameter and of uniform cross section. The body of wheel must be of clean, soft, gray iron and smooth and free from slag and blowholes, and hubs must be solid and free from drawing. The tread and throat of wheel must be smooth, free from deep and irregular wrinkles, slag and sand-wash, and practically free from chill cracks and sweat. The depth of clear white iron must not exceed ⅞ in. at throat and 1 in. at middle of tread, nor be less than ⅜ in. at throat and ½ in. at middle of tread. Neither should there be a variation throughout the same wheel of more than ¼ in. in depth of chill. The blending of the white iron with the gray iron behind it must be without any distinct line of demarcation.

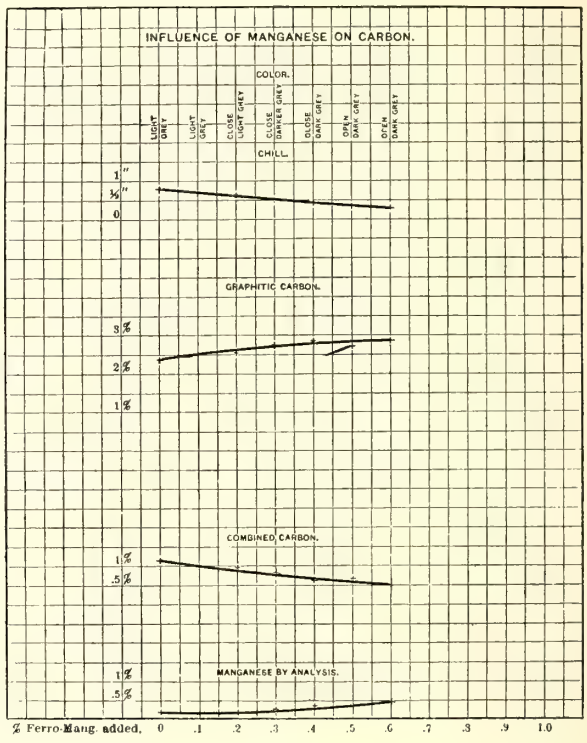

FIG. 3

"Each wheel must be so nearly circular that when a true metallic ring is placed upon the tread, and bears somewhere on the cone, it shall at no part of the circumference stand more than 1/16 in. from the wheel tread. No wheel made in a solid chill will be accepted whose circumference differs more than 1⅝ ins. or less than ⅞ in. from the circumference of the chill in which it is made. Wheels cast in contracting chills should not differ in circumference more than 2 ins. from that of the chill.

"All wheels must, during inspection, receive three heavy blows with a 6-lb. sledge at as many different points under the flange, between the brackets, without cracking flange or brackets.

"Each wheel must also be capable of standing a pressure of 50 tons when being mounted on the axle.

"For each pouring of 100 wheels, or fraction thereof, two additional wheels must be furnished for test purposes. These wheels shall be selected by the inspector, and subjected to the following test: One wheel shall be placed flange downward on an anvil block weighing not less than 1700 lbs., set on rubble masonry 2 ft. deep, and having three supports not more than 5 ins. wide for the flange of the wheel to rest upon; it shall be struck centrally upon the hub by a weight of 140 lbs. falling from a height of 12 ft. Should this wheel stand fifteen blows without breaking in

two or more pieces, the lot of 100 may be accepted (as far as this test is concerned), provided that the broken wheel shows proper depth and uniformity of chill; also subject to return if the wheels do not satisfactorily stand boring and mounting, as explained above. Should the wheel break in two or more pieces with fifteen or less blows, the lot of wheels represented by the one tested will be rejected.

"The other test wheel must be laid flange down in the sand, and a channelway, 1½ ins. wide and 4 ins. deep, must be moulded with green sand around the wheel. The clean tread of the wheel must form one side of this channelway, and the clean flange must form as much of the bottom as its width will cover. The channelway must then be filled to the top with molten cast iron, which must be hot enough when poured so that the ring which is formed when the metal is cold shall be solid or free from wrinkles or layers. The time when pouring ceases must be noted, and two minutes later an examination of the wheel must be made.

"If the wheel is found broken in pieces, or if any crack in the plate extends through the tread, the 100 wheels represented by the test will be rejected.

"Wheels may be dried before submitting them to the thermal test, but must not be warmer than 100 degs. F."

Street Railway Franchises and Fares*

BY EDWIN B. GAGER

So many bills are now pending before you relating to street railways and depending for their intelligent consideration upon a knowledge of the financial condition of the street railway interest in Connecticut, that I have been at the pains of collecting some facts which seem to me pertinent. The transfer bill (H. B. 360), the electric lighting bills (H. B. 371 and H. B. 499), the bill concerning street railway franchises (H. B. 502) and the various fare bills and resolutions (H. J. R. 373, H. B. 497, H. B. 219, H. B. 19, H. J. R. 372) are the more important examples of the class of bills I refer to. You cannot fail to have noticed that in every case these bills have been advocated because it was claimed that the street railways had been granted valuable franchises, that they used the highways for nothing, and that the additional burdens sought to be imposed by these bills could well be borne by the companies as some compensation for these so-called valuable franchises.

Many supporters of these bills, especially the fare bills, have gone so far as to claim that these burdens should be imposed because the people would receive a benefit which they should have whether the companies could afford it or not. Others claimed the companies could afford it. Not a single claim in support of these bills, nor a single argument has been based upon an examination of the conditions and facts fundamental to the proper discussion of these questions. The popular notion of this "valuable franchise" is made to do duty in support of any and every measure imposing further financial obligations upon these companies.

What is this "valuable franchise"?

It is not the right to be a corporation. That right, which is a franchise, is common to all corporations whether created under the general law or by special act of the Legislature. The franchise intended is the right, obtained from the Legislature, to lay down and operate a street railway in the streets and highways without paying for such a right by way of purchase. It is claimed to be a free right of way through our streets, of great pecuniary value, given without compensation to the State or the municipality.

Let us examine the nature of this right. It is a right to operate our vehicles, or cars, in the streets. These cars are the cheapest and most comfortable means of local travel yet devised, which, for most distances, you can hire for your personal use for five cents. This right, therefore, is really a right which enables the people to travel frequently, speedily, comfortably and cheaply. The only thing about it rendering a franchise necessary is that in order to furnish such a service these vehicles must run over a prepared surface or track. In no other respect does the street car differ from the ordinary bus. Any man may establish a line of busses without a franchise and without compensation for the use of the streets. No one would think of imposing special burdens on him. Yet he does not take care of a strip of road nearly 9 ft. wide for a single track at his own expense and pay taxes besides, and then furnish the cheapest service in the world. The Massachusetts Railway Commissioners in their report for 1896 (p. 111) said: "The railway is not to be regarded as an intruder, having no legitimate place or right to be on the public street. It is nothing more or less than an improved method of public highway travel. The use of the highway by one method of travel necessarily interferes to a greater or less extent with the convenience and safety of its use by other methods. There are well known inconveniences and dangers to other travelers attending the use of the highway by travelers in street cars. It must be conceded, however, that there is no known method of conveyance by which such large numbers of persons can be transported through the streets with so much convenience, expedition, and safety to themselves and other travelers, with so litttle noise, confusion and dirt, and with so little obstruction and wear and tear of the street, as by the electric railway. There are carried on the railway whose lines center in Boston, an average of 425,292 persons daily—a number equal to nearly 86 per cent of the entire population of the city. The great majority are carried through the most crowded thoroughfares. If it were possible to transport the same number of persons by any other available method of public or private conveyance, the obstruction, annoyance and danger would, on the whole, be much greater than they now are."

Our every day experience justifies every word of this statement.

But it is said that this right is of immense financial value to these companies. We admit that without this right we could not do business. We deny that, in Connecticut, this right has an appreciable financial value as an asset of the company, adding substantially to the market value of the company's property.

A franchise, to have a financial value as such, must be of such a nature that it will enable its owner to reap a financial profit from its possession in excess of a reasonable profit on his property investment. For illustration, a patent right is a franchise. That right or franchise is of value when it enables its owner to gain a profit or reward beyond the normal return on the capital invested. If a patented article sells for two dollars where, if open to general manufacture, it could be sold at one dollar, and at the same time secure the normal return on the capital invested in its manufacture, then this extra dollar represents the value of the franchise secured by the patent. If a street railway company can, by the use of its franchise to run in the highways, secure a return far in excess of the normal return required by its investment and the risks of its business, so that its property is worth largely in excess of what has been put into it, such excess would represent the value, the financial value, as an asset, of its franchise.

No such value exists in this State, and this is so for several reasons:

1. There is nowhere in this State sufficient density of population. There is no travel to be accommodated that is far in excess of and above the proportion required by the outlay necessitated to construct, maintain and operate the line. You cannot reason from New York and Chicago to New Haven and Hartford, much less to the other cities and towns in this State having street railways. In short, we have not the people to be carried proportional to the miles of track, required to create a financially valuable franchise.

2. This franchise right has not the element of permanency, if the other conditions existed, to make it materially valuable. Every charter in the State is subject to alteration or repeal at the pleasure of the General Assembly. New lines may, at any session of the Legislature, be authorized on streets already occupied or on parallel streets. There is no monopoly in this respect that cannot be broken the moment the Legislature deems the interests of the traveling public require it. A right uncertain as this does not furnish a sound basis for a financial value.

3. If, at any time, it appears to the Legislature that any such franchise is enabling its owner to reap an inordinate profit, the Legislature by its reserved powers has the right to compel a reduction of charges so that the returns will not be out of proportion to the capital invested and the nature and risks of the business.

For these and, perhaps, other reasons, we say that the franchise of a street railway in this State is not, of itself, of substantial financial value. It is simply a preliminary right required to do business, just as the right to use the highways is a preliminary right requisite to enable a man to engage in trucking or running a bus line, and nothing else, and through the medium of the Legislature is subject, like any other business, to the law of competition.

Now if there is, as is claimed, a financial value to this franchise, it ought to appear in the financial results of construction and operation of electric lines in this State.

Two years ago, I had occasion, before the judiciary committee, to examine this question. I could not then find this value. I have re-examined the question and beg leave to submit the results of my examination. It is based on the reports for 1897, the last reports for a full year, and for 1898 so far as available. Briefly stated, the proposition is this: If a street railroad franchise is a

* Address delivered before the committee on railroads of the Connecticut Legislature, May 3, 1899.

valuable pecuniary asset it ought to appear as a material element of value beyond the capital invested in the roads. Such an element I do not find. Several tests may be made.

Take the test of taxable value. Street railways are required to pay to the State 1 per cent on the fair market value of stock, bonds and other indebtedness, just the same as steam roads. The board of equalization has full power to determine this value, and no one but a crank will question that this board has treated the State fairly. In this particular we can use the reports for 1898.

In 1898 the street railways of the State paid to the State Treasurer in taxes $161,164.36. This is 1 per cent on the value of these properties as determined by the board and makes the fair market value of all street railway properties in the State $16,116,436. By the same report the actual cost of construction and equipment was returned as $19,806,240.78. In other words, the fair market value was $3,689,804.78 less than the cost of construction and equipment. There is no margin here for this "valuable franchise." But was this fair market value really fair? For the answer to this we must go to the reports of 1897, as those of 1898 are as to business done, for only nine months. The net earnings of all the roads for 1897 were $951,412.30. From this sum was paid in taxes $132,937.47, leaving for depreciation, interest and dividends $818,474.83. The market value for that year was placed at $13,293,747. This makes the net earnings for that year, exclusive of taxes, 6 1-10 per cent, out of which must come the element of general depreciation of plant which the companies generally have not, in my judgment, sufficiently allowed for. No one at all familiar with the nature of the business and the element of depreciation will say that the valuation was over favorable to the roads.

If we take now the cost of construction and equipment for this same year, viz: $19,849,206.52, then the net earnings, exclusive of taxes, will be 4 1-10 per cent. This does not disclose the "valuable franchise." In Massachusetts in 1897 the net earnings were 6 4-10 per cent on the cost of construction and equipment (Report of Mass. Special Commission. House . . . 475, p. 37).

The stock, bonds and floating indebtedness for the same year amounted to $19,934,661.25, substantially the same as the construction and equipment account and showing substantially the same return, 4 1-10 per cent.

The capital stock of these roads amounted to $9,770,440, and the dividends paid amounted to $265,625.97, being 2 7-10 per cent on the capital stock. The "valuable franchise" element does not appear here.

The steam roads, as a whole, showed in 1897 net earnings, less taxes, of 6 per cent on stock, bonds and floating debt and 7 1-10 per cent on cost of construction and equipment as against 4 1-10 per cent in each case, respectively, for the street railways.

That the reports as to cost of construction and equipment are substantially correct, will appear from a comparison with the reports as to street railways in Massachusetts. In 1897 the average cost per mile of all the street railways of Massachusetts was returned as $44,415. This included long country lines, comparatively inexpensive, for there were in Massachusetts 1413 miles of main track as against 362 in Connecticut, and many of the Massachusetts companies had charged off for depreciation. In 1894 the average cost per mile in Massachusetts was $53,632. (See Table R. R. Comrs. Report for Mass., 1898, pp. 89 and 106). Our average cost per mile was reported in 1897 at $54,829, and in 1898 at $51,177.

This is somewhat in excess of the actual railroad cost, for the commissioners say (Conn. R. R. Comrs. Rep., 1898, p. 27) "the cost of construction and equipment include the cost of electric lighting plants in several companies which cannot be separated from the cost of road and equipment."

You are asked on most of these matters to legislate for the whole State on the theory of this valuable franchise, the use of the street, which it is claimed the roads can afford to pay for indirectly in the various ways presented in these bills. The ultimate reason alleged does not exist. There is no such valuable franchise to draw upon.

As confirming my results reached from an examination of our reports, I would refer to the report of the exceptionally able special commission appointed in 1897 to examine and report on the question of street railways The committee consisted of Charles Francis Adams, William W. Crapo and Elihu B. Hayes. They examined with the greatest care the street railway systems of the United States, Great Britain and the Continent and their report is of very great interest and value. If our friends would study it carefully, they would not be making some of the absurd claims you have heard. On this subject of valuable franchise permit me to quote the following: "So far, however, as a further special street railway franchise tax is concerned, grave popular misapprehension seems to exist as to the burdens in the way of taxation to which street railway companies are already subject—a misapprehension due in no inconsiderable degree to the indirect and anomalous character of those burdens. It seems to be generally assumed that the street railway companies received, and are now receiving, public franchises of unusual value, for which they pay no money consideration and render very inadequate public service; that their profits consequently are inordinately large is also assumed, and that those profits are in some way concealed through a system of vicious financiering and deceptive bookkeeping.

The facts, however, do not seem to be as assumed in this presentation of the case. A more careful investigation fails to disclose those Massachusetts franchises of great value given away without consideration, or unduly large profits on the part of the companies as a whole, or more than exceptional cases of vicious financiering, or a deceptive general system of bookkeeping. There are in all seventy-seven street railway companies in operation in the Commonwealth. Of these, one, the Boston Elevated, or West End Street Railway, may be left out of consideration, its case being exceptional to such a degree as to make it necessary to put it in a separate class, as has, in fact, been done through recent legislation (Acts 1897, chapter 500). Of the seventy-six remaining active companies, thirty-four paid no dividends in 1897, while forty-two paid dividends of from 1.25 per cent to 10.5 per cent, averaging 4.29 per cent—a return certainly not excessive. Upon this point the inquiries of the committee tend to confirm the conclusions of the Board of Railroad Commissioners in their report for 1896 (page 110). While in the business of operating street railways, as in every other business, there are—as, within reasonable limits, there should be—exceptional cases of large profit offsetting cases of failure to earn reasonable profits, yet the idea sometimes entertained that the electric railway is likely to prove a source of extraordinary or abnormal profit must apparently be abandoned. It is a close business, yielding with skilful and prudent management only a fair average return, quite within the limit allowed by statute and conservative opinion as adequate and proper for investment of this character. (Report of Special Commission, pp. 35, 36).

I doubt not you have been struck by the difference between estimates for new lines and the reported cost per mile which I have stated. This is accounted for when you recollect that the value of the older horse railroad plants and the heavy cost of material and plant in the earlier days of electric road construction have to be taken in to the equation.

All this represents actual cost which has gone into the plant and on which the companies are entitled to receive a reasonable return. This feature is so concisely and fully covered by the report of the Massachusetts Commissioners (Report, 1898, p. 110), that I reproduce it in full:

"The establishment and maintenance of an electric railway is a very different thing in point of cost and expense from that of the horse railway. There has been, moreover, a certain amount of loss in the reconstruction of the horse into the electric railway. The construction and equipment accounts of the older companies represent to some extent the cost of two systems, only one of which now exists. There has been besides a very considerable shrinkage in the value of the electric railway properties which were built or reconstructed some years ago, owing to the large reduction in price or market value of material. The motors which cost $2850 can now be bought for $850. A suburban railway which it cost $35,500 per mile of track to build and equip, including power plant, in 1892, could be built and equipped in the same manner the last spring, for $22,600 per mile. Many of the companies require, in order to place or maintain themselves on a sound financial basis, to charge off from their property accounts large sums for shrinkage and depreciation of this character, if of no other character, as soon and as fast as their surplus earnings will permit."

The promoters of these bills desire to take away, as far as possible, all chance for any surplus earnings which will enable the older companies to charge off that portion of their investment which has become valueless so far as the present operation of their roads is concerned. This policy would be extremely unwise for a manufacturing company, and it is equally so for a street railway company.

There is another element in this question which is not to be overlooked. It is said prices generally have gone down, and that we are now paying five cents for a ride that in horse railroad days cost at the most but six. In the "Street Railway Review" of Feb. 15, 1897, is a carefully prepared article on " Reduction in Street Car Fares."

From an examination of twenty-eight large and small cities the writer came to the conclusion "that the price of car fares not only has been reduced, but that no other article of as common use has been as greatly reduced in price."

This reduction has been brought about in three ways, by making a straight five-cent fare, by great extensions of lines and by transfers. The whole matter is exhaustively examined and taking the years 1886 and 1896 for comparison, and taking the purchasing power of five cents in 1886 as the unit, it was found that five cents would in 1896 buy a ride 3.375 times as long, while of steel rails it would buy 1.74 times as much, of sugar 1.37 times as much, of wheat 1.34 times as much and of cotton 1.22 times as much. And this takes no account of the increased speed and comfort of the traveler.

The result in Connecticut is substantially the same. In Bridgeport in 1885 you could ride 4 miles for five cents. Now you can ride 9.75 miles. In 1885 the Fair Haven and Westville R. R. carried a passenger at the lowest rate, 3½ miles for five cents. Now you can ride 9½ miles for the same rate. In Waterbury in 1886 you could ride 1½ miles for five cents. Now you can ride 6½ miles for the same sum. In Hartford in 1892 you could ride 2.9 miles for five cents. Now you can ride 9.18 miles for the same sum.

This very important element should not be lost sight of, that the quantity of service has been tripled while its quality has been greatly improved.

Comparing this with the steam road rates, it will be recollected that on steam roads rates to-day are substantially the same as in 1885, the standard being now, as then, two cents per mile.

But it may be said, and especially in relation to the fare bills, that in New Haven, Hartford and Bridgeport, neither your figures nor your reasoning will apply. From their size we ought to, as we do, find the best results in these cities. These results, however, do not come up to the results on the consolidated road, and this Legislature has already refused to attack its fares. We do not expect different treatment from the steam roads unless it appears we are doing much better than the steam roads. I have already shown that the general result on street roads is 4 1-10 per cent, as against 6 per cent on stock, bonds and debt of steam roads, and 4 1-10 per cent as against 7 1-10 per cent on cost of construction.

The Hartford Street Railway Company controls the entire traffic of the second city of the State. The total cost of its construction and equipment was reported in 1897 as $2,608,030.43. Its net earnings, less taxes, $155,212.15, or 5 9-10 per cent on its cost of construction and equipment. Its capital stock, bonds and debt amounted to $2,469,000, upon which its net earnings would be 6 3-10 per cent. This is less than the general average of the State on steam roads, based on cost of construction, and only 3-10 of 1 per cent above on stock, bonds and debt. There is no franchise value here.

In New Haven the traffic is divided between two companies, the Fair Haven & Westville and the Winchester Avenue lines, which in a general way divide the city, the Fair Haven and Westville having taken in the New Haven Street Railway Company. The total cost of construction and equipment returned in 1897 was $3,615,924. The net earnings, less taxes, $264,638.27, or 7 3-10 per cent of cost of construction and equipment. The total capital stock, bonds and debt of the New Haven roads was $3,026,700, upon which its net earnings would be 8 7-10 per cent. This is a little better than the average steam road results. This, however, is far below the results upon the consolidated road, which for the same period showed 15 per cent on cost of construction and equipment and 9 + per cent on its total investment, and paid 8 per cent dividend with a surplus of $74,728.76.

The Bridgeport Traction Company reports a cost of construction of $3,836,468, and net earnings of $123,145, or 3 2-10 per cent on cost. Its stock, bonds and debt were $4,030,000, upon which its net earnings, less taxes, were 3 + per cent. Now, none of these roads so far as appears charged off for general depreciation. It is self-evident that no ordinary repairs will quite suffice to keep a road up to its best standard, that there must at times be reconstruction as distinguished from repairs. This will not come till a road has been some years, perhaps ten or more in operation, but it is sure to come and must be met by an extraordinary outlay which must increase the permanent investment unless provision is made for this expense either by charging off some percentage yearly or the creation of a surplus. For the long continued operation of a road the above percentages should be materially reduced to show a sound basis of net income which can be paid to the stockholders as dividends.

The foregoing figures do not show a situation which justifies the Legislature in interfering in the business management of these companies. They are simply well managed, fairly successful companies, such as we would like to see all the railway companies in the State.

The more we study the reports and the more we learn about the narrow margin of profit after paying all expenses of operation, maintenance of track and roadway and taxes, the less shall we feel inclined to look at street railways as furnishing any short and easy road to wealth. The cold fact is, taking them generally, that thus far the riding public and the local property owners have been the gainers. Stockholders have invested on faith in ultimate results which have not yet been realized. The best of the roads have done no better than a fairly successful manufacturing or mercantile business. If they are left to themselves to conduct their business on ordinary business principles without spasmodic, uncertain and almost surely disastrous legislative interference, the public will be better served and the just claims of those who have invested their money better protected.

Permit me to quote again from the Massachusetts Report already referred to (p. 110). I do this the more freely because in Massachusetts the street railways have long been under supervision of an able board and the conclusions reached by it are based on a wider experience than has been possible in our State:

"It is not by any means intended to convey the impression that electric railway operation is, or is destined to be, a financial failure. The idea that it is likely to prove a source of extraordinary or abnormal profit must, however, be abandoned. It is a close business, yielding with skilful and prudent management only a fair average return, quite within the limit allowed by statute and conservative opinion as adequate and proper for investments of this character. It was suggested in the report of two years ago that the financial conditions and results of street railway enterprise would not be found to differ in the long run essentially from those of railroad enterprise. The average return on street railway capital was the last year a little below that on railroad capital, in this State."

This conclusion, you will observe, coincides absolutely with the conclusion reached from an examination of our own roads and is not, I think open to question. If this conclusion is correct, then every proposed law based on the idea of valuable franchises and excessive profits and which must result in directly or indirectly diminishing these profits must be rejected, because the assumed conditions do not, in fact exist.

It has been said by those who are favoring these various bills, and especially the fare bills, that foreign cities furnish very much more favorable rates than are furnished with us. Upon this point I beg again to refer to the report of the Massachusetts Special Committee already mentioned. This committee was not unmindful of the claims of the visionary and enthusiast, that somewhere beyond the seas, a condition existed that was infinitely better than our own, and they examined the roads of Great Britain and the Continent, and as a result of a careful examination, have said this: (See Report, page 15): "On this head, as already intimated, it is not safe to accept loose assertions, no matter how positively made or frequently reiterated, as evidence of what really exists. In every community, persons claiming to speak as authorities are apt to be in evidence declaring that somewhere else, in this case in Baltimore, perhaps, or in Toronto, in Glasgow, or in Birmingham, or in Berlin, an ideal condition of affairs has been reached, in which perfect street railway accommodations, low fares, rapid transit, and contented officials and employees are working in harmony with a thoroughly well-satisfied municipal government, to the expenses of which the railway company contributes a liberal share, while at the same time paying reasonable dividends to its stockholders. The members of the committee have only to say that, if such a street railway Utopia anywhere exists, they have in the course of their investigations failed to find it."

Various foreign cities have been mentioned in which the street railway management would, it is claimed, throw the excellency of our American systems into the shade. Among others those of Birmingham, Glasgow and Berlin. I can only refer in detail to one of them, and I take my figures from the same special report, pages 16, 214 and 217. Glasgow has a population of some eight hundred thousand, served by 73 miles of tramway measured as a single track. Compare this for a moment with Hartford with a population recently estimated at about 75,000, and served by 56 miles of track; or New Haven with a population in the neighborhood of 100,000, served by between 70 miles and 75 miles of track; substantially more miles of track in New Haven than in Glasgow. In Great Britain at least the same ratio will very generally apply. For instance, Birmingham with a population of 501,000, has 33 miles of track; Southampton with a population substantially that of New Haven, has 5 miles of track; or, taking the United Kingdom generally, Great Britain shows 618 miles of street railway in a city population of 7,600,000, while Connecticut, with its little population of 800,000 urban and country, has 387 miles. But even with the very short mileage of tracks in Great Britain and upon the Continent, there is to be specially noted the fact that rates there are based upon distance instead of the flat five-cent rates for ordinary service as with us, and the distances are divided so that they

increase by comparatively short stages. Take Glasgow again for illustration, we find there that on the rate of the Glasgow corporation, for one cent you can ride one-half of a mile; for two cents, 1¾ miles; for three cents, 2 1-3 miles; for four cents, 3½ miles; for five cents, 4 2-10 miles. You cannot, in Glasgow, in our money, buy as long a ride for five cents as you can upon most of the street railways in Connecticut.

It has been said over and over again that the street railway is the poor man's carriage; practically, we know, it is the carriage of the rich and poor alike. But look at it from the point of view of a man working for wages. In Glasgow it costs him a much greater proportion of his wages to travel a given distance than it does with us. For illustration, in Glasgow point boys, as they are there called, or switch boys, as we would call them, get 28 cents a day; in New York the boys doing the same service get $1 to $1.25 per day. Drivers and conductors, as their highest rate of wages, after three years' service, get $1.08 a day, as against $2.25 in New York for conductors and $2.40 for motormen; and so it runs through the various classes of workingmen upon the roads, and this relative scale of wages is, I believe, about proportional to the difference in wages between Glasgow and this country, so that actually a man who is working in a shop or anywhere for wages here has to work less time to get a given mileage of ride than in Glasgow.

Well might the Massachusetts committee say that, after examining these conditions in the Old World, they have failed to find the street railway Utopia which the visionaries loudly, and with amazing assurance, claim existed there.

There is another point of view founded on the foregoing examination. We have seen that the average street railway net earnings, without deducting for general depreciation, is 4 1-10 per cent on cost of construction and equipment, and 4 1-10 per cent on total stock, bonds and floating indebtedness, yielding after paying interest charges 2 7-10 per cent on capital stock, and that under the very best conditions in the State, viz., New Haven; still without deducting for general depreciation, the net earnings show only 7 3-10 per cent on cost of construction and equipment, and 8 7-10 per cent on capital stock, bonds and floating indebtedness. Now, as a fair business proposition, at what point can the Legislature presume to manage or regulate the financial management of these roads better than those who make it their business to manage street roads? Do you think, as careful business men, that an average of 4 1-10 per cent will, with any information you have obtained here, justify you in imposing additional burdens on all the roads of the State, or that the exceptional rate of 7 3-10 per cent, under the most favorable conditions, will justify you in interfering in the management of the roads in the larger cities?

Do you think so, especially in view of the fact that in the case of a steam road earning 15 per cent on cost of construction and equipment you have, properly enough, deemed it unwise to interfere with its rates?

What is the point where the Legislature may, with propriety, be asked to consider the rate question? Perhaps the neighboring States may aid in answering, for I assume that this committee is desirous of dealing with all these bills in a prudent, conservative way.

In New York it is provided that rates may be reduced, but not below a net income of 10 per cent on the amount actually expended. In New Hampshire rates may be regulated, but not so as to reduce the net income below 10 per cent on the capital stock. In Massachusetts the Railroad Commissioners control the rates, but no reduction is permitted which will bring the income below 10 per cent on the actual cost. We have no law, but rely upon the good sense of the Legislature, and primarily of this committee, and I submit that you can justify yourself to the business world if you conform to the standard of New York, Massachusetts and New Hampshire. The street railways generally, and every one of them in detail, do not show, nor can they be made to show, any such net income as will justify your interference in the management of their financial affairs.

No one can be presumed to know better than the managers themselves what the financial results of any change in rates would be. If advantageous to the companies, they would long ago have been adopted. If disadvantageous, then you certainly will let them alone. The settled policy of this State has been hands off. The result has been that our railroads and street railways have been as well managed, and the public have got as good service at as low rates as in any State of the Union.

The Legislature of the State of Wisconsin has just enacted an anti- pass law, by virtue of which no city, county or State official or employee will be permitted to accept or use passes of any kind on steam or street railways. This law applies as well to local police.

Receipts of Street Railways in New York State

At the hearing on the Ford Franchise Tax bill, before Governor Roosevelt, Executive Chamber, Albany, N. Y., May 11, 1899, the following statement was submitted by G. T. Rogers, president of the Street Railway Association of the State of New York.

STATEMENT

The following facts and figures are compiled from the annual report of the State Board of Railroad Commissioners for 1898:

One hundred and three street surface railroads submitted annual reports to the State, forty-nine of which show a surplus amounting to $1,102,855, and fifty-four show a deficit amounting to $471,848. Of the $1,102,855 surplus, $805,288 is shown by twelve companies in Greater New York, leaving but $297,567 to be divided among the thirty-seven companies outside of that city.

Of the 103 companies reporting, but eighteen declared dividends (five of these being in Greater New York), the total dividends amounting to $3,069,465, of which the five Greater New York roads paid $2,512,374, leaving a balance of only $557,091 to be divided among the remaining thirteen dividend paying roads. Six of the dividend paying roads showed a deficit after so doing. Eight of the 103 street surface railroads mentioned have gone into the hands of receivers during the past four years.

In addition to the above mentioned eight companies, at least twelve or fifteen have gone out of business entirely or saved themselves from going into receivers' hands by making some arrangement with the bondholders.

Briefly, the above report shows that the small and medium sized street surface railroads in New York State, and in fact all the roads with the exception of those in the very largest cities, are struggling along under the most discouraging conditions.

I submit the following significant figures:

1st.—Showing a proportion of net income paid in taxes by street surface, elevated and steam railroads of the State of New York, during the year 1898.

STREET SURFACE RAILROADS

The net income after deducting operating and miscellaneous expenses, interest on funded debt, rentals, etc., not including taxes	$5,139,722
Taxes paid in 1898	1,439,250
	$3,700,472

Percentage of net income paid in taxes, 28 per cent.

ELEVATED RAILROADS

The net income after deducting operating and miscellaneous expenses, interest on funded debt, rentals, etc., not including taxes	$1,929,327
Taxes paid in 1898	886,853
	$1,042,474

Percentage of net income paid in taxes, 46 per cent.

STEAM RAILROADS

The net income after deducting operating and miscellaneous expenses, interest on funded debt, rentals, etc., not including taxes	$29,356,598
Taxes paid in 1898	8,543,587
	$20,813,011

Percentage of net income paid in taxes, 29 1-10 per cent.

2d.—Statement of percentage of dividends upon the capital stock of the street surface, elevated and steam railroads of the State of New York, for the year 1898.

	Cap. Stock.	Div. Paid.	Per Cent.
Street surface railroads	$132,844,303	$3,069,465	2 3-10
Elevated railroads	49,224,352	1,200,000	2 2-5
Steam railroads	771,452,304	14,546,582	1 9-10

The above statement demonstrates that the transportation companies of the State of New York are bearing all the burden of taxation they can stand, and are already paying a large proportion of their net income into the public treasury.

The sum of $1,683,195,749 is invested by the combined transportation companies of this State in road-bed and equipment. A large portion of this enormous amount invested—representing the capital stock and bonded indebtedness of the several companies—has been sunk in a depreciation of the value of both construction and equipment and in expenditure for replacement made necessary thereby, particularly by street surface railroads for the development of mechanical traction, especially electrical, the operation of which for the past decade has been largely experimental, necessitating frequent expensive changes of station and car equipment, and the consignment to the scrap pile of costly machinery, which necessarily had to give way to more improved and modern equip-

ment; also the expenditure incurred in the construction of experimental electrically operated roads, both overhead and underground, which have been tried and have proven a failure, both from the standpoint of profit and operation.

In many instances where horse street railroads were purchased for the purpose of installing with electricity, the entire equipment, for which high prices were paid, proved absolutely valueless to the purchasers.

In the early days of electrical traction enormous prices were charged for equipments of all kinds; for instance, ten years ago $3000 and upward was the price charged for a car equipment which to-day, owing to its crude and undeveloped condition, is worthless, and which can be replaced by a modern, up-to-date outfit for $720.

Without going into details, I would state in a general way, that the same rule applies to track and overhead construction, to car bodies and appurtenances, all of which have to be kept up to date and carefully maintained to meet the requirements of an exacting public.

The interest paid upon that portion of the bonded indebtedness, sunk by depreciation of values, and expended for replacement by the several street surface railroad companies of the State, in order that the city or village wherein their respective roads are located, might be properly subserved, is a material and permanent burden imposed upon each individual road which should be taken into careful consideration in the adjustment of the important question of taxation.

The sum of $164,161,692 was paid out in operating expenses in 1898, the greater portion of the amount being for labor, proving the benefit of these institutions, and demonstrating the fact, when taking into consideration the immense amount of money invested and the cost of operation, that the net income as shown by the above statement is small, and proves conclusively that the proposed tax imposed upon the railroad companies of this State would be unjust, unfair and undeserved.

Two years ago the Legislature of this State passed a gross earning tax bill, imposing upon street surface railroads a tax of 1 per cent upon gross earnings (while the tax law affecting steam railroads remained unchanged). This measure imposed a serious additional burden upon provincial street surface roads, particularly the non-dividend paying companies.

The street railroad companies of the smaller cities of this State are entitled to consideration and relief, rather than additional burdens. In fact, they must receive such consideration and relief, otherwise the number of street railroad companies in receivers' hands will be materially increased. Furthermore, the imposing of additional taxation upon street railroads will thwart the splendid growth and development, which they have successfully inaugurated throughout the State, and curtail the convenience and comfort of the people, and stop the increase of assessed valuations (particularly of suburban property), they have materially assisted in building up, as it goes without saying that extensions and new roads will not be constructed with a franchise tax confronting them.

We ask that you adhere to your message of March 27, and respectfully submit that the bill should not receive your sanction until it becomes operative for the entire State. As it now stands, if it becomes a law, Greater New York will escape this year, while the country roads would suffer. We maintain that this would be an unjust distinction.

Air Brakes on European Street Railways

[*From Our Regular Correspondent*]

To Germany belongs the credit of having had the first experimental electric railway in the world, but many years later, when it was proposed to operate the street railways by electricity, the conservative authorities imposed many restrictions which impelled the managers to adopt power brakes in cases where American managers would consider the hand brake quite sufficient. The very general use of trail cars has also been a factor in encouraging the employment of continuous brakes, as by them the service of an extra man on the trail car for operating the hand brake, may be dispensed with. The Standard Air Brake Company, of New York, early recognized that in Germany there was a good field for its apparatus, and this company has now more than 600 cars equipped. Its first installation was made three years ago on 150 motor cars and 100 trailers of the Grosse Leipziger Strassenbahn, which has been adding to its equipment every year until it now has some 250 motor cars, all with air brakes.

At first the motormen were permitted to use the air brakes only when hauling trailers, but, it being so much easier to stop the cars by means of the air than by hand, they naturally used them also when without trailers, if they thought they were not liable to be detected; they are now expected to use the air at all times. This brake had been tried in other cities, where the conditions were similar to those in Leipzig, and was condemned, but it would seem that the failure must have been due to lack of proper understanding and care. Each car comes into the repair shop every three months to have the motor cleaned out, and the compressor is then taken off the axle and cleaned; every second time the eccentric strap has to be closed about 1-32 in. to take up the wear, and occasionally the axle bearings are closed, but the parts being enclosed in an oil-tight casing, wear very slowly. A pint and a half of good oil is put into the casing every two weeks. The management takes considerable interest in the brake and has devised a special screen that is put directly on the pump head over the air inlet, instead of using the screen that is ordinarily put under the car seat. About all the track is paved, so there is very little dust, but to prevent the oil from dropping on the pavement, a drip pan is hung under the pump that catches all that works through the axle bearings. In how many American cities would objections be raised to such drippings?

The city of Prague, in Austria, owns its street railways and is equipping them electrically as fast as possible; they are putting on the "Standard" brakes and have forty out of the first hundred already in operation. The very long and steep grades are favorable to the use of air brakes, as the power used in controlling and stopping on the descent is supplied by the momentum of the car, and the motors have a chance to cool off after the heavy work of ascending the grade. These single truck cars, with channel iron body frames, have the truck running well out toward the ends, and the parts of the two are so intermingled that it is very difficult to distinguish which is which, and the reckless way in which expensive forgings are employed in the construction of these, and, in fact, a large part of the German cars, would bankrupt an American car on a line which will run a little way into the suburbs, and they favor for the denser city traffic and they are being equipped with power brakes, although the limit of speed is still below that of similar American practice.

The accompanying illustration shows a handsome car built on lines familiar to American readers; this is one of a hundred on the Munich Electric Railway, equipped, as are the Leipzig cars, by the Union Electricitäts Gesellschaft, of Berlin, and supplied with air brakes. Nuremberg is putting twenty-four of this same type of car on a line which will run a little ways into the suburbs, and they will be equipped with air brakes. All of the above equipments are of the axle, eccentric driven compressor type, which the Leipzig experience has proven to be well adapted to the needs of city service, but the Grosse Berliner Strassenbahn is trying a later type of spur gear driven axle compressor that is doing very good work. All of this company's electric cars that run into the center of the city are double-truck, and are operated by storage batteries, within certain limits, and by trolley when outside. The cars are naturally very heavy (over 30,000 lbs.) and it has been impracticable to brake them by hand, so the company adopted the expedient of making the stops by short circuiting the motors, which, however, has been found to be severe on the motors, and liable to make a jerky stop. Here the trucks have a great pivotal movement, so it is impracticable to have a mechanical connection between them for the brakes; by putting a cylinder on each truck, the mechanical connection is unnecessary and the brake shoe pressure is perfectly equalized betwen them.

Another car illustrated is one on the Siemens & Halske Company's Berlin-Treptow combination overhead and underground trolley line, on which an extended trial was made by that company of the "Standard" motor compressor air brake equipment before adopting it for the Düsseldorf-Krefeld interurban electric railway, a road about 13 miles long, built on its own right of way. This latter road is operated by 40,000-lb. motor cars with 29-ft. bodies and vestibuled platforms, carried on pivotal trucks; these have a strong plate frame that forms pedestals for the journal boxes. Each box has bolted to its under side a semi-elliptical leaf spring which is parallel with, and just outside the plate frame. The ends of these four springs are fixed to the plate frame by means of stirrups, and the cars ride very smoothly. Each truck carries on its inner axle a 75-h.p. motor with armature mounted direct on the axle. The current is taken from a flexibly supported trolley wire by two of the Siemens & Halske standard low trolleys, of such length that when the direction of the car is reversed the trolley throws over without any attention on the part of the employees; switch points never give trouble as the trolley can't get off. The contact part is renewable and made of an aluminum casting of inverted U section, ¾ in. wide, 1¼ ins. deep and 3 ft. long; it is kept well greased and gives good satisfaction.

This same motor compressor type of air brake is used in large numbers on the Upper Silesia Interurban Electric Railway, which is an interurban road with 75 miles of line connecting a number of cities in the coal mining and iron smelting district of Eastern

Germany, an open rolling country that reminds one of Nebraska. The gage is but 29½ ins., and the company has at present fifty double truck motor cars and fifty double truck trailers, all equipped with air brakes, and more have been ordered.

The only other air brake for street railways that is used in Germany is Riesinger's "spring pressure" brake, which, as its name implies, makes use of a strong conical spring of steel of a rectangular section, and with a long range of action, as the braking power. The rod to which the spring pressure is applied is also connected to a diaphragm similar to that used in vacuum brakes, in such a manner that when compressed air is admitted to the chamber, the spring action is overcome to any desired degree, thereby reducing the brake pressure or throwing it off altogether. Thus air pressure must be maintained in the train pipe and diaphragm chambers while running, and to apply the brakes air is allowed to escape, giving a braking force equal to the difference between strength of spring and the pull of the diaphragm. This is, therefore, an automatic brake, as the parting of the coupler will allow the air to escape and the springs will make an emergency application. The hand brake must, of course, operate in the reverse from the ordinary, i. e., it must be pulled off to effect a release. This brake is used on the Bergische Kleinbahn, near Elberfeld.

ELECTRIC CAR IN MUNICH

Brussels is situated at the base and on the side of a very considerable hill, and the finest boulevard runs well up on to it and down again, having thus two steep grades, each about three-quarters of a mile long. One of the tramway companies has a line running from the Southern Railway station, through this boulevard, to the Northern station, a distance of 3½ miles, and it is operated with single truck cars drawing trailers. On account of the grades, a city ordinance requires that these trains be equipped with automatic brakes, and the road has therefore supplied the twenty motor cars and their trailers with Westinghouse automatic air brakes. Each motor car carries on its roof two main reservoirs 12 ins. in diameter and 12 ft. long, which are charged, at the southern terminus, by a stationary compressor situated in the power station not far away. They use a maximum pressure of 105 lbs. per sq. in. and run it down to 50 lbs. The balance of the brake equipment is similar to that used on steam railways. One charge will last for 12½ miles, making 100 stops with motor car and trailer. The railway people express themselves as being well pleased with the brake, but do not use it as yet when running the motor car without the trailer.

In France the electric tramways have hardly done anything with air brakes, although there is a growing interest in them. Here, as in European countries generally, the trail car meets with considerable favor, and the Department of the Prefect of Police of Paris has recently issued an ordinance to the effect that all street railways running into Paris and operating trail cars must be equipped with a continuous power brake, that may be applied from any platform of the train without previous warning to the "wattman," as they term the motorman. The Thomson-Houston Company, which built and operates the Bastille-Clarenton line of the Cie Générale Parisienne de Tramways, proposes to use trailers there, and as the electric brake does not fulfil the requirements of the Prefect of Police as regards trailers, they are trying the "Standard" geared axle compressor equipment. The engineers, preferring the less complicated direct air system to the automatic with triple valves, etc., fulfil the requirements by carrying a reservoir pipe back through the trail car, and providing on each platform a stop cock, by means of which the conductor can let the air from the reservoir into the brake cylinders whenever necessary. The police also require that all cars shall be provided with a brake that will stop the car (loaded to its allowed capacity) on a 2 per cent down grade, within 65.6 ft. when running at a speed of 12.5 miles per hour. This the hand brake will do if the slack is well taken up before the signal to stop is given. The engineer of the Prefect of Police states that in a test made by him of a loaded car equipped with air brakes, it was stopped, without using sand, on a 2.2 per cent grade in 33 ft. when running at 13 miles per hour, which was highly satisfactory. The illustration shows one of the motor cars of this line, and it will be noted that steps are provided only at two diagonally opposite corners, also that the platform extends into the body for a distance equal to half the width of the car. Swinging doors are provided so they may be swung out from the sides until they meet, shutting off the narrow outside platform,

BERLIN CAR WITH AIR RESERVOIR ON ROOF

at the forward end, and forming a little vestibule in which eight second class passengers may ride, six standing and two sitting on little folding seats that shut up to permit of swinging the doors open when this end is to the rear. Eighteen first class passengers may sit inside, and ten more second class may ride on the rear platform. The fare within the city is, first class, four cents, and second class, two cents.

For many years tramways have been operated in Paris by steam or compressed air motor cars hauling trailers, and these are equipped with the Soulerin automatic air brake. The compressor, placed on the front platform (the cars always run one way) which is occupied by the driving mechanism, stands vertically, and is actuated, through a bell crank under the car, by an eccentric on the

PARISIAN ELECTRIC CAR WITH STEPS AT SIDE

axle with a long connecting rod, so the vertical motion of the car body has practically no effect on the stroke. This brake has given very good satisfaction, but the speed rarely attains 15 miles per hour; this compressor could not be used on electric cars, as its location on the platform would be objectionable, as also the long connecting rod.

In England, on the Liverpool Overhead Railway and the Waterloo & City and the City & South London, the Westinghouse automatic brake is used, the air being stored in reservoirs carried on the train. The latter road, however, is equipping its new electric locomotives with Standard compound motor-driven compressors and will have twelve in service shortly. The Central London Underground Railway electric locomotives will all be equipped with motor-driven compressors supplied by the Christensen Engineer-

ing Company. The surface tramways have begun to use the air brake, fifteen of the "Standard" geared axle compressor equipments having been put on the double truck cars of the Liverpool Tramways last fall. There are some long, steep grades in Liverpool that make it advisable to equip the heavy cars with power brakes. This corporation also operates fifteen trains of single truck motor cars with trailers, supplied by a German firm, and these are equipped with electro-magnetic brakes. The Potteries Tramway Company, of North Staffordshire is to operate with single truck cars hauling trailers, and they are equipped with the same air brake that is used on the Liverpool tramways.

Power brakes have become a necessary part of the equipment of double truck cars, and of single truck ones on roads with heavy grades, or where trailers are used, and the use of the compressed air for this purpose is meeting with increased favor.

Electric Railway Construction in Germany

George P. Pettit, American Consul at Düsseldorf, writes as follows:

"Of the more important German cities, Aix la Chapelle, Brunswick, Chemnitz, Dresden, Hamburg, Hanover, Leipzig, Munich and Stettin have almost completely abandoned horse cars and are supplied with electric roads. In the cities of Berlin, Breslau, Cassel, Cologne, Frankfort-on-the-Main, Düsseldorf, Barmen, Elberfeld, Königsberg (East Prussia), and other places, horse lines are being converted into electric roads, and most of these have suburban electric roads completed. A large number of electric lines are being constructed in the country districts about Aix la Chapelle, Bochum, Gelsenkirchen, Düsseldorf, Vohwinkel, Elberfeld, Barmen, Elbthal, Essen, Krais Hoerde, Reisengebirge, Waldenburg (Silesia), Witten-Ruhr, and in the mining districts of the Saar (Southern Rheinland) and in Upper Silesia. In thirty-five cities and districts, not mentioned in the above lists, electric roads were in the course of construction on Sept. 1 last, in nine of which the roads were completed and put into operation before the close of the year; so that at the beginning of the year 1899, there were seventy-seven cities and districts in the Empire supplied with electric roads. In thirty-five of these places, extensions were being made to the lines in operation Sept. 1, 1898, some of which were completed before Jan. 1.

"The following is a comparative statement of electric railway construction in Germany for the past three years:

DESCRIPTION.	August, 1896.	September 1, 1897.	September 1, 1898.	Per Cent. of Increase in 1898 Over 1897.
Power houses	42	56	68	21.4
Miles of roads	362.2	594.7	888.1	21.4
Miles of tracks	530.7	842.1	1,204.9	43
Motor cars	1,571	2,255	3,190	41.5
Trailers	589	1,601	2,128	32.9
Electric power, kw	18,560	24,920	33,333	33.8

"Adding the roads put in operation since Jan. 1, 1899, it is estimated that there are now 930 miles of electric roads, with a total of 1300 miles of tracks in Germany. Many American cars are used.

"From the city of Düsseldorf there are now four suburban electric lines completed: From Düsseldorf to Crefeld, about 12 miles; from Düsseldorf to Rattigen, about 8 miles; from Düsseldorf to Benrath, about 6 miles, and from Düsseldorf to Kaiserswerth, about 5 miles."

An Outside Paint

Thomson Brothers, of 395 Park Place, Brooklyn, N. Y., manufacture a paint for the protection of all kinds of metal and wood structural work, etc., and which, it is claimed, will greatly prolong the life of such constructions. The company exhibits a number of testimonial letters testifying to the fact that the Thomson paints, wherever applied, have shown unusual qualities in retaining their life in pigment color and body to a remarkable degree, and effectually protecting metal work from corrosion and rust.

One firm, after using these paints for from seven to eight years, states that it has not re-painted its freight car bodies which were treated with the Thomson paint in 1891, 1892 and 1893, and that the roofs of the same cars did not require repainting until after four years of hard service. Another concern says, "we cannot recommend Thomson's paint too highly;" and another states it is the greatest coverer and cheapest paint of which it has any knowledge. The Government Building, at the World's Fair, Chicago, was painted with this brand.

The Functions of an Electric Truck, I

BY EDGAR PECKHAM

I read with much interest and some amusement the article on the Parallel in the Development of the Locomotive and the Electric Truck, by John A. Brill, in the May issue of the STREET RAILWAY JOURNAL. The comparative description of the early English locomotive and a recent type of heavy passenger locomotive intended for use on American railways seems to me to be particularly unfortunate, and especially so in the deductions drawn that, because the two engines are not alike, the bar type of frame is more suitable than a plate frame for use on an electric car. The writer forgot, or perhaps he is not aware, that the great majority of the locomotives of the world have plate frames, and that the bar frame is a distinctively American characteristic and is by no means acknowledged to be the best by builders and users outside of the United States. He also overlooked the fact that the duties required of a locomotive and of an electric truck are entirely different.

It would have been better, it would seem, to have discussed the stresses which an electric truck has to bear, and then to have considered the most desirable means for carrying an electric car,

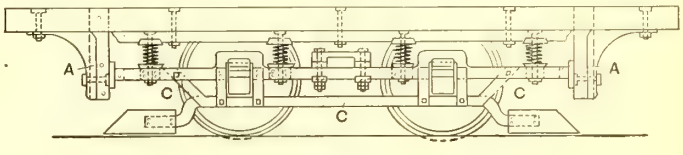

FIG. 1

rather than to have branched off into a field where the conditions are absolutely dissimilar.

The function of a locomotive frame is not to sustain a load, as is the case with an electric truck frame, but to hold the wheels in alignment and resist the stresses resulting from the operation of the machinery. The electric truck, on the other hand, is built to carry a load and the horizontal stresses are those involved in the propulsion of its own burden. As the power is applied directly to the axle, these horizontal stresses, due to propulsion, drop to comparative insignificance, leaving the principal function of the

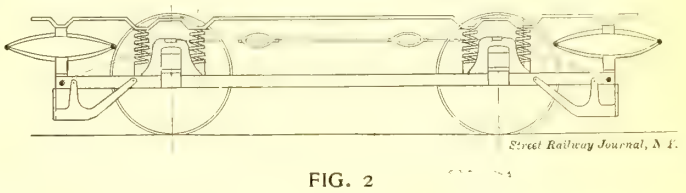

FIG. 2

truck that of carrying the load, which must be done in such a way as to make the car ride easily and without oscillation. Both experience and theory dictate that to eliminate the oscillation, a long spring base is necessary, so that, as a result, practically all of the single trucks on the market carry the greater part of the weight of the car at the ends of the truck.

With these facts before him, the writer of the article under consideration says that "it is hardly surprising that the truss idea took such firm hold upon the builders who had thought of the subject in a superficial manner only. The truss is naturally the first thing that comes into the mind, because the load seems to be the most important factor of the problem."

This statement is apparently accompanied by a lapse of memory, which can be easily filled in by a reference to Figs. 1 and 2, which are examples of the first attempts to introduce the principle of the truss into truck construction. Fig. 1 is that of the braced cantilever construction, which has been found to be so thoroughly suited to the needs of the service for which it was designed, and so capable of being adapted to all varieties of cars that it has been adopted, and is in use by the largest electric railway companies of both this country and of Europe, over 10,000 of these trucks being in constant service. Ever since their introduction these trucks have been continuously and are still replacing the solid forged truck frames, for the reason that their design is based upon correct mechanical principles.

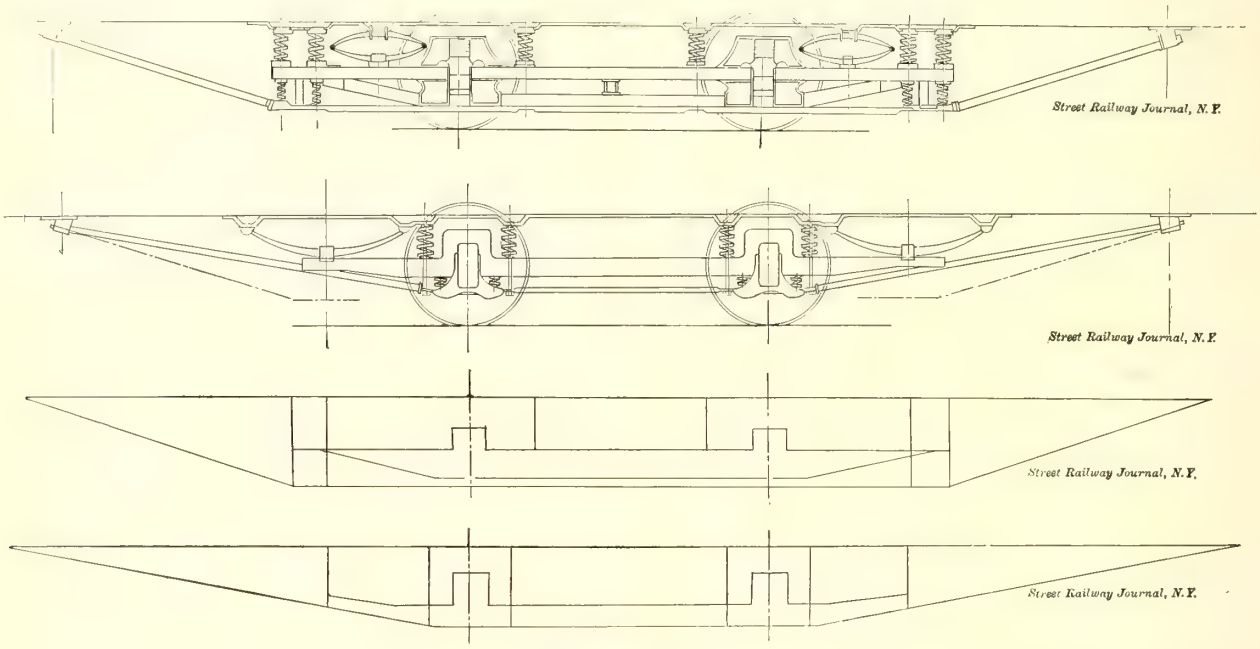
The truck shown in Fig. 2, on the other hand, was an attempt to utilize the suspension principle in the framing of the cantilever car truss. This design was found in practice to involve the constant taking up of the stretch of the rods, coupled with the liability of the ends of the cantilever to droop. These conditions

caused the Brill Company to abandon the use of the suspension rods and substitute therefor the plain bar frame.

In a recent discussion of the subject in the London "Electrical Review," by Henry E. P. Cottrell, A. M. I. C. E., some illustrations are given, which are here reproduced in Figs. 3 to 6. Figs. 3 and 4 are examples of the standard extension trucks, as made by the Peckham and Brill companies respectively, and drawn to the same scale. Figs. 5 and 6 are diagrams showing how the cantilever trusses have been combined by the two companies. The differences betweeen the two are clearly apparent, and it is equally apparent that the form shown in Fig. 5 is superior to that of Fig. 6, and that, with the same wheel base, the spring base of the type shown in Figs. 3 and 5 is much greater than that of Figs. 4 and 6, and that the inclination of the raking members of the extension truss is much more favorable for affording support in the former than in the latter, also that whereas the underframing of the car body serves to materially increase the strength and resistance of the same to bending moments at the ends or to counteract the tendency to drooping into the former, this is not at all the case with the latter truck. Referring to these diagrams the writer mentioned says:

"The adaptation of the extension principle in the truss shown in Figs. 3 and 5 is evidently the *only* practical solution of the problem involved in the ever increasing demand for longer car bodies supported on a single four-wheel truck of a limited wheel base."

Could anything be more widely removed from the above opinion of an English expert than the closing sentences of the article in the Street Railway Journal, where it is stated that: "A little practical experience was required to show the fallacy of the idea," that is, of the truss. To be sure there is some reason for considering the truss idea fallacious when experience in practical construction was limited to the design shown in Fig. 2, and which, not being susceptible of improvement, was naturally abandoned, especially when practical experience agreed so perfectly with the theoretical analysis, that has been carried out to embrace even the type for which Fig. 2 was abandoned as shown in Figs. 4 and 6. In short, for extended car bodies, the unbraced solid brackets prove entirely inadequate, as is shown by the attempt to employ a modified truss frame under the car by the advocates of the single bar truck, but hampered by the unfortunate design of the truck proper, the result has been unsatisfactory.



As a final argument, Mr. Brill claims to believe that the riveted construction used in the cantilever bridge truss frame is an objectionable feature, and thinks that the rivets will become loose under service, but the same argument would apply to all made-up structural work, including railroad bridges, trusses and viaducts, in which the jars and strains upon the members are greatly in excess of those encountered under an electric car. If there was any foundation for this claim that riveted girders are structurally weak, every railroad bridge in the country, and every supporting span on elevated railroads would be unsafe for travelers. As a matter of fact, the riveting in truck construction is carried on and surrounded by all the facilities of an up-to-date machine shop, with pneumatic machines, so that the construction is certainly superior to that possible outside of a shop, but the experience with all structural work in the country proves that there is nothing stronger or more durable than riveted construction, when properly done.

It is, of course, quite impossible within the limits of a single article to discuss the distribution of the stresses as applied to an electric truck and a comparison of the same in relation to those applied to a locomotive. I, therefore, reserve such a discussion for a future article, and meanwhile merely wish to reiterate the fact that an electric truck does not perform the functions of the framing of a locomotive, that its main purpose is to carry the weight of the car and motors, and that this is the viewpoint taken by competent engineers, and that when they are called upon to design the two, they plan in accordance with principles suited to the work in hand, and do not make a thoughtless jump to the conclusion that because American engineers consider a bar frame as best suited to their locomotives, it follows that the same construction is to be blindly followed in the building of an electric truck.

(To be Continued.)

New Rail Bond Catalogue

The Protected Rail Bond Company, with general offices at Philadelphia, Pa., has just issued an exceptionally attractive catalogue of its rail bonds and rail bonding tools. The catalogue consists of thirty-two pages and cover, and illustrates fully all of the various types of "Protected" rail bonds manufactured by the company. The Protected Rail Bond Company has acquired all of the patents and the rail bond business heretofore conducted by Messrs. J. M. Atkinson & Company, of Chicago, and the Forest City Electric Company, of Cleveland, and is now manufacturing the "Protected" bonds under these patents.

FIGS. 3 TO 6

The product of the company will be sold through two general sales agencies, located in Philadelphia and Chicago. Messrs. Mayer & Englund, of Philadelphia, Pa., will have full charge of all business in the eastern part of the country, including all export business. Messrs. J. M. Atkinson & Company, of Chicago, will have full charge of all business for the western part of the country. District agents will be appointed to work under supervision of the general agencies.

The rail bonds manufactured by this company are so well known that they need no introduction to street railway managers and engineers, as they have been sold in large quantities all over the world for the past three years. The facilities of the Protected Rail Bond Company for manufacturing its bonds are most excellent, and provisions have been made to take care of the unusually large business already secured for this spring. The factory, which is located in Cleveland, Ohio, is now working night and day to keep up with the orders, and the season of 1899 is just opening up.

The Protected Rail Bond Company will shortly announce its readiness to place upon the market its complete outfit for punching and bonding rails with hydraulic tools, on which experiments and tests have been conducted for the past year. Two or three important contracts have been taken for the installation of "Protected" bonds with these hydraulic tools, and the result is being watched with interest by many leading engineers.

Electro-Magnetic Traction System

For some years the Westinghouse Electric and Manufacturing Company has been perfecting an electro-magnetic system for traction purposes. A short line equipped with this system was operated successfully for several years on North Capital Street, Washington, and it has been in active daily service in the yards of the Westinghouse Company for the past four years.

The Government has recently installed an electric railway on this system at the United States Navy Proving Grounds at Indian Head on the the Potomac. The entire line is about 3 miles in length, part being operated by an overhead trolley, and the remainder by the Westinghouse magneto-electric surface contact system. The railway track crosses the firing line, where the overhead wires would be in danger from projectiles, and an underground or surface system was imperative. A part of the track is shown in Fig. 1. The line is equipped with two 100-h.p. Westinghouse freight locomotives shown in Fig. 2, and one combined passenger and freight locomotive of 50 h.p. The principle and operation of the magneto-electric system will be best understood by referring to Figs. 3 and 7.

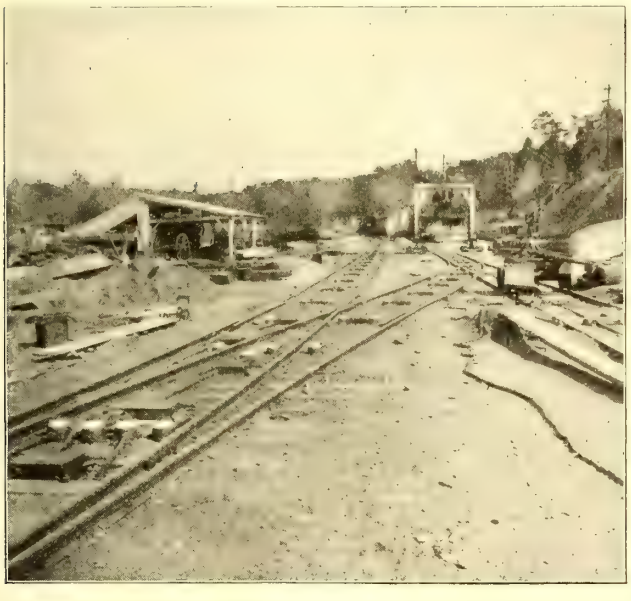


FIG. 1.—VIEW OF TRACK

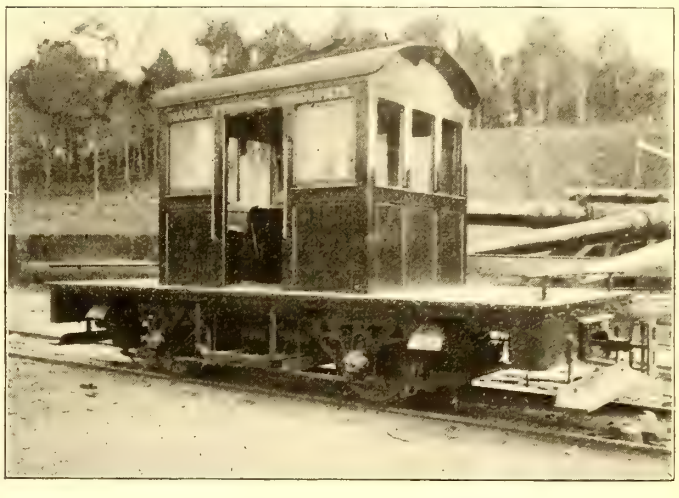

FIG. 2.—ELECTRIC LOCOMOTIVE

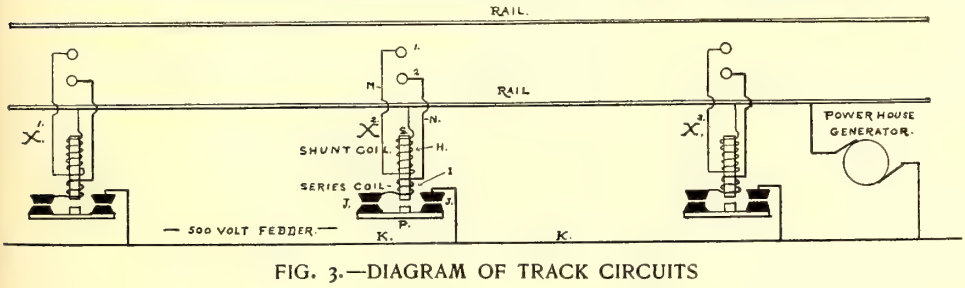

FIG. 3.—DIAGRAM OF TRACK CIRCUITS

Electro-magnetic switches, X, X, X, encased in water-tight casings, are installed at intervals of about 15 ft. along the track to be operated. Each switch is provided with two windings, I and H, which are connected by the wires N, M, to two cast iron contact plates, 1 and 2, which are mounted on suitable insulators and placed between the running rails. Each car to be operated on this system is provided with two spring mounted T steel contact shoes, Q^1 Q^2, six cells of storage battery, and a small motor transformer in addition to the usual controllers and motors. The contact shoes, Q^1 Q^2, are mounted at the same distance apart as the contact pins 1 and 2, so that as the car advances along the track the shoes will make contact with the successive pairs of pins in turn, always being in contact with at least one pair, as the length of the bar exceeds the distance between any two pairs by several feet. To fully understand the operation of the system, suppose a car is standing on the track over the switch X^2, the contact shoes Q^1 and Q^2 being then, of course, in connection with the pins 1 and 2 respectively. The first step is to pick up the current, i. e., render the pins 1 and 2 alive. Switch A is first closed, this completes the circuit from storage battery D, through the motor transformer, which immediately starts up. As soon as transformer is up to speed, requiring only a few seconds, switch B is closed; current then passes from transformer through wiring R R, contact shoe Q, pin No. 1, coil H to ground. This current passing through the coil H, magnetizes the core S, which, in turn, attracts the armature P, closing the switch and establishing connection between the pin 2, and the 500-volt main feeder K, K, through wiring N, coil I, and contacts; switch C is now closed and switches A and B opened, the transformer then stops, the switch X^2 is kept closed, however, by the current flowing from the main feeder through lamp L connection R, M, coil H to ground. The car now proceeds on its way, current from the main passing through coil I, contact bar A^2 connection T, to the controller and motors in the usual manner. When the car has advanced a short distance the contact bars make connection with the pair of buttons connected to switch X^3. Current then passes from the bars through the shunt coil of this switch, closing it, and connecting it in its turn with the main feeder.

As soon as the bars leave the pins 1 and 2, current ceases to pass through the coils I and H, and switch X^2 immediately opens by gravity, leaving the pins connected to it dead and harmless. As connections with the main have already been established through switch X^3, the opening of switch X^2 does not interrupt the flow of current to the car. It will be observed that all the current passing to car from main through switch contacts J, J, passes through the heavy coil I, holding the switch firmly closed, precluding all possibility of switch opening while current is passing through contacts, even should circuit through coil H be interrupted. Although the act of "picking up the current" requires some time to describe, it takes in practice only a few seconds. The battery and transformer are employed only to lift the first switch, for after that has been closed, the contact shoes bridge the main voltage over from one set of pins to another, closing the successive switches, without further attention from the motorman. If it is desired at any time to render the section "dead," over which the car is passing, this may be immediately accomplished by opening switch C. Figs. 4 and 5 show the practical installation of this system for yard work, and is the form installed at Indian Head Proving Grounds.

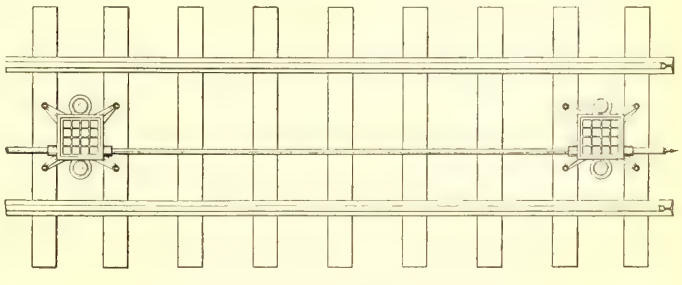

FIG. 4.—PLAN VIEW OF BOXES

The switch, switch box, and contact pins as shown, are made up into a complete unit which is wired up before leaving factory

and shipped ready for installation, only requiring to be set upon the ties and connection made with the main feeder. This spider-like structure consisting of box rim, insulator receptacles, and supporting arms, is made in one malleable iron casting. The lid, which is removable, is a separate casting. A wooden box coated with tar is fitted into a recess provided for that purpose in the bottom of casting and is bolted in place. In this box is placed the electro-magnetic switch which is covered by an air-tight bell shown in Fig. 6, and which will be described more fully later on.

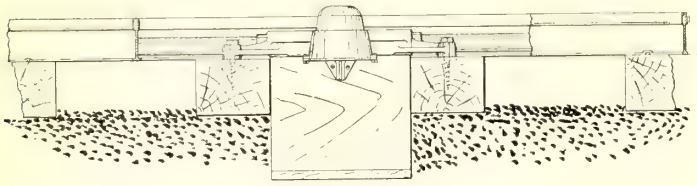

FIG. 5.—SIDE ELEVATION OF TRACK

The insulators, Fig. 5, which are mare of a special composition, are cemented in the tapered cups and backed up by the malleable iron plate. The contact pins are mounted on top of these insulators, and stand, when placed in position, 1½ ins. above the running rail.

The simplicity in the wiring required for this system should here be remarked. One wire only, and that the main feeder, is required to be run, and this is encased in iron pipe and passes

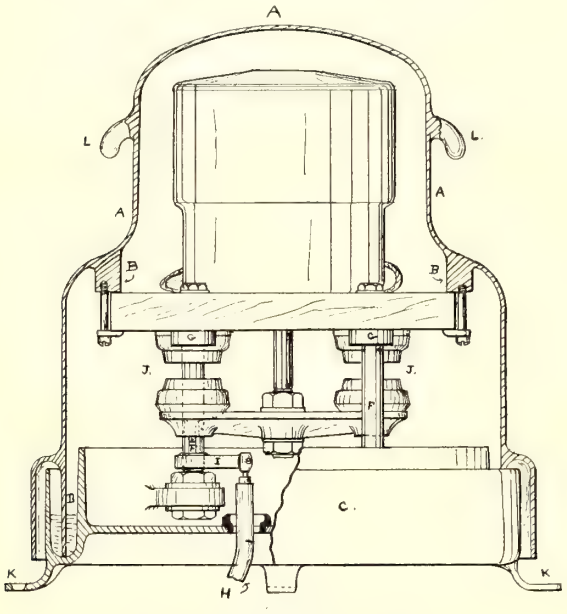

FIG. 6—SECTION OF BOX

directly through each switch box. No additional wires are used interconnecting the coils or contacts of adjacent switches, this objectionable feature being entirely eliminated. The contacts are of carbon and their life seems practically unlimited, as we have been unable to detect any appreciable wear on the contacts of switches which have been in continual use for three years.

Fig. 6 clearly shows general arrangement of switch, bell and

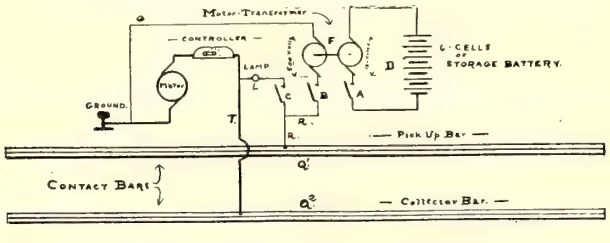

FIG. 7.—DIAGRAM OF CAR CONNECTION

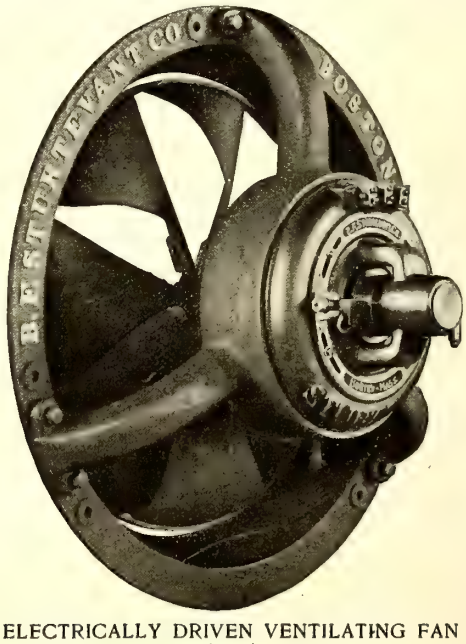


pan. The switch is mounted upon a marble slab, which is secured in the circular bell by means of screws to the bosses, B, B. The bell A is provided with lugs L to facilitate handling, and also with a double lip which fits into and over the annuallar groove D, in pan C, when bell is in position; thus providing a simple and effective method of protecting the switch from moisture. The bells may be entirely submerged in water without affecting the operation of the switches. Connection from the several cables is made to split pins, which are supported upon lugs in the pan C, and insulated therefrom. The switch is provided with receptacles which correspond to these pins, so that it may be quickly and readily removed for examination, without the necessity of disconnecting any wires. All switch parts, bell, pans, insulators, etc., are made interchangeable.

On the turn tables are placed two switches and pairs of buttons. A light section of steel, bent to the radius of turn table pit, is fastened on insulators to inner side of same, and permanently connected to main feeder. A spring contact finger mounted on turn table, makes contact on face of T section, thus keeping up constant connection with the main regardless of position of turn table.

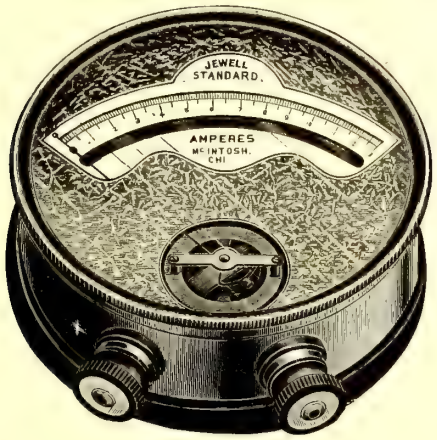
A New Type of Electric Propeller Ventilating Fan

Since the B. F. Sturtevant Company, of Boston, Mass., has entered extensively upon the manufacture of electric motors and generating sets, it has been carefully studying the problem of the manufacture of a compact, efficient and convenient type of electric ventilating fan. Exhaustive tests were made with different types of wheels. The result is made clear by the accompanying engraving, showing a view of one of its electric ventilating fans which has just been put upon the market.

The fan wheel has eight blades rigidly attached to a spider at the center, and held in place by a hoop at the periphery, at an angle of approximately 30 degs. The angle is increased in such a manner that as the center is approached, the theoretical velocity of the air remains practically constant. In other words, the delivery edge is helical, and the air is picked up on the inlet edge of the blades at low velocity. When well under the influence of the blades, it is accelerated to its maximum velocity with the least amount of slip. The result is an extremely efficient wheel.

ELECTRICALLY DRIVEN VENTILATING FAN

The motor likewise has been the result of very careful study in the attempt to provide a light machine, entirely enclosed, and at the same time to avoid the excessive temperature which is incident to the operation of most enclosed motors. The result is a machine capable of continuous operation for ten hours, with a maximum temperature rise of not exceeding 30 deg. F. A practical efficiency of over 80 per cent is obtained even with the small-sized motors, and an excess load of 75 per cent above the rated capacity may be carried without sparking, and without changing of brushes. This feature, combined with the small temperature rise, allows of carrying temporary overloads with impunity.



The bearings are self-oiling and self-aligning, and are fitted with phosphor-bronze sleeves, which are removable from the outer ends of the boxes.

The wheel is partially enclosed in a conoidal inlet ring, which decreases the frictional resistance of the entering air, and furnishes at the same time a rigid support for the motor, to which it is attached by the tripod hanger.

These fans are built in sizes from 18 ins. to 120 ins., with motors designed for either medium or maximum speed, and to run at any ordinary direct current voltage. A speed controller is always provided, by means of which the fan can be efficiently operated at different speeds.

Standard Portable Meter

A new portable standard electrical measuring instrument, for direct current only, is being placed upon the market by the McIntosh Battery & Optical Company, Chicago, and is shown herewith. Its construction is exceedingly rigid, fitting it to withstand the rough usage to which portable instruments are frequently subjected. This meter is of the d'Arsonval pattern, having a coil moving in the field of a permanent magnet. It has uniformly spaced scale divisions and an adjustable dial, so that should the

PORTABLE AMMETER

index become bent it is but the work of a moment to set it to zero. The instrument is dead beat.

The permanent magnets are made from imported magnet steel, and are thoroughly aged before being placed in the instrument. The springs are made from a special low-resistance phosphor-bronze alloy, and are of a very fine temper. The series coils in the volt meters and the shunts of the ampere meters are made from an alloy having a zero temperature coefficient.

A neat hardwood carrying case is provided with each meter. The volt meters have a resistance of about 120 ohms per volt of scale; *i. e.*, a 0-150 volt meter has a resistance of 18,000 ohms.

New Open Cars for Brooklyn

The Brooklyn Heights Railroad Company, of Brooklyn, N. Y., is now putting in service a large number of thirteen-bench, bulkhead open cars, which, on account of the careful way in which the details have been worked out, are worthy of special attention from street railroad men. These cars are built by the J. G. Brill Company, and are 35 ft., 9 ins. over the corner posts and 45 ft. 2 ins. over all. The greatest width, which is over the drip rail, is 7 ft. 10¾ ins. At the sills they are 6 ft. 6 ins. there are two platforms, each 3 ft. 11 ins. long, and a seat is placed on each of them. The height from the head of the rail to the underside of the sill is 25 ins. The height over all is 8 ft. 11 ins. A single step is used which is 18 ins. from the head of the rail, with a 15-in. riser. These cars are mounted on a pair of Eureka maximum traction trucks with the usual 4-ft. wheel base and wheels of 20 ins. and 30 ins. diameter. These long, large and comfortable cars are especially fitted for the heavy work which the Brooklyn street railways experience during the Coney Island season. The power is furnished by two W. P. 50 motors. Although plated sills are used, and the Brill Company in the construction of these cars has taken great pains to make everything as strong and substantial as necessary, the total weight of the car complete, without motors, is only 18,250 lbs.

There are four stationary seats set back to back against the bulkheads, and nine reversible seats in the body of the car. All of these are furnished with round corner seat end panels. The seats and backs are of slat. The interior finish is of ash, with a plain three-ply quartered oak head lining with the usual advertising moldings, etc. The guard rails are of solid ash, made in one piece, extending from bulkhead to bulkhead. These slides on the hickory grab handles which are set in bronze sockets. The platforms are closed with leather covered chains. The glass in the raised roof is of beveled edge throughout. There are electric headlights on each platform. The curtains are of pantasote mounted on Hartshorn fixtures and come all the way to the floor. These cars when closed have nearly a perfect protection from the weather the same as an ordinary closed car. The curtains being waterproof and fitting closely are much more effective than the old type. The registers are operated by a half-inch square rod running along the posts with ringing handles at the proper places. The edges of the sill plates are carefully rounded so that there is no danger of catching the foot in entering or leaving the car. The seat arms are made in such a way as to give great strength and to have the least possible projection in the seat. The seats themselves are spaced 2 ft. 7 in. This is not so great as to invite overcrowding, and yet it gives ample space for comfortable seating. The details throughout have received an unusual amount of attention. The car is tastefully painted in cream and maroon, with striping and lettering of aluminum. Taken in connection with the solid bronze trim, which is used throughout, these cars are among the handsomest recently turned out from the Brill shops.

Demand for Brake Shoes

The "Compo" brake shoes, as manufactured by the Composite Brake Shoe Company, of Boston, Mass., and which have been in very extensive use for some time on the electric street railways of the United States, are now being introduced into other fields. By making a few minor modifications the shoe has been adapted for use on all kinds of heavy carriages and wagons, fire apparatus, automobiles, etc.

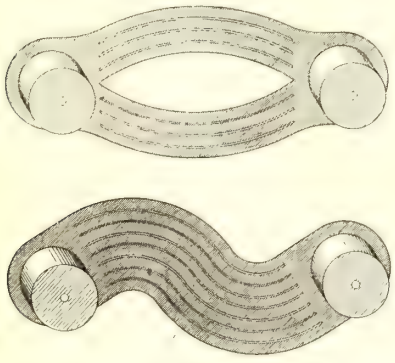
As is well known, these shoes are made of cast iron, with sock-

NEW OPEN CAR FOR BROOKLYN

ets into which cork inserts are compressed. The cork is tenacious, and being elastic, gives excessive braking or frictional results without the gripping effect of contacting metals. It wears uniformly with the iron; not more, nor faster.

In proof of the fact that the Compo shoes are well suited to the requirements of heavy wagons, such as fire apparatus, etc.,

it is stated that the fire department of Boston, after a very severe test, has ordered these shoes placed on twenty engines, twenty hose wagons, and ten ladder trucks in that city.



The Compo shoe is, of course, also well adapted to the needs of steam railroads, and is very extensively used on passenger and freight cars throughout America. In a recent test on the Boston & Maine Railroad a shoe fitted with cork inserts ran 58,794 miles from March 18, 1898, to March 1, 1899, and when taken off was still good for service. During this period it had made 14,688 station stops; the average miles per hour, including stops, being 30. The shoe weighed when put in 64½ lbs., and when taken out 51¾ lbs., showing a loss of metal of 12½ lbs. The average thickness of the shoe when new was 2⅛ ins., and when taken out it was 1 5/16 ins., showing an actual wear of 13/16 in. This record gives 4700 miles for each lb. of metal lost by wear. There are a number of very heavy grades on the route over which the test was made.

A One-Piece Rail Bond

A device that promises to perfectly fulfill the long existing demand of street railway managers for a one-piece protected copper bond is being brought out by Elmer P. Morris, of New York city, the well-known dealer in electric railway specialties and supplies.

The new bond is shown in the accompanying illustrations. It is drop forged compleett, with terminals and body in one piece from pure copper, thus insuring the best possible carrying capacity. To give flexibility, and to permit the bond to be used under varying conditions, a number of parallel slits are cut, running the length of the body as shown. The bond is then spread apart or bent at the middle, according to the circumstances under which it is to be used.

The bond is applied in the usual way, terminals being furnished in any size desired, ranging from ⅝ in. to 1 in. or more in diameter. The connecting strap or body is made of any capacity, from that of 00 copper wire up to 00000000. Mr. Morris reports that there are orders already in hand for this new device to keep the works busy for six weeks to come.

TWO FORMS OF ONE-PIECE RAIL BOND

Heavy Engine Building in Milwaukee

The home and foreign demand for heavy engines for electric railway work continues to be urgent, and it is becoming impossible to fulfill desired dates of delivery. The E. P. Allis Company, of Milwaukee, one of the best-known heavy engine builders in the world, has now actually going through its works in various stages of construction, nearly 125,000 h.p. of heavy engines for electric railway service, among these being engines for the following well-known companies:

Metropolitan Street Railway Company, of New York, eleven engines of 4500 h.p. (each maximum capacity 7000). These are the largest engines of any kind ever built in this country and perhaps in the world. The cylinders are 46 ins. and 86 ins. x 60 ins., and the distance from the foundation to top of cylinders is about 38 ft. 3 ins. The shaft is hollow, being 37 ins. in diameter at center, and having an opening 16 ins. in diameter extending the entire length. The journals are 34 ins. x 60 ins. Three of these engines have been delivered and the fourth is ready for shipment.

The Boston Elevated Railway Company, two engines, 4500 h.p. each, of substantially the same type as the Metropolitan engines, but without the cross connections between high and low pressure cylinders, which, in the New York engines, secure independent operation of each side, in the event of breakage.

The South Side Elevated Railway Company, of Chicago, two engines of 2500 h.p. each.

Metropolitan Street Railway Company, Kansas City, one engine of 2500 h.p., and one engine of 1200 h.p.

Metropolitan West Side Elevated Railway Company, of Chicago, two engines, 2250 h.p. each.

North Jersey Street Railway Company, Jersey City, one 2000-h.p. engine.

Northwestern Elevated Railway Company, Chicago, three 2000-h.p., and one 1000-h.p. engines.

London Electric Lighting Company, three 1600-h.p. engines.

The Milwaukee Electric Railway & Light Company, two 1600-h.p., and two 1000-h.p. engines.

Toledo Traction Company, one 1600-h.p. engine.

Consolidated Street Railway Company, Grand Rapids, one 1300-h.p. engine.

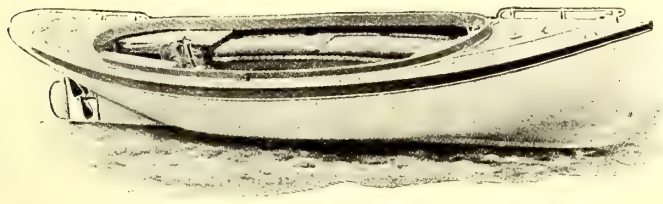
New Orleans & Carrolton Railway Company, one 1300-h.p. engine.

Richmond, Va., three 1000-h.p. engines for railway service.

LARGE ENGINES FOR NEW YORK

Bristol, Eng., four 1000-h.p., and the London Tramways Company, four 1000-h.p. engines.

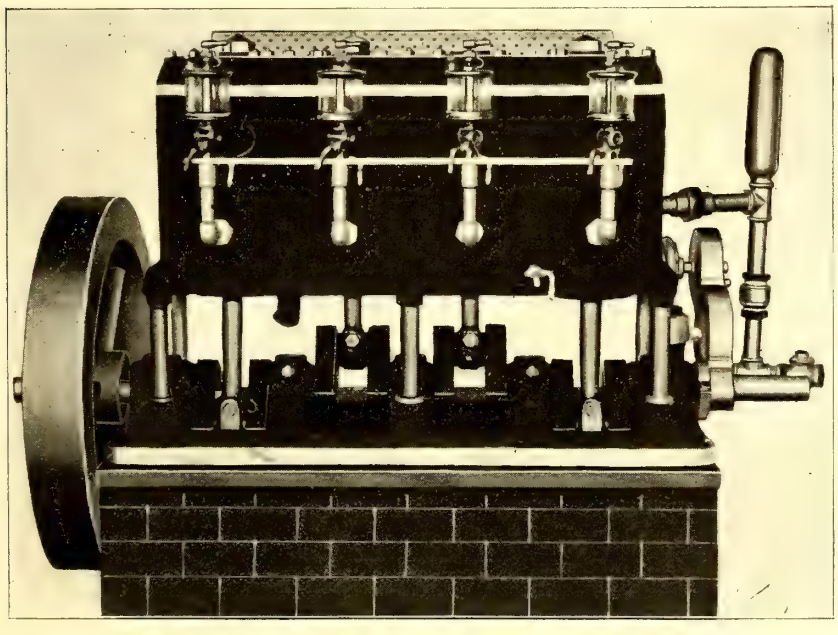
Among the smaller railway engines building in the same shops are a 900-h.p. for Sioux City, and 800-h.p. for Buenos Ayres, Argentina; two 600-h.p. for Cork, Ireland; two 500-h.p. for Lebanon, Pa., and two 400-h.p. for Anderson, Ind.



It is announced that the Fifth Avenue Stage Line, of New York city, has been purchased in the interest of the Metropolitan Street Railway Company, and will be used as a feeder to that line. It is also reported that automobiles will be put in operation at once along the route, in place of the old horse busses.

Vapor Launches

To street railway companies owning pleasure resorts containing bodies of water of sufficient depth to float light boats there can be no better investment than a number of neat, strong open launches. It has been proven beyond question that the patrons of such resorts will take advantage of a boat ride when no other form of amusement will attract their attention. The number of launches and the price to be paid for them will, of course, depend entirely upon local conditions.



One of the best types of pleasure launches, and at the same time one of the least expensive, is the gasoline or naphtha boats, for which C. B. Sterling & Co., 120 Liberty Street, New York, are the agents. The boats handled by this concern are made entirely from the best materials, on the most approved lines, and of any size from 12 ft. to 53 ft. in length.

The motive power is furnished by an improved type of marine gas engine, using a vapor of either gasoline or naphtha for power. The vapor is exploded in the firing chamber of the cylinder by an electric spark from a small chemical battery regularly at each revolution. It is claimed that these engines are absolutely safe,

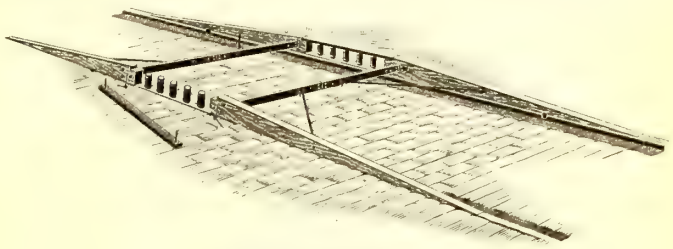
VAPOR LAUNCH

there being no vapor of water, gasoline, naphtha or alcohol under pressure, no storage of dangerous pressure, and no boiler or retort. Therefore, there is no possibility of explosion from overpressure. Special care has been given in the designing to secure the greatest simplicity possible, and the use of all complicated parts liable to derangement has been avoided. The engine occupies a small space at the stern of the boat, leaving the cockpit

FOUR-CYCLE VAPOR ENGINE

free of machinery, and can be safely operated by any one of ordinary intelligence without any previous engineering training.

These engines are also made in the four-cycle type, having an explosion every other revolution. These are built for from 8 h.p. to 40 h.p. The company has recently booked a number of orders for large boats, one of which is to have twin screws.



New Line in Wisconsin

The Citizens' Traction Company, of Oshkosh, Wis., is building a 14-mile line to Neenah, and has closed a contract with the Falk Company of Milwaukee for the entire and complete construction of this line. The Falk Company has contracted with the Babcock & Wilcox Company for boilers, with the General Electric Company for generators, with the St. Louis Car Company for double-truck cross-seat cars, and with William Wharton, Jr. & Co. and Pennsylvania Steel Company for rails and track material. The power will be sent from the Oshkosh power stations to a rotary converter substation 9 miles away, and a General Electric six-pole, 300-kw., three-phase generator will be used, with 6600 volts transmission.

A Portable Hose Bridge

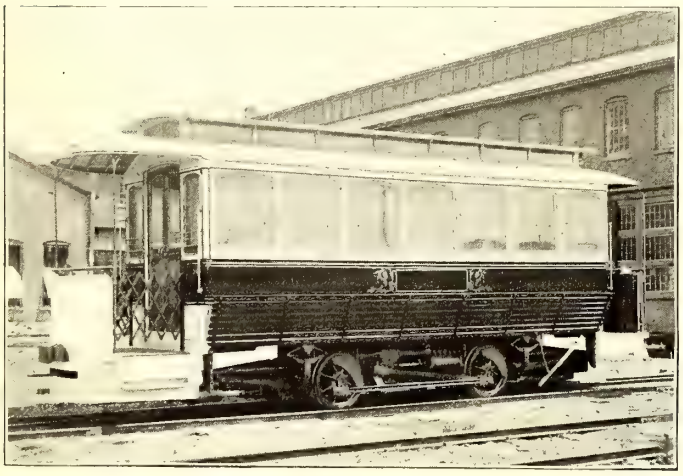
In the accompanying engraving is shown a portable hose bridge designed for the purpose of preventing blockades due to fires. As is well known, traffic on a street railway line is often interrupted for several hours owing to the necessity of fire companies running their hose across the track, although the fire may be several blocks off. These delays can be entirely avoided by the use of this bridge.

As will be seen from the cut, the device consists of two parallel trusses, 16 ft. in length, fastened together by two double-hinged

PORTABLE HOSE BRIDGE

joints. When opened the joints form a cross-bar, and become a rigid connection between the two trusses, each cross-bar being locked in position by two iron rods, which are permanently fastened to the truss by an eye and staple at one end, and when in use are hooked into the center of the cross-bar at the other end. These rods have four braces, which render the bridge perfectly rigid. A steel lug an inch in length projects downward from the inside of the lower rail of the trusses at each of their ends. These lugs are slightly beveled, and will fit against either a T, flat, or grooved rail equally well. There is no downward pressure on them, their mission being simply to keep the bridge from sliding off the rail sideways. When the device is in position these lugs fit just inside of the inner side of the rail.

The total weight of the bridge is about 117 lbs., and it being contractable to 9 ins. in width, four of the machines may be readily carried on the ordinary repair or tower wagon. There are six pockets, 4 ins. square, for the reception of hose.



Changes in Dublin

Owing to the recent death of Dr. Carte, by which the chairmanship of the Dublin Union Tramways Company was made vacant, William Murphy has been appointed by the company to that position. At the same meeting William Anderson was elected to the place on the board of directors filled by Mr. Murphy, and was also appointed managing director. His service of twenty-six years as secretary and manager of the company, during which it has been steadily and increasingly successful, makes Mr. Anderson's appointment to his new position a particularly desirable one. R. S. Tresilian has been appointed secretary of the company to the place made vacant by the change of position of Mr Anderson.

The suit brought in the Circuit Court of the United States for the Northern District of Illinois by the Falk Manufacturing Company vs. the American Improved Rail Joint Company and Andrew S. Littlefield, for alleged infringement of letters patent No. 587,718, dated August 10, 1897, for a "portable melting furnace," was duly argued and submitted to the court in pleadings, proofs, illustrative exhibits, etc., introduced by complainant and defendants, but before the rendering of the decision by the court suit was withdrawn at the request of the complainant, who assumed costs.

Compressed Air Cars in Chicago

A test is being made of compressed air as a motive power on some cars being operated on the lines of the North Chicago Street Railroad Company. The work is being done under the auspices of the Compressed Air Motor Company, of Chicago. The cars are modeled after those that were operated for a year on 125th Street, in New York, and have all the added improvements suggested by the experience secured with this type of cars in New York. The system employed is known as that of the Hardie, and

COMPRESSED AIR CAR

Robert Hardie, chief engineer of the company, and well known in the field of compressed air development, is in charge of the installation, and superintends the operation of the cars. To bring out the new features, a brief description of the equipment will follow: The cars are 28 ft. long over all, and weigh, when fully equipped, including the truck and mechanism, about 9 tons. The wheels are 26 ins. in diameter, and are coupled after the manner of locomotive practice. The power is supplied from two cylinders, each 7 ins. x 14 ins., mounted one on each side of the truck, from which the piston rod connects with the crosshead, and this is connected to the coupling rod by means of a rocker arm. The valve gear is controlled by a regular Stevenson's link, with a cut-off, and is operated by separate eccentrics. A variation of cut-off is effected by the reversing link.

Air brakes are employed for controlling the car, and the brake cylinder is located under one end, near the platform. The controlling handle is located against the dashboard, and in connection with this is a by-pass starting-valve.

The air is stored in reservoirs, which are located under the seat and in other convenient positions on the truck beneath the floor of the car. The tanks under the seats are 9 ins. in diameter, and extend the full length of the car. All these tanks are of seamless tubing, manufactured in Germany by the Mannesmann Company, and bear the marks and guarantee of the inspectors of the German Government, by whom every tank is tested before shipping. The testing pressure is 4860 lbs. to the square inch. The charge for operating the cars is carried at an initial pressure of 2200 lbs. to the square inch, and the tanks included in the equipment have a capacity of 51 cubic feet. The pressure is automatically reduced, however, to 150 lbs. to the square inch, and is then passed through a reheating tank, and is delivered to the cylinders at the latter pressure. The reheating tank consists of a shell of boiler plate, and is 18 ins. in diameter x 7 ft. in length, and when the car is ready for service is reheated by live steam at a temperature of about 300 degs. The air is admitted to a perforated pipe in the bottom of this tank and bubbles up through the water, and in its passage absorbs heat and moisture, which adds to its economical value and prevents the ports from freezing from the excessive low temperature attending the expansion of the charge.

It is interesting to note in this connection the economical feature of reheating the air. From some tests that have been made, it was found that a car with a full charge of cold air was able to make a trip of 8 miles, while with the same charge and the air reheated as above described a total of 15 miles was easily made, a gain of 7 miles having been secured with an estimated expenditure of 10 lbs. of coal, the amount theoretically required for raising the water to the necessary temperature. This estimate is based on the theory that there are about 8000 available heat units to a pound of coal. For starting the car the valves are so arranged that air under increased pressure can be delivered to the cylinders, enabling the cars to start easily and positively under all conditions, without regard to the position of the cut-off valves. As soon as the car is under way the high pressure is cut off, and the cylinders work under a normal pressure of 150 lbs.

In order to provide the necessary pressure for operating the cars two Norwalk three-stage compressors have been installed in the tension room of the Clark Street cable power system, and steam for operating them is taken from the boilers of the station. A nest of twenty reservoirs of the same type as those described for carrying the charge on the car is provided near the compressors. These are arranged in four rows and five tiers, and are divided in two sections of ten each, each section being coupled at one end by means of copper tubing to a single pipe, which is fitted with a valve and operating wheel. These tanks are 22 ft. in length and 9 ins. in diameter. In the process of compressing a charge the air passes through a coil of pipes contained in a large tank filled with water. From this it passes through a condensing device, by means of which the condensation from the moisture in the atmosphere is tapped off, so that only comparatively dry air enters the storage tank.

Mr. Hardie has been experimenting with compressed air as a motive power since 1876, and is now confident that he has brought his system to a commercial success. He states that the only drawback or delay in the introduction of compressed air as a motive power has been the difficulty of getting sufficient capital to demonstrate the system on a large scale. He claims that the compressed air motor has passed through the stages of evolution very much as the electric motor; that while the early types of electric motors were virtually failures in the light of present experience, they have now reached a degree of commercial efficiency, and he believes that with ten years of experience with the compressed air motors, under the same care and interest that has been expended on the electric motor, that the air will have surpassed the latter and become as universally popular. The Compressed Air Motor Company in Chicago was virtually organized four years ago, at the time the experiments were undertaken in the East, but very little has been done, as the company has been awaiting results of experiments made by the Eastern company. The organization of the company is now composed of the following: Henry D. Cooke, president; Alexander C. Soper, treasurer; William E. Selleck, assistant treasurer, with Robert Hardie as chief engineer. W. J. Chalmers, of the firm of Chalmers & Co., engine builders of Chicago, is one of the directors.

Portable Air Compressing Apparatus

The Christensen Engineering Company, of Milwaukee, Wis., has recently put a very neat and compact compressing apparatus on the market, to be used wherever electric current is available

PORTABLE AIR COMPRESSING APPARATUS

for general purposes, such as cleaning car cushions and operating pneumatic tools for chipping, calking, riveting or drilling. The apparatus herewith illustrated weighs about 1400 lbs. and is strictly

portable and self-contained. The air compressor has a capacity of 50 cu. ft. of free air per minute, and is of the same style and pattern as the company is putting on the market for air brake purposes. The manufacturers are prepared to furnish this kind of portable apparatus in all sizes, ranging from 10 cu. ft. to 300 cu. ft. free air per minute.

All working parts run in a bath of oil, the motor being arranged on the top of the compressor, and connected to the compressor crank shaft by means of a gear and pinion of special pattern, first introduced by the Christensen Engineering Company, said gear and pinion being composed of sections of a true helical form, which construction makes their operation practically noiseless and increases their durability, it is stated, fully 25 per cent over that of the ordinary straight faced spur gear and pinion.

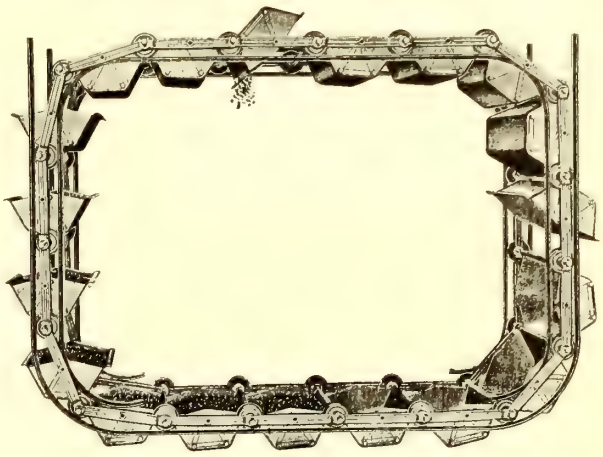
The compressor delivers air into the reservoirs from which a hose connection is taken, and the compressed air thereby conveyed to the point where it is to do the work. The action of the compressor is controlled by means of an automatic governor, which operates by the air pressure accumulated in the reservoirs, in such a way that the motor stops whenever the pressure is at a maximum and starts when it is at minimum, with any desired variation between the two extremes.

The compressor is not provided with a water jacket, as it is claimed, in this form of construction the compressor will run half the time without any undue heat. This makes the apparatus much more practical than if it were necessary to have cooling water around the cylinders and the back heads, thereby introducing extra complications and need of care taking.

The box which encloses the motor compressor, together with the electric apparatus in connection with same, is all water tight, and is so arranged that access is readily had to all the various parts of the apparatus by simply opening doors arranged in the box for that purpose. This apparatus is used in connection with riveting the structural iron work now being done on the new Post Office Building in Chicago.

Well Known Supply House

The Falk Company of Milwaukee has absorbed the Cloos Electrical Engineering Company of Milwaukee, manufacturers of devices for the controlling of high voltages, especially oil switches, in which a special acidless oil is used, imported from abroad, by means of which arcing between high voltage terminals is absolutely done away with. Switching, which formerly required many careful precautions on the part of station attendants, is now rendered almost as safe as that of ordinary direct-current work. The well-known mechanical ability of the Falk Company is a guarantee that its work in this line will become well known and widely used.



The construction department of the Falk Company has recently obtained some important contracts, including one for the change of a 5-mile cable line of the Metropolitan Street Railway in Kansas City to electricity, and a bulk contract for the complete construction of a 14-mile line between Oshkosh, Wis., and Neenah.

The company's gearing and special work departments have also large contracts on hand, and the cast welding business is assuming constantly larger proportions all over the country, and, in fact, the world. The Falk Company has just closed a contract with the Yerkes lines in Chicago for three complete cast welding equipments and a license to weld joints under the Falk patents. Equipments have also been furnished to the Boston Elevated Railway Company, and a full equipment of welding machinery was recently sent to Buenos Ayres for work being done there under the supervision of Kincaid, Waller & Manville, the well-known London tramway engineers.

In fact, the work of the Falk Company in all its departments is increasing so rapidly that the present factory facilities have been entirely outgrown, and new ones are being created on a large scale. A plot of eight acres of land has been purchased near the present shops, and is now being prepared for the erection of new shops, in which all the work of the various departments will be concentrated. The machine shop will be 100 ft. x 200 ft. in length. The foundry, which will be equipped for casting steel, will be of the same size. There will be a power house covering 60 ft. x 140 ft., and an office building 40 ft. x 60 ft. Electric motors will be used throughout for driving machinery, the power coming from the company's own power house, and the buildings will be so put up as to make possible large expansions longitudinally. A special spur track from the Chicago, Milwaukee & St. Paul yards in the immediate neighborhood will be run directly through the center of the shops, and large electric cranes will travel longitudinally through the foundry and machine shop for the transference of work in all stages.

Coal Bucket Conveyor

As stated in another part of this issue, the new power station of the Milwaukee Electric Railway & Light Company is equipped with complete coal conveying apparatus. This is manufactured by John A. Mead & Company, of New York City, and is shown in the accompanying illustration. The apparatus consists of an endless series of chain links and cross shafts, mounted on track wheels, and from which the conveyor buckets are pivotally mounted in the chain. The conveyor is supported on, and is guided by the system of tracks through all the various changes of angle or direction in which the conveyor is moved. The chain links are so constructed as to give the proper strength, bearing

COAL BUCKET CONVEYOR

and perfect alignment for the conveyor buckets. There are four links to each section. The conveyor buckets are made out of the best quality of steel plate, and have malleable dump cams riveted to either end, which form the pivotal connection with the chain links, and also for turning the buckets on their pivots for discharging their contents.

The conveyor buckets when on a horizontal track overlap in such a manner as to form a continuous receptacle, and in passing from a lower to a verticle or inclined track the buckets maintain their normal upright position by gravity. By overlaping the buckets the material is delivered into the conveyor at any desired point along the horizontal track through an ordinary chute, having in it a gate to regulate the flow of the material. The material is carried from receiving point to place of delivery without transferring from one system into another and without breakage.

The driving mechanism consists of two hexagonal shaped spider wheels, having rollers in the outer ends of their arms, which bear against the track wheels of the conveyor. The track at the driving point is concentric with the centers of the driving wheels. There is no sliding or lost motion between the driving spiders and the conveyor chain, and consequently no wear. The motion imparted to the conveyor by this arrangement is remarkably even and steady, and any elongation in the centers of the chain links is automatically compensated for by the point of contact between the driver and chain.

John A. Mead & Company have installed this device in a large number of power plants, including the stations of the Chicago City Railway Company, the Southside Elevated Railway Company, Chicago, the Consolidated Traction Company, of Pittsburgh, the Cincinnati Edison Company, and three stations of the Metropolitan Street Railway Company, of New York.

Air Brake Catalogue

A neat brochure, that illustrates in a very forcible manner the simplicity and efficiency of the storage system for air brakes on electric railway cars, is being sent out by the G. P. Magann Air Brake Company of Detroit, Mich. In the Magann system the air is compressed at the power station, and is stored under each car in a reservoir at 300 lbs. pressure. From here it is taken through a reducing valve as required. This apparatus does away entirely with all complicated compressing devices on the car, and, in addition, it is claimed, gives a more satisfactory and reliable pressure at the shoes, preventing skidding of the wheels and "jamming" of the brakes.

Lubrication in Power Plants

BY J. N. EDELIN

In constructing power plants the owners or consulting engineers often say, when the subject of lubrication is approached, "we have not completed the large and more important contracts yet, and when these are completed we will then take up the minor details of our plants." Now, one of the most important necessities of a plant is the proper lubrication of the machinery, and it is one of the points which should be considered in making the original plans. This thought was suggested by a recent visit to the immense power house of the Southern Electric Railway Company, of St. Louis, as well as to the two large power houses of the Missouri-Edison Electric Light Company, of St. Louis, Mo., who furnish the lights for the whole city of St. Louis. To prove the importance of the subject of lubrication, we take the liberty of quoting a few remarks from Herbert A. Wagner, general superintendent, Missouri-Edison Electric Company, who says: "In the six months that we have had our oiling system in use we have effected a saving of over $300 per month in the cost of oil, and $150 a month in wages paid to oilers. All of the saving in wages and about half the saving in oil we attribute to the use of the Siegrist oiling system, the balance being due to the change of the character and price of the oil itself. This apparatus, being entirely automatic, practically does away with oilers, for where we had four we have now only one."

The Siegrist oil pump, as used in this station, is mounted on a highly polished iron table 2 x 4½ ft., on which are four small duplex pumps, two for engine oil and two for cylinder oil. Only one of each set is used at a time; the other is held as a duplicate or reserve, and can be thrown in by a valve in a second, to take the place of the other in case of accident. There are also on the table three steam gages, one for steam pressure, one for cylinder oil pressure, and one for engine oil pressure, and three governors, which regulate and control the pumps, making them entirely automatic. Through suitable piping these pumps are connected to tanks. The engine oil is pumped to all necessary parts of each engine and generator, and a pressure of from 60 to 80 lbs. per square inch is maintained. This pressure is carried constantly throughout the oiling system, no matter how much or little oil is being used, by means of suitable regulating valves, placed in a discharge pipe of each pump and acting to close or open the steam admission.

At each bearing or part to be oiled is located a Siegrist automatic sight feed pressure oil cup, connected to the oil pipe system. The rate of speed of each oil cup can be regulated at will by a thumb-screw provided for that purpose, but a diaphragm pressure valve in each cup instantly closes the oil drip if the pressure in the system is lowered more than 2 or 3 lbs. One globe valve placed in the supply pipe for the oil system of each engine is therefore sufficient to start or stop all the oil cups on that engine. In closing this valve the flow of oil is stopped within a few seconds at every oil cup whether located in the highest or lowest parts of the engines. This precludes any waste of oil after the engine is stopped.

Mr. Wagner states that hot journals or bearings belong to the past, for with this system it is possible to use three times as much oil on the bearings as before and yet effect a big saving over the old gravity system, "which is affected by changes in weather and the feed not being reliable." All the surplus oil is piped back from the drips of the engines and generators to the filters located in the basement, where it is refiltered and repumped by this system over and over again.

For the lubrication of cylinders with cylinder oil the Siegrist automatic sight feed lubricator is of polished brass, and has a 1-in. glass, which allows a free passage for the oil without coming in contact with glass whether in a drop or a stream. This sight feed is also controlled automatically by a diaphragm. There is also a connection from the main pipe of lubricator connecting under the diaphragm, giving the same steam pressure as on top; this causes the sight feed to close if the oil pressure gets below that of steam, and also prevents the oil from backing down in glass. This steam also keeps diaphram hot, thereby heating the oil and allowing it to flow freely.

Influence of Mechanical Draft

Walter B. Snow, a member of the engineering staff of the B. F. Sturtevant Company, of Boston, Mass., and an expert on the subject of induced and mechanical draft, has recently written an interesting article on "The Influences of Mechanical Draft Upon the Ultimate Efficiency of Steam Boilers." Mr. Snow treats the subject very exhaustively, and his paper is a valuable addition to the engineering literature of the day.

He says in part: "Mechanical draft may be applied under either of two general methods, the plenum or the vacuum. Which is to be employed must depend upon the circumstances, for it cannot be asserted that either is unqualifiedly superior under all conditions. As ordinarily applied under the plenum or forced draft method, the air is delivered to the closed ashpit under pressure, and then finds its escape through the fuel on the grates above. Its success depends largely upon the manner of introduction of the air to the ashpits. Under the vacuum or induced method a fan is introduced as a direct substitute for the chimney, creating a vacuum in the furnace and drawing therefrom the gases generated in the process of combustion. As the draft is thus rendered positive and practically independent of all condition except the speed of the fan, it is only necessary to provide a short outlet pipe to carry the gases to a sufficient height to permit of their harmless discharge to the atmosphere."

The author has worked out very carefuly the relative cost of installation, and also the total amount that can be saved by substituting the various systems of artificial draft for natural draft. He states that from actual conditions he has found that the total expense for installing a forced draft plant is only 18.7 per cent; that of a single induced fan and accessories 26.7 per cent, and that of a complete duplex induced draft plant 42 per cent of the cost of building the necessary chimney. In each case the cost of a short steel plate stack for carrying off the gases is included. In other words, if a chimney is estimated to cost $10,000, there can be saved on a basis of these averages the respective amounts of $8,130, $7,330 and $5,800 in the first cost, according to which system of mechanical draft is substituted. It is found that in a plant where the annual fixed charges (including interest, depreciation, repairs, insurance and taxes) of a chimney would be $800, the figures for the various mechanical draft systems would be $462 for the duplex induced draft, $294 for the single fan induced draft, and $206 for the forced draft with one fan. In addition to this the mechanical draft apparatus can be easily placed overhead or on top of the boilers, where it occupies no valuable space, and also leaves the space otherwise occupied by a chimney available for other purposes, in many cases this being an important point, especially where real estate values are high.

Convention of the Ohio Street Railway Association

The annual convention of the Ohio Street Railway Association will be held at Springfield, Ohio, on June 14 next. We are advised by Charles Currie, of Lima, Ohio, secretary of the association, that a special rate of a fare and a third for the round trip will be granted on the certificate plan to those desiring to attend the meeting. A large representation of supply men is expected, and Mr. Currie is desirous of being notified as soon as possible by all who expect to be present, in order that proper provision may be made for their comfort and convenience.

Municipal Ownership in Detroit

The transfer of the street railway lines of the city of Detroit to the municipality has been delayed indefinitely on account of the failure of the city and the street railway officials to agree upon the price to be paid the present owners of the line. The matter will probably be decided in the courts.

Strike at a Truck Works

There was a strike of short duration among the men of the McGuire Manufacturing Company in the early part of May, 250 truck builders and machinists refusing to work over time for less than double pay. The works were shut down for two days, when a compromise was reached by the company putting on a complete night shift, thus avoiding the question of over-time altogether.

The truck which is known as the No. 39, which this company is now turning out for the South Bend (Ind.) Street Railway Company and the Peoria & Pekin Terminal Railway is attracting considerable attention, because of its very peculiar features. A full description of this will appear in the next issue of the Street Railway Journal. The company has begun delivery of the trucks for the Northwestern Elevated, of Chicago.

New Road in Mississippi

One of the best equipped railway lines for its size in this country was opened at Vicksburg, Miss., April 24. The Vicksburg Electric Street Railway is 8 miles in length, and runs through the center of the city, with two or three branches. The company was formed in 1898, and construction work was begun last November. The prime movers in the enterprise have been S. F. Mordaunt, the general manager, and J. C. Schaffer, of Chicago, who furnished the necessary capital for the construction of the road. The power house is equipped according to the very latest methods, and contains two 250-h.p. Stirling and one 200-h.p. Heine boilers; one 300-h.p. Cooper and one 300-h.p. Russell engines, and Westinghouse generators. The road was constructed by the North American Railway Construction Company; the cars were built by the St. Louis Car Company, and the Westinghouse Company furnished the complete electrical equipments. The opening day was a gala occasion, and the cars were received with great enthusiasm by the entire city.

Consolidation in Buffalo Completed

The organization of the International Traction Company is now fully completed, and the following official statement is made of the securities in the company's treasury:

The entire capital stock of the Niagara Falls & Suspension Bridge Railway Company (operating the Niagara Falls Whirlpool & Northern Railway, under a traffic agreement); the entire capital stock of the Niagara Falls Park & River Railway Company, the entire capital stock of the Niagara Falls Suspension Bridge Company, the entire capital stock of the Clifton Suspension Bridge Company, the entire capital stock of the Lewiston Connecting Bridge Company, the entire capital stock of the Queenston Heights Bridge Company, 9985 shares out of a total of 10,000 shares of the Buffalo & Lockport Railway Company, 12,369 shares out of a total of 12,500 shares of the Buffalo & Niagara Falls Electric Railway, 52,094 shares out of a total of 53,705 shares of the Buffalo Railway Company. The Buffalo Railway Company owns the entire capital stock of the Buffalo, Bellevue & Lancaster Railway and the Crosstown Street Railway Company, of Buffalo. The Buffalo & Lockport Railway owns the franchises and other property of the Elmwood Avenue & Tonawanda Railway Company.

It is expected that the total outstanding stock of the above companies will soon be acquired, and negotiations are either in progress or have just been completed for the acquisition of certain other properties in the neighborhood.

The capital stock of the International Traction Company is $15,000,000, of which $10,000,000 is common stock, and $5,000,000 is 4 per cent preferred cumulative stock. The company has no direct funded indebtedness, but the funded debt of the nine constituent companies amounts to $12,548,000, as follows:

	Funded Debt.
Buffalo Street Railway Company	$6,150,000
Crosstown Street Railway Company	2,830,000
Buffalo Traction Company	600,000
Buffalo & Niagara Falls Electric Railway Company	925,000
Buffalo & Lockport Railway Company	500,000
Niagara Falls & Suspension Bridge Railway Company.	518,000
Niagara Falls, Park & River Railway Company	600,000
Bridge companies	425,000
Total	$12,548,000

Personal

MR. ROBERT C. TAYLOR has been appointed chief engineer of the Twin City Rapid Transit Company, of Minneapolis.

MR. W. J. HAMMER contributed an interesting article on the present status of electric railroading in the Independent for May 5

MR. WILL CHRISTY, of Akron, Ohio, has entered upon his duties as manager of the reorganized Akron Traction & Electric Company.

MR. JOHN C. DOLPH, of the Sterling Varnish Company, is making a business trip in Europe, visiting both Great Britain and the Continent.

MR. F. E. FISHER has been appointed superintendent of the Joliet Street Railway Company, Joliet, Ill., succeeding Mr. C. C. Rush, who recently died.

MR. HARVEY R. BOWEN has left the Binghamton Railroad Company, and has accepted the position of chief engineer of the Utica Street Railway Company, Utica, N. Y.

MR. JAMES R. LEDYARD has been given the superintendency of the South Covington & Cincinnati Street Railway Company, taking the place of Mr. T. M. Jenkins, who has accepted a position in St. Louis.

MR. A. G. DAVIDS has been promoted to the position of general manager of the Schuylkill Valley Traction Company, of Norristown, Pa., to take up the duties laid down by Mr. R. M. Douglass, the former general manager.

MR. CHARLES F. MORSE, president of the Metropolitan Street Railway Company, of Kansas City, Mo., will retire from that position on June 1, and will probably be succeeded by Mr. W. H. Holmes, the present general manager.

MR. GEORGE F. GREENWOOD, who recently resigned as general manager of the Consolidated Traction Company of Pittsburgh, has been appointed general manager of the Havana Street Railway Company of Havana, Cuba.

MR. J. F. MACARTNEY, of Macartney, McElroy & Company, made a short visit to this country last month. Mr. Macartney is at present located in London, and reports large business as a contractor for electric railways and tramways.

MR. FRED H. FITCH, formerly with the Chicago City Railway Company, and recently manager of the South Western Missouri Electric Railway Company, has accepted the position of general manager of the Sioux City Traction Company, of Sioux City, Ia.

MR. PHILIP DAWSON, who is connected with R. W. Blackwell & Co., and who is a well-known writer on electric railway subjects, sailed for America, May 20, on the steamship Lucania. Mr. Dawson is accompanied by Mrs. Dawson, and will spend some time in America.

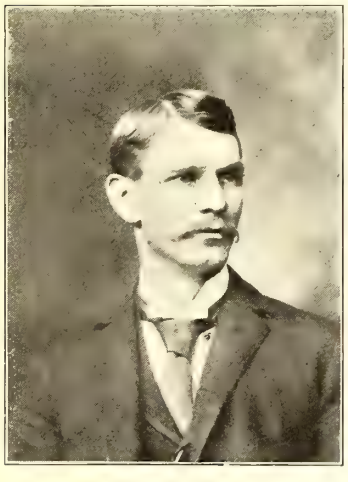
MR. W. F. KELLY, general superintendent of the Columbus Street Railway Company, of Columbus, Ohio, has tendered his resignation, to take effect immediately. Mr. Kelly leaves Columbus to take up more important duties in New York, and will be associated with Mr. Emerson McMillin. He will probably be succeeded by Mr. M. S. Hopkins, electrician of the company.

MR. B. F. HARRIS, JR., and his brother, Mr. N. M. Harris, of Champaign, Ill., formerly the principal owners of the Urbana & Champaign Railway, Gas & Electric Company, have sold their holdings in this property to a party of capitalists of Portland, Me. Mr. Harris and his brother will probably remain in Champaign for the present, at least, but will have no connection with the street railway company.

MR. CHARLES FITZGERALD has taken up his duties as general superintendent of the Consolidated Traction Company, of Pittsburgh, this position until recently having been filled by Mr. G. F. Greenwood. Mr. Fitzgerald has had a very extensive engineer training, both in the street railway and other fields. He has been connected with a portion of the Consolidated Traction Company for some time, having been employed with the Citizens' Traction company since 1889.

MR. H. TALBOT, electrical engineer of the City of Nottingham, Eng., made a trip to this country last month to investigate the subject of electric traction with the view to the proposed installation of an electric tramway in the city of Nottingham by the municipal authorities. Mr. Talbot was accompanied by the city engineer of Nottingham and visited a number of the cities in the eastern part of the country, including New York, Philadelphia, Baltimore, Washington, Buffalo and Boston.

MR. J. H. GIBSON, who was formerly connected with the Baltimore City Passenger Railway Company, has accepted the position of superintendent of the Philadelphia and West Chester Traction Company, whose system is described elsewhere in this issue. Mr. Gibson is well known as a practical street railway engineeer, and previous to his connection with the City Passenger Railway, of Baltimore, held responsible positions in the engineering staff of the Short Electric Railway Company and the Edison General Electric Company.



MR. T. M. JENKINS, who was for some time superintendent of the South Covington & Cincinnati Railway Company, has resigned that position to accept a place with the St. Louis & Sub-

urban Street Railway Company and the St. Louis & Meramec River Railway Company, of St. Louis, Mo. Mr. Jenkins has been very successful in his management of the Cincinnati property, and has developed it until it is now one of the best systems of its size in the United States. He has been extremely popular with all the men on the road, from the officers of the company down to the conductors and motormen, and just before his departure for his new field the employees tendered him an elaborate testimonial banquet. Preceding the dinner a large parade was formed, and Mr. Jenkins was given an old-fashioned serenade and ovation.

MR. C. L. ROSSITER, president of the Brooklyn Rapid Transit Company, of Brooklyn, N. Y., has just returned from a short combined pleasure and business trip to Europe. On his departure, which occurred May 9, Mr. Rossiter was presented with a handsome floral piece in the shape of a miniature electric car, by the employees of the company, the men taking this method of showing their regard. Before leaving, Mr. Rossiter gave out the following notice of appointments recently made on the Brooklyn Heights system. Mr. Ira A. McCormack will be general superintendent, having charge of transportation; Mr. J. C. Brackenridge will be chief engineer, having charge of all construction and maintenance work and the operation of all power houses. A new position is created, that of superintendent of shops, and Mr. F. S. Drake is appointed to fill this. Mr. Lincoln Van Cott is appointed purchasing agent for the system.

MR. ROBERT H. DERRAH, who has been for the last ten years connected with the West End Street Railway and the Boston Elevated Railway Company, in the office of the president, leaves the service of the latter company to enter upon business for himself. He has for several years made a special study of the growing electric railway system of New England, and as the publisher of "Derrah's Street Railway Guide for Eastern Massachusetts" has a wide acquaintance among street railway men. Mr. Derrah is to start upon a new enterprise in this part of the country—the management of electric car excursions for individuals and parties. In England the low price excursion is a popular form of entertainment, and in Boston and its vicinity more attractions of greater diversity can be found than in any other section of the country. While such a business is an experiment in New England, it has great possibilities, and Mr. Derrah leaves the Boston Elevated Railway Company accompanied by the best wishes of its officials and employees to be first in the new field.

MR. RICHARD McCULLOCH, of St. Louis, has been offered an excellent position in Geneva, Switzerland, and is now on his way to take up his new duties. Although his many friends will be pleased to hear of his advancement, they will learn with regret that he is to be absent from this country for several years. Mr. McCulloch's genial nature and unusual ability have attracted to him a wide circle of acquaintances and friends, and he has been especially popular with the employees of the company with which he has been connected. In order to manifest to some extent their appreciation of his sterling qualities, about a hundred of his business and social friends in St. Louis tendered him a farewell banquet at the Planters' Hotel on Thursday evening, May 11. An elaborate menu was prepared, and a number of the leading citizens of the city were present. Mr. McCulloch will superintend the construction of an electric street railway for an English syndicate at Geneva.

RICHARD McCULLOCH

Obituary

MR. C. C. RUSH, who has been the successful superintendent of the Joliet Street Railway Company, of Joliet, Ill., for some time, died on May 3 from injuries received by being struck by an engine on the Chicago & Alton Railroad. Mr. Rush was walking along the tracks, and for some reason did not hear the approaching train. He was born on September 10, 1864, in Champaign, Ill.

CAPT. ALFRED E. HUNT, president of the Pittsburgh Reduction Company, of Pittsburgh, Pa., and a well-known chemical expert, died recently at Philadelphia from illness contracted while in command of Battery B of the National Guard of Pennsylvania in Porto Rico during the Spanish war. Mr. Hunt was born at East Douglas, Mass., on March 31, 1855, and received his technical education at the Massachusetts Institute of Technology. In 1888 he organized the Pittsburgh Reduction Company, to manufacture aluminum, and up to the time of his death was president and general manager of this concern.

AMONG THE MANUFACTURERS

THE BRITISH THOMSON-HOUSTON COMPANY, of London, has moved its Glasgow office from 639a St. Vincent Street to 141 West George Street.

THE FRANK W. MEAD AMUSEMENT COMPANY, of Boston, Mass., is prepared to furnish high class vaudeville specialties for street railway parks, casinos, etc. The company's new catalogue mentions a few of the artists in its employ.

THE UNION BOILER TUBE CLEANER COMPANY, of Pittsburgh, Pa., has begun action in the United States Circuit Court to enjoin Gameliel St. John from manufacturing, selling, or using a certain device for cleaning the interior of boiler tubes.

THE ELECTRICAL INSTALLATION COMPANY, Monadnock Block, Chicago, has just closed a contract for building and equipping the Waupaca Electric Street Railway, Waupaca, Wis. There will be 5 miles of single track. Work was to begin May 24, and the line is to be in operation July 1, giving only thirty-seven days for the completion of the entire contract.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY, of Pittsburgh, Pa., among recent publications, has issued catalogue No. 222, devoted to direct connected railway generators; No. 223, devoted to lightning arresters for alternating current and direct current circuits, and No. 228, on Tesla polyphase induction motors, type C, for constant speed.

THE CLING-SURFACE MANUFACTURING COMPANY, of Buffalo, N. Y., is arousing great interest in its new compound for treating leather belts. A test upon this dressing and the results secured were published in the last issue of the Street Railway Journal. Owing to a typographical error the company's office was there given as New York city instead of Buffalo.

THE MULTIPLEX REFLECTOR COMPANY, of Cleveland, is making a specialty of Schroeder's patent multiplex reflector, and is also manufacturing a complete line of reflectors, headlights and bicycle lamps of every description. The Cleveland City Railway and the Cleveland Electric Railway Company have a number of these reflectors in use, and are thoroughly testing the same.

THE ROBB ENGINEERING COMPANY, of Amherst, N. S., has been awarded the contract for two 230-h.p. engines by F. S. Pearson, of New York, consulting engineer for the Cuban Electric Company. These engines are for an electric railway from Regla, on the opposite side of the harbor from Havana, to Guamacoa, about 8 miles distant.

THE RUMOR that the works of the Pennsylvania Car Wheel Company, of Pittsburgh has been purchased by another company is authoritatively denied by that company. To enable the company to further enlarge its business this year additional property has been taken and its capital stock increased from $100,000 to $200,000, paid in. It is possible that the rumor mentioned was occasioned by these proposed changes.

THE SIMONDS MANUFACTURING COMPANY, of Pittsburgh, Pa., is sending out a new circular on electric railway supplies. A large part of the catalogue is devoted to a discussion of gears and pinions and the different stages of the gears, from the rough casting to the accurately finished wheel are shown. The catalogue also discusses Babbitt bearings, worms, worm wheels and racks, and the Murphy car wheel truing machine.

THE GENERAL ELECTRIC COMPANY, of Schenectady, N. Y., among other printed matter, has issued during the past few weeks the following bulletins: No. 4172, devoted to the G. E. 51 B railway motor; No. 4173, to the G. E. 53 railway motor; No. 4174, to slow and moderate speed motors, type M. P., Form H; No. 4177, to pendant push-button switches; No. 4178, to current indicators, Form B; and flyer No. 2038, to improved practice for series incandescent street lamps.

THE CLAYTON AIR COMPRESSOR WORKS, of New York city, have published a very complete catalogue describing their air compressors for all pressures and for every purpose to which compressed air is applied. The greatly extended use of compressed air has created a positive demand for efficiency and maximum economy in the design and construction of air compressing machinery, and it is thought that the Clayton compressors perfectly fill this demand.

THE CLEVELAND FROG & CROSSING COMPANY, of Cleveland, Ohio, has found its Eastern construction work increasing so rapidly as to require the establishment of an Eastern agency. The company has, therefore, appointed L. J. Buckley & Company, of 257 Broadway, its Eastern agents. F. A. Lapham, of the company, has been spending some time in the East recently, giving Messrs. Buckley & Company such information as will enable them to care satisfactorily for their customers.

THE DREHER GREASE & OIL COMPANY, of 80 Cortlandt Street, New York, is making some very broad claims as to the superiority of its journal and motor grease for electric car work. These claims seem to be well substantiated by the numerous letters testifying to the merit of these greases, and by the fact that a large number of roads are using them exclusively. To any one not familiar with these greases the company will send a sufficient quantity of each kind free to give a thorough trial.

THE GARTON-DANIELS COMPANY, of Keokuk, Ia., reports that since April 1, the sales of Garton lightning arresters have been over double what they have been in the same period of any previous year. The company, in order to keep up its stock, has recently doubled its force of employees, and states that it will be able to meet any requirements for prompt shipments. The new Garton-Dainels kicking-coils and lightning arresters for the protection of small motors, fans, etc., are meeting with a large demand.

FRANK H. MONKS, of 35 Congress Street, Boston, is becoming well established as an expert in the examination of street railway properties in all parts of the country. Mr. Monks has had over fifteen years of practical experience in street railway work, and his reports are of exceptional value to bankers and others desiring to know the exact condition of individual properties. Mr. Monks will be remembered by many as the former general manager of the West End Railway Company, of Boston, now the Boston Elevated Railway Company.

DICK, KERR & COMPANY, of London, Eng., have just secured the order for eighty cars with their complete electrical (Walker) equipment, to be sent to Liverpool, for municipal tramways in that city, and have also secured an order for thirty car bodies for Sheffield. The 110 car bodies will be made by the Electric Tramway & Carriage Company, of Preston, and the Walker motors will be made in America, although a little later they will be manufactured by the new works of Dick, Kerr & Company, to be located also in Preston.

GEORGE A. PARMENTER, of Cambridgeport, Mass., manufacturer of the well-known car fenders, reports that his device continues to give entire satisfaction wherever it is used. In fact, he states that there has not been a single case of fatal accident, or even broken bones, with cars equipped with this guard. Among recent contracts received are one from the Anacosta & Potomac Railway Company, Washington, D. C., for double equipments, and contracts from four companies in the State of Vermont, this fender having been recommended by the Railroad Commissioners of that State.

THE TAUNTON LOCOMOTIVE MANUFACTURING COMPANY, of Taunton, Mass., announces that hereafter its Wainwright department will be represented in New York city by Charles H. Paine, with offices in the Singer Building, corner of Broadway and Liberty Street, and it assures its customers that they may count on prompt and courteous attention to any business intrusted to its care. This company's Catalogue E, for 1899, containing illustrations and descriptions of its feed water heaters, surface condensers and expansion joints, is now ready for distribution, and will be gladly sent on application.

THE DEMING COMPANY, of Salem, Ohio, has published a special catalogue devoted to the subject of pumping machinery for various services, including triplex power pumps, deep well pumping engines for operation by steam engine, gas engine, gasoline engine, oil engine, electric motor and water power. In designing these pumps, it has been the aim of the manufacturers to secure as nearly a uniform flow of water as possible, thus avoiding all shock to the pump parts and piping system. The Deming system of pumps, it is claimed, is somewhat of a departure from the usual type and contains numerous improvements.

THE BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., has received a contract from the La Capital Tramway Company, of Buenos Ayres, Argentina, for a steel water tower, supporting a tank, and having a capacity of 7000 gallons. This is the fifth order received from the same company. The Berlin Iron Bridge Company has also received a contract for a new meter house from the Providence Gas Company. This building is to be 65 ft. wide and 110 ft. long. Also, an order for a purifier house, which is to be 40 ft. wide and 175 ft. long, and three stories high. Also, for a gas holder building 184 ft. in diameter. The entire construction will be of steel framework, absolutely fireproof.

THE BROWN HOISTING & CONVEYING MACHINE COMPANY, of Cleveland, Ohio, is sending out a 175-page illustrated pamphlet describing its various lifting and moving devices, including hand and power traveling cranes of all descriptions, jib cranes, tram rails and trolleys, transfer tables, etc. This firm has had many years of experience in the designing and building of implements of this character and its engineers have made a special study of the best methods of raising and moving heavy pieces of machinery, metal work, etc., in power plants, railroad construction and engineering work of all kinds. The catalogue contains a large number of fine engravings, showing the many different types of cranes doing the work for which they are designed.

JAS. BONAR & COMPANY, of Pittsburgh, Pa., reports orders for Pittsburgh feed water heaters and purifiers for shipment to the following parties: Herman Krels, Knoxville, Tenn., 200 h.p.; Danville Artificial Ice Company, New Orleans, La., 160 h.p.; Oliver Wire Works, Pittsburgh, Pa., 150 h.p.; Duquesne Forge Company, Rankin, Pa., 600 h.p.; J. H. Denhelm & Son, Pittsburgh, Pa., 200 h.p.; Pittsburgh Horse Shoe Company, Glassport, Pa., 600 h.p.; Baker Forge Company, Ellwood City, Pa., 200 h.p.; Pittsburgh Brick Company, Briggston, Pa., 200 h.p.; York Manufacturing Company, York, Pa., 160 h.p.; James H. Baker Manufacturing Company, Tarentum, Pa., 250 h.p.; W. H. Herr, Altoona, Pa., 150 h.p.; Pittsburgh Steel Foundry, Glassport, Pa., 400 h.p.; Altoona &Logan Valley Street Railway Company, Altoona, Pa., 1000 h.p.

THE NEW PROCESS RAWHIDE COMPANY, of Syracuse, N. Y., is meeting with unusual success in the manufacture of its rawhide pinions, and the demand for these supplies is constantly increasing. The company has recently received the following letter from Charles H. Mayer, treasurer of the York Street Railway Company, of York, Pa., which speaks for itself: "I have shipped to your address by Adams Express a rawhide pinion (single reduction—W. P. 30) that has been in use on our road for fourteen months, averaging 105 miles a day. It is one of a lot purchased from you during May, 1897, all of which have given most satisfactory results. Its wearing qualities have been almost equal to that of a steel pinion, the teeth being worn to a knife edge without a break, at the same time leaving the gear with which it was used in as good condition as it was when the pinion was put on."

THE AMERICAN ENGINEERING COMPANY, of Philadelphia, Pa., has under course of construction the Newtown Electric Street Railway, extending from Newtown, Pa., to Doylestown, the county seat of Bucks County. This makes a through connection between Bristol, the largest town in the county, and the county seat. The work will be finished about June 15. The company is also building the Elmira & Senaca Lake Railway, running between Horseheads and Watkins Glen, a distance of 18 miles. The grading is nearly done, and abutments for several of the bridges are in place. The track laying will begin soon, and the road will be completed about the middle of July. The company also has under contract the line of the Michigan Traction Company from Kalamazoo to Battle Creek. Work on this line will begin before June 1, and be completed within ninety days. There is 27 miles of work.

GATES & RANDOLPH have taken the offices and warerooms at 13 and 15 Monadnock Building, Chicago, on the ground floor, formerly occupied by Sargent & Lundie. They are handling the apparatus of the Triumph Electric Company, of Cincinnati, Ohio,

for direct current work; the Warren Electric Manufacturing Company, of Sandusky, Ohio, for alternating work; the Empire Electrical Instrument Company, of New York, portable switchboard, alternating and direct current instruments; F. A. La Roche & Co., of New York, switchboards, circuit breakers and switches, and Sterling Arc Lamp Company, of New York, enclosed arc lamps for all circuits. It is the purpose of this firm to operate a miniature electric lighting plant in its new warerooms, using a Triumph motor running a Warren alternator through a La Roche switchboard, with Empire instruments and transformers, etc., with arc and incandescent lamps and motors running through the same circuit. Gates & Randolph will not only handle electrical apparatus, but will undertake entire contracts for street railway and lighting plants.

MESSRS. P. R. JACKSON & CO., LTD., of Manchester, England, are sending out their new general catalogue and price list, which is a very well printed and splendidly gotten-up book, handsomely bound, and containing about 400 pages, profusely illustrated with good cuts. The volume is not too large for the great field it covers. The earlier sections contain gear wheels of every description, including the well-known double helical-toothed wheels in which this firm was pioneer, and to whom the largest share of credit is due in introducing them into general practice. Pistons and piston rings form another section, while the remainder and the most elaborate part of the book is taken up by the electrical section, including dynamos, motors, traction plant, switchboards, arc lamps, and instruments of every kind. Too high praise cannot be given to P. Slater Lewis, M. M. Inst. C. E., who has compiled a publication which possesses such excellent qualities. Many valuable hints to purchasers are given, and other useful information which should prove of practical value to the English and foreign buyer. The price of the book is 7s. 6d.

THE CONSOLIDATED CAR FENDER COMPANY, of Providence, R. I., reports that orders for car fenders have never been so large as during the past month. It is now supplying fenders to the Metropolitan Street Railway Company, New York; Omaha Street Railway Company, Omaha, Neb.; Ottawa Car Company, Ottawa, Ont.; Des Moines City Railway Company, Des Moines, Ia.; Paterson Railway Company, Paterson, N. J.; Troy City Railway Company, Troy, N. Y., and Union Depot Railroad Company, St. Louis, Mo. It has also shipped a large number of parts of equipments to City Electric Railway Company, Port Huron, Mich.; Hartford Street Railway Company, Hartford, Conn.; Staten Island Midland Railroad Company, Stapleton, N. Y.; Meriden Electric Railroad, Meriden, Conn.; Fair Haven & Westville Railroad Company, New Haven, Conn.; Auburn City Railway Company, Auburn, N. Y.; North Hudson County Railway Company, Hoboken, N. J.; North Jersey Street Railway Company, Jersey City, N. J.; Middletown-Goshen Traction Company, Middletown, N. Y., and Utica Belt Line Street Railway Company, Utica, N. Y.

THE PNEUMATIC SUPPLY & EQUIPMENT COMPANY has been organized under the laws of the State of New York, and has opened an office at 120 Liberty Street, New York. It is the purpose of this company, as its name implies, to deal generally in compressed air equipment, and it will make a specialty of the installation of complete plants, eliminating the division of responsibility which has heretofore existed in the trade. The company is bringing out several specialties in the compressed air line, such as pneumatic oil rivet forges, quick acting hose couplings, and has in addition closed agencies for several standard types of compressors. J. W. Duntley, the president of the Chicago Pneumatic Tool Company, is the president of the new company; E. B. Gallaher, formerly with Patterson, Gottfried & Hunter, is the vice-president and engineer, and W. P. Pressinger, formerly manager of the Clayton Air Compressor Works, is secretary and treasurer. The rapidly widening scope of compressed air application opens a large field of usefulness for the new company, and the character of its incorporators is an assurance of its ability to meet the requirements of the trade.

THE CHRISTENSEN ENGINEERING COMPANY'S shops are overrun with work to such an extent that increased facilities are an immediate necessity, and will shortly be made. From the orders now going through the shops it appears that it is far from correct to suppose that it is the foreign, and not American, street railways which are taking up with air brakes on a large scale, for among these orders are those for a greater or less number of brakes from the following companies: Northwestern Elevated Railway Company, of Chicago; Brooklyn Elevated Railway Company; Twin City Rapid Transit Company, of Minneapolis; Union Railway Company, of Providence, R. I.; Quincy & Boston Street Railway Company; Union Traction Company, of Anderson, Ind.; Brockton (Mass.) Street Railway Company; Detroit, Lake Shore & Mt. Clemens Railway Company; Dayton, Xenia & Bellebrook Street Railway Company; Hingham (Mass.) Street Railway Company; Albany Railway Company; Wason Manufacturing Company, Springfield, and Montville Street Railway Company, Norwich, Conn. All these orders are for independent electric motor compressors and track equipment, and this seems to be the type which is almost universally preferred for city and interurban street railways.

New Publications

History of the Union Traction Company. By Frederick T. Chandler and Percy M. Chandler, of Philadelphia. Paper. 31 pages. Published by the compilers.

This is a descriptive and statistical analysis of the consolidation and development of the street railway properties of Philadelphia. The pamphlet contains a statement of the capitalization of the constituent companies, comprising the Union Traction system, together with the statistics of operation, interest, taxes, etc. A large inset map of Philadelphia showing the complete system is also included.

Red Manual of Statistics. Published by Haven & Stout, New York city. 580 pages. Illustrated.

This manual contains statistics of great value to investors in stocks and bonds, giving, as it does, financial information regarding all the principal railroad, street railway, industrial and other corporations whose securities are handled on the leading stock exchanges in America. This information includes a statement of the capital stock and funded debt, comparative earnings and names of officers and directors. A large number of maps, together with a statement of the high and low record of the securities for the past year, are included.

Liquid Air and the Liquification of Gases. By T. O'Connor Sloane. 365 pages. Illustrated. Price $2.50. Published by Norman W. Henley & Co., New York.

Dr. Sloane is well known as the author of a number of books on electrical subjects, and he has treated his subject in the new book mentioned above in his usual clear style. The entire history of the liquification of gases is given from the earliest times to the present, and the later experiments, particularly of Tripler, are given in great detail. It is difficult at present to gage exactly the commercial value of a cheap method of liquifying air, but the process has wide possibilities of application to the arts, as well as possessing great scientific interest. The book is well illustrated.

Trade Catalogues

Pumping Machinery. Published by the Deming Company, Salem, Ohio. 33 pages. Illustrated.

Cranes. Published by the Brown Hoisting & Conveying Machine Company, Cleveland, Ohio. 175 pages. Illustrated.

Catalogue. Published by the Simonds Manufacturing Company, Pittsburgh, Pa. 15 pages. Illustrated.

Amusements. Published by the Frank W. Mead Amusement Company, Boston, Mass. 32 pages. Illustrated.

Catalogue. Published by the New York Safety Steam Power Company, New York. 40 pages. Illustrated.

The Clayton Air Compressors. Published by the Clayton Air Compressor Works, of New York. 90 pages. Illustrated.

Various Catalogues. Published by the General Electric Company, Schenectady, N. Y.

Various Catalogues. Published by the Westinghouse Electric & Manufacturing Company, Pittsburgh, Pa.

In the Great Northwest

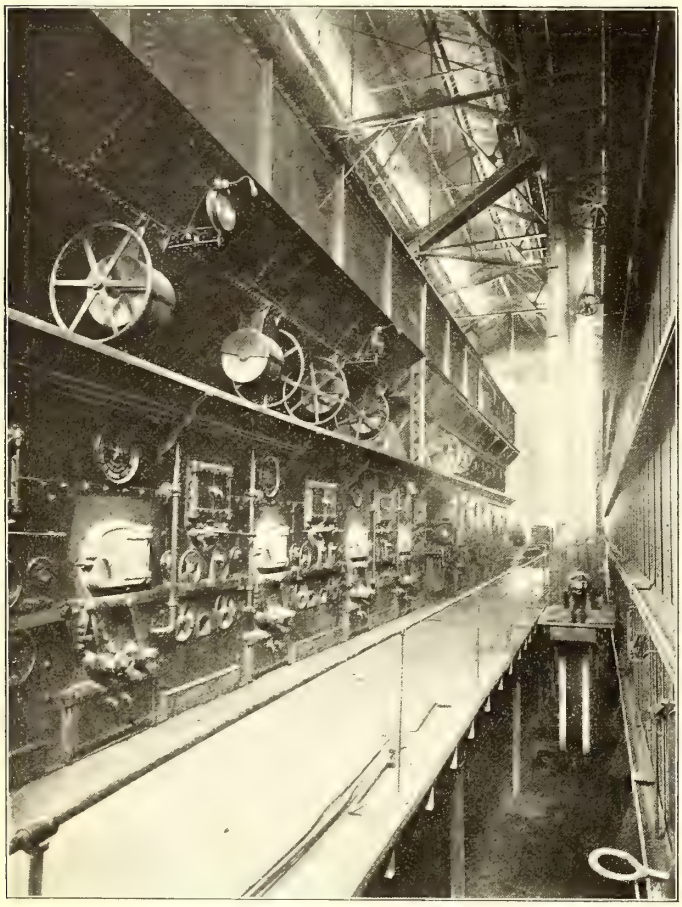
The Northern Pacific Railroad, whose headquarters are at St. Paul, Minn., has ready for circulation its annual publication describing the regions tributary to its system. Its book this year is known as "Wonderland '99," and contains a most entertaining story of the beauties of this region. Many of the principal resorts are mentioned in detail, and the best fishing and hunting points are charmingly described. The book is full of beautiful half-tone engravings, bringing out more forcibly than a mere description the wonderful scenery and resources of the "Great Northwest."

Street Railway Journal

VOL. XV. NEW YORK AND CHICAGO, JULY, 1899. No. 7.

SYSTEM OF THE UNITED TRACTION COMPANY, PITTSBURGH

The United Traction Company, of Pittsburgh is a typical example of the tendency developed during the last few years of combining in one corporation a large number of individual electric railway systems, and the history of the company exhibits in a striking way the advantages in the direction of economy derived by such consolidation. The company was chartered July 27, 1896, and has purchased all the rights and franchises of the Second Avenue Traction Company, the North Side Traction Company and the Pittsburgh, Allegheny & Manchester Traction Company. It includes all of the electric railway lines in the city of Allegheny, as well as the important Second Avenue line of Pittsburgh, which parallels the Monongahela River as far as McKeesport, with branches to East Pittsburgh and Wilmerding. Included in the Allegheny lines is the original system of the Federal Street & Pleasant Valley Railway, which possesses historic interest from the fact that it was one of the first, if not the first, of the electric conduit railways in America to be operated commercially. This line was changed to the trolley system, however, a number of years ago.

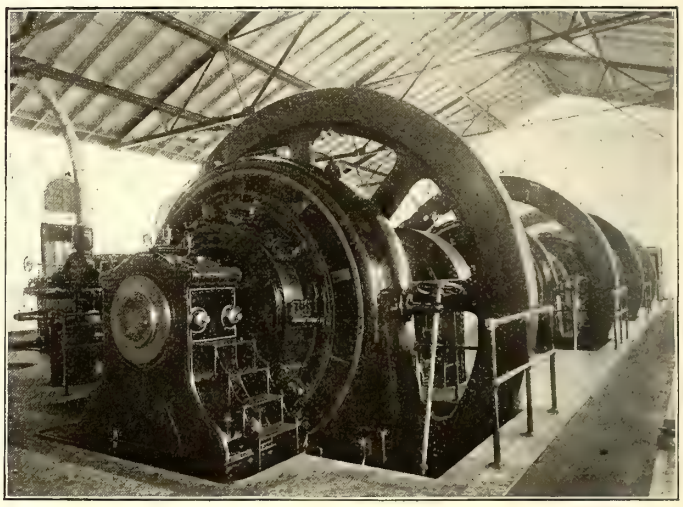


With the consolidation of the various lines the company found itself in the possession of a number of power houses, of which one only, that at Glenwood, which operated the Second Avenue system, was of modern construction. This fact, together with the extension of its lines east and west following the consolidation, made the subject of power generation and distribution an important question, and one requiring immediate consideration.

VIEW IN POWER STATION OF UNITED TRACTION COMPANY, PITTSBURGH

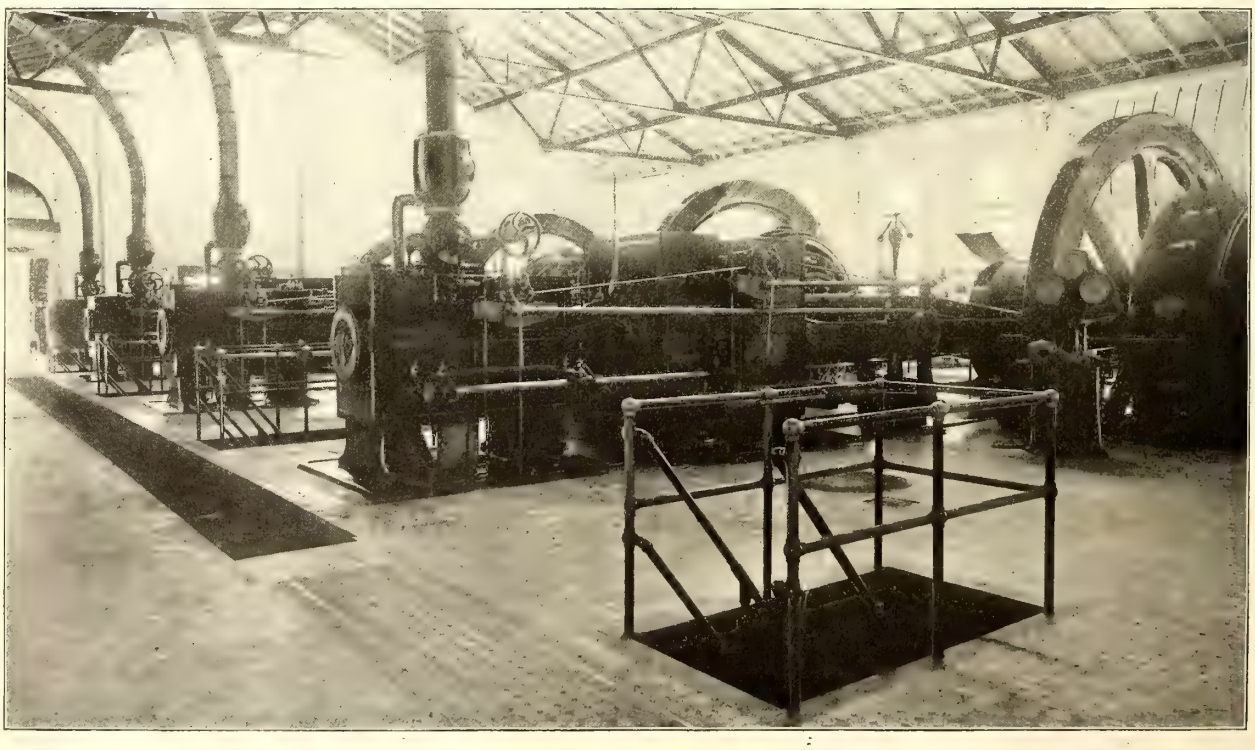
The system, as shown in the map on page 423, possesses a resemblance to an extended Y, with the Allegheny system near the base of the letter. It was finally decided to concentrate the generating power plant at two points, viz., at Glenwood, at the apex of the Y, and at Juniata Street, in Allegheny; and to have a third distributing point, *i. e.*, a storage battery booster station, at Dravosburg, near the McKeesport terminal, to be supplied with power from the Glenwood station. The need of three distributing points

was accentuated by the topography of the line, as steep grades are frequent. The steepest grade is on Pennsylvania Avenue, on the Manchester division, and averages



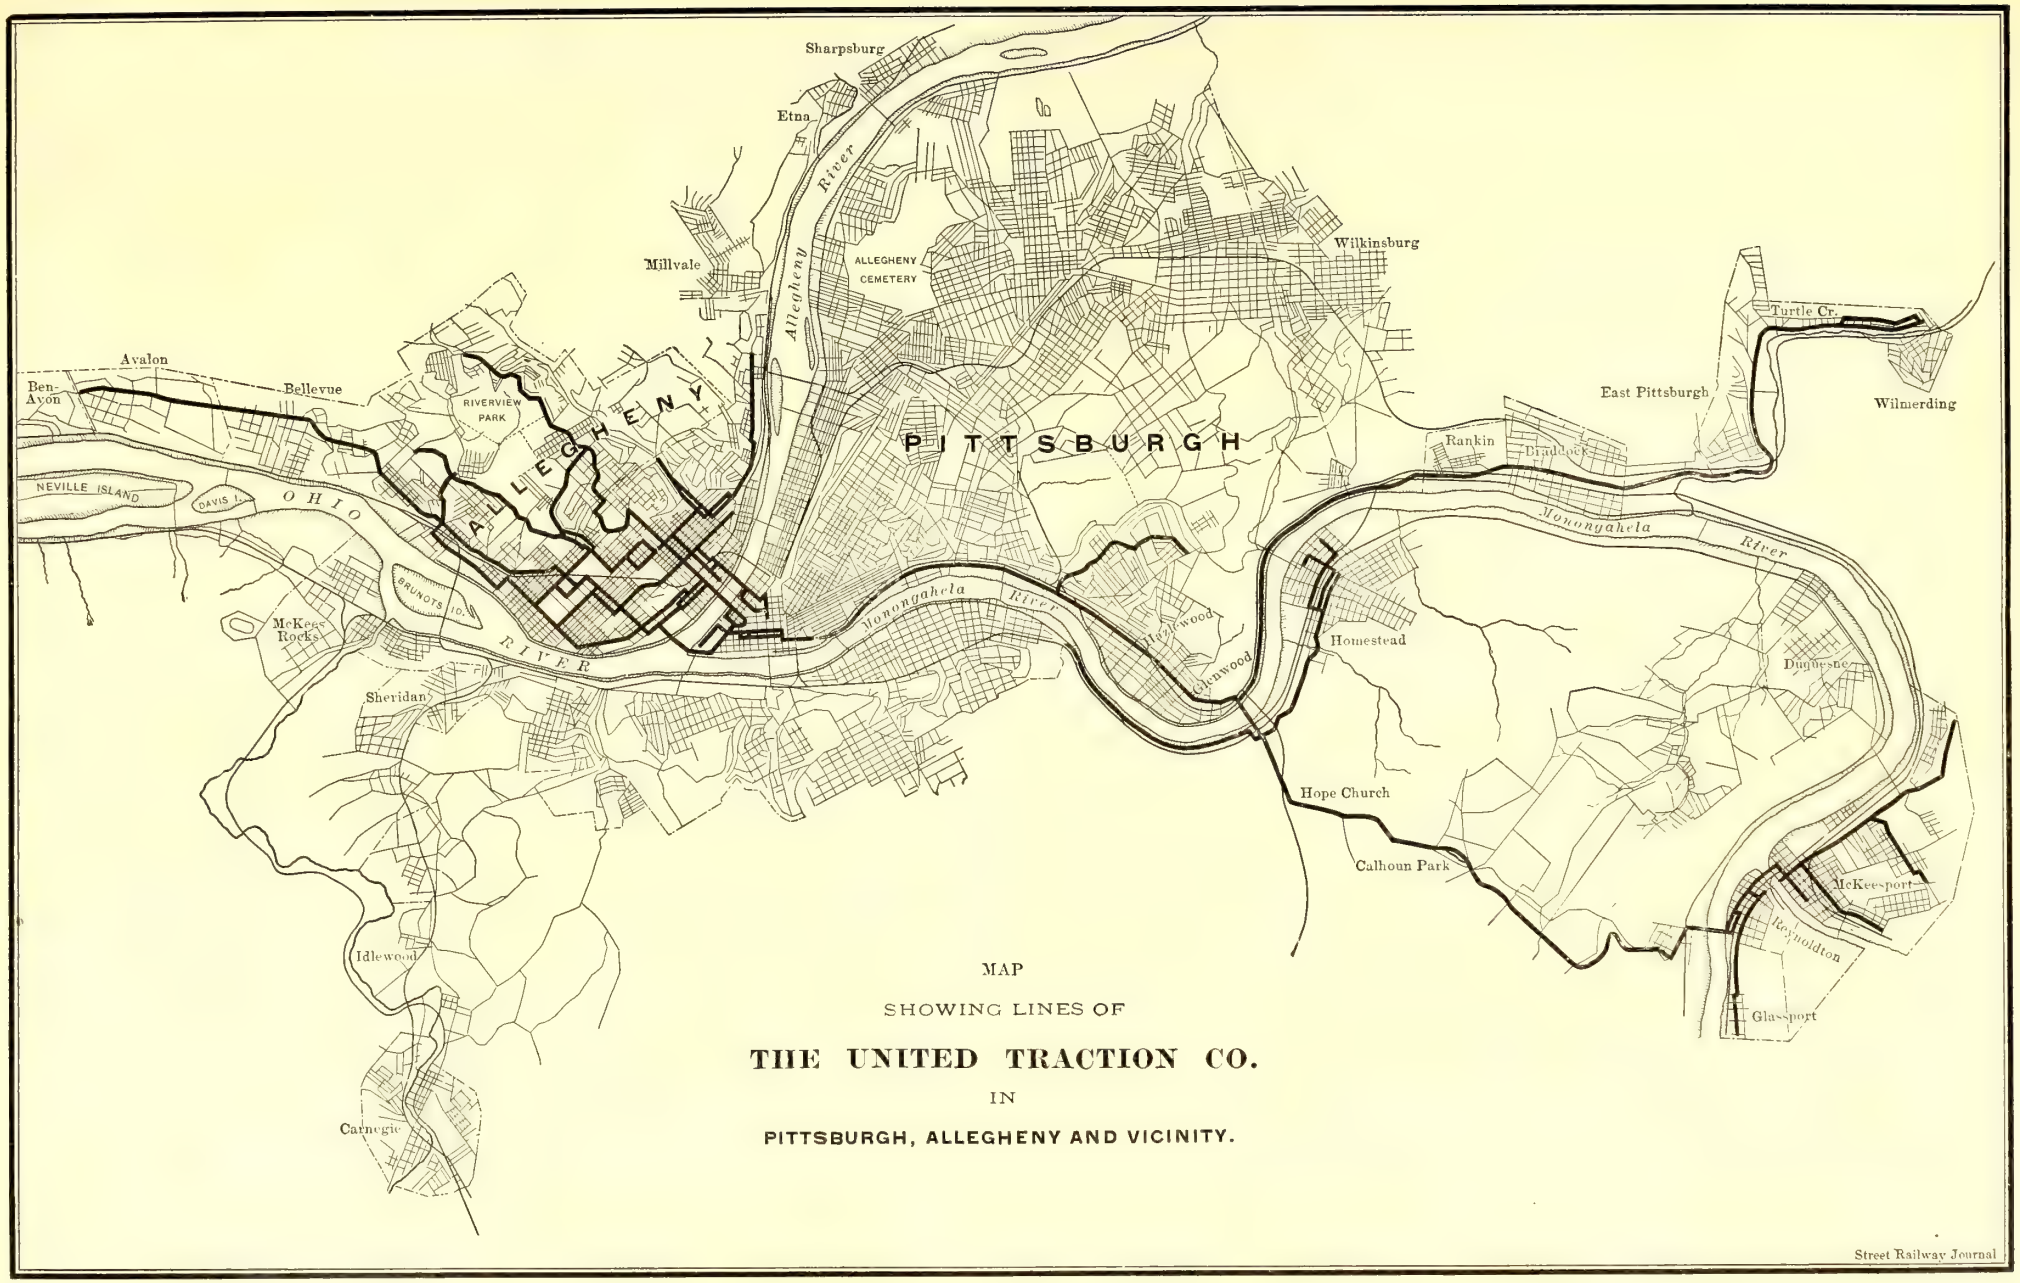
INTERIOR OF BOILER ROOM

13 per cent for a length of 900 ft. On the Dravosburg branch there is a grade of 6 per cent for 8000 ft., and on the Perrysville branch one of 11 per cent for 500 ft. In addition to these many other steep grades are encountered in ascending and descending the precipitous banks of the Allegheny, Monongahela and Ohio Rivers in the neighborhood of Pittsburgh.



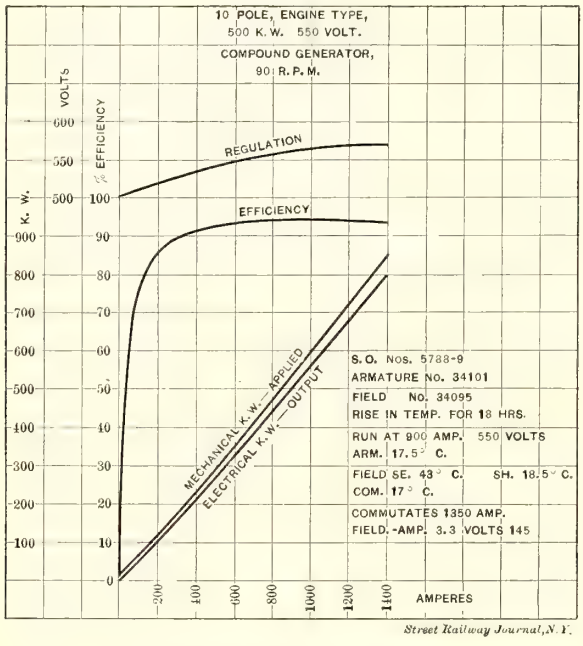
As now constituted the company possesses 117 miles of track, all electric, and 298 cars, of which 259 are motor cars and 39 trail cars.

In selecting a site for its new power station to take the place of the stations then existing in the western end of the system, the location of the existing station of the Pittsburgh, Allegheny & Manchester Traction Company, one of the constituent leased companies, was selected. This point seemed desirable in every way, as fuel could be delivered at the station doors from either of two railroads, or, at a slight expense for conveyor machinery, from the river barges, and as the station was near the "center of gravity" of the Allegheny section of the system. This station was



GENERATOR END OF ENGINE

on Juniata Street, Allegheny, and close to the banks of the Ohio River.



VIEW OF ENGINES

The old engine room gave abundant space for four direct connected units, although formerly all the available

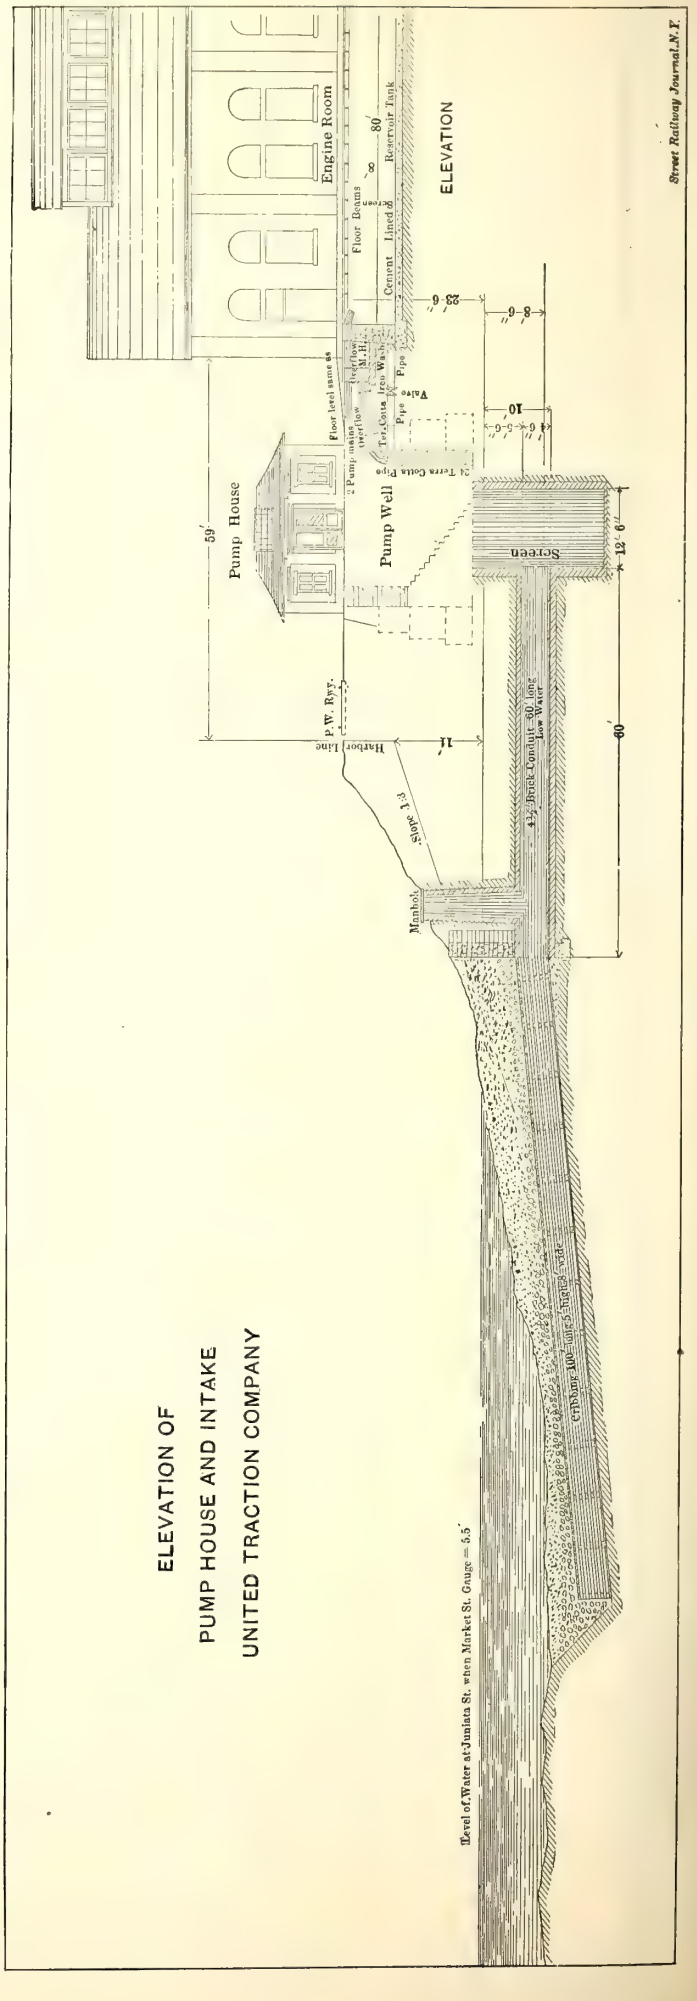
space had been occupied by half the same capacity in belted machinery. The boiler capacity, however, was inadequate, so that a new boiler house was added, adjoining and just west of the existing station. Reconstruction was commenced late in 1897, and, owing to the continuous demand for power, the new generating apparatus and boilers had been installed singly, so as not to interfere with the continuous operation of the plant. Gradually all of the old machinery was removed, and the existing station now represents a harmonious arrangement, and one fully up to date as regards modern methods of electric engineering. There is not a piece of machinery now in the station that was there when the installation of the new machinery began. The difficulty of the changes can be appreciated when it is stated that current to the former capacity of the plant was furnished continuously for the operation of the road during the progress of the installation.

One of the chief considerations which had to be borne in mind by the designing engineers was the changes in water level produced by the rise and fall of the Ohio River at different periods. The difference in the water level between



GENERATOR DATA CURVES

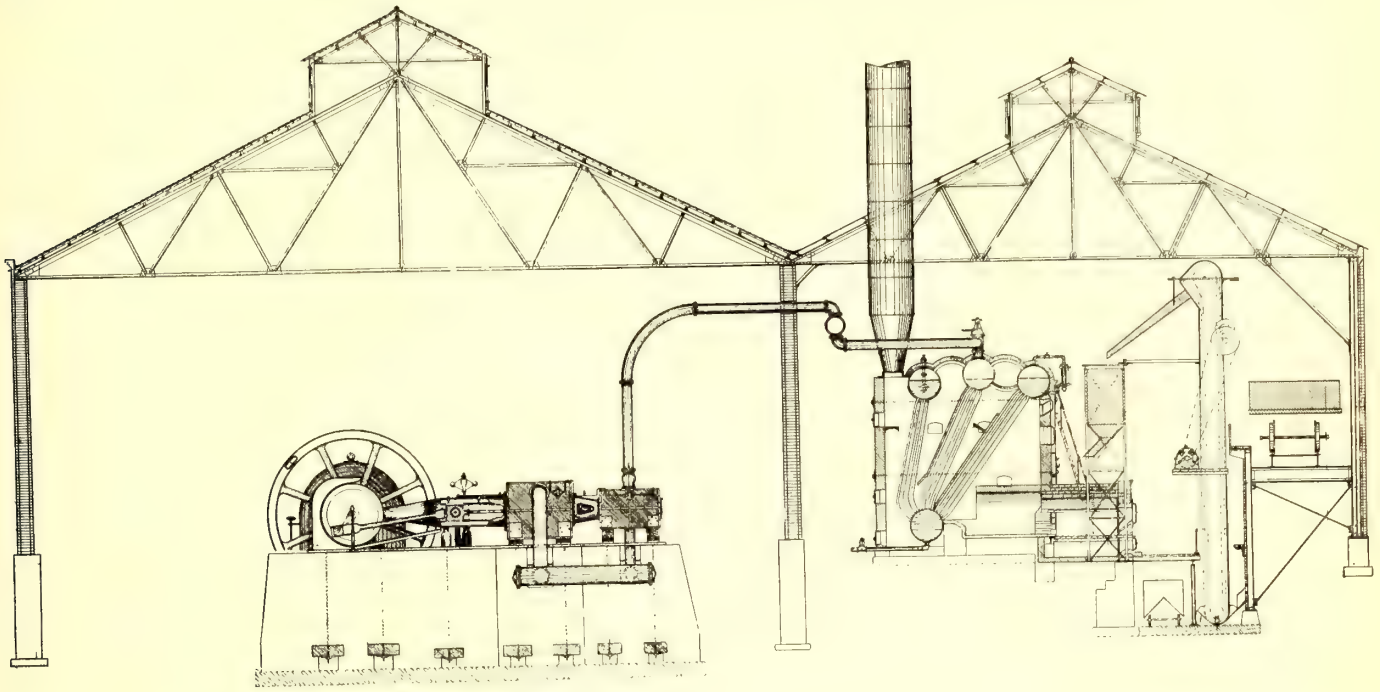
high and low water mark amounts to about 30 ft. The extent of this rise and fall can be seen graphically from an inspection of the diagram on this page, in which the low water mark is given, while the high water mark is close to the tracks of the P. & W. Ry., or within a few feet of the engine room floor.

The rise and fall of the river level necessarily affected also the location of the condenser pumps, which, as will be seen by the diagram already referred to, are located in a well. From this point they lift the water 20 ft. above the lowest water level, and then force it 8 ft., discharging it into a cistern, from which point it is pumped to the condensers.

The same diagram also shows the construction of the crib, which was an important feature in the installation of the plant, as the feed water is also taken from the river. It was found that the river water itself was too muddy for use directly in the boiler, but if filtered somewhat it was amply good for the purpose. The crib is made up of hemlock plank laid 2 ins. apart, with a transverse plank every 8 ft., and measures 100 ft. long x 8 ft. wide x 5 ft. high. The top is from 3 ft. to 5 ft. below the natural bed of the river. It was then covered, first with broken stones and

ELEVATION OF
PUMP HOUSE AND INTAKE
UNITED TRACTION COMPANY

brickbats, and afterwards with gravel and sand, which provided an excellent filtering material.



The engine room illustrated on page 421 presents a light and attractive appearance from the fact that the walls are painted white and are furnished at their bases with a dado of white glazed tiles with green stripes. The floor is laid with white unglazed tiles.

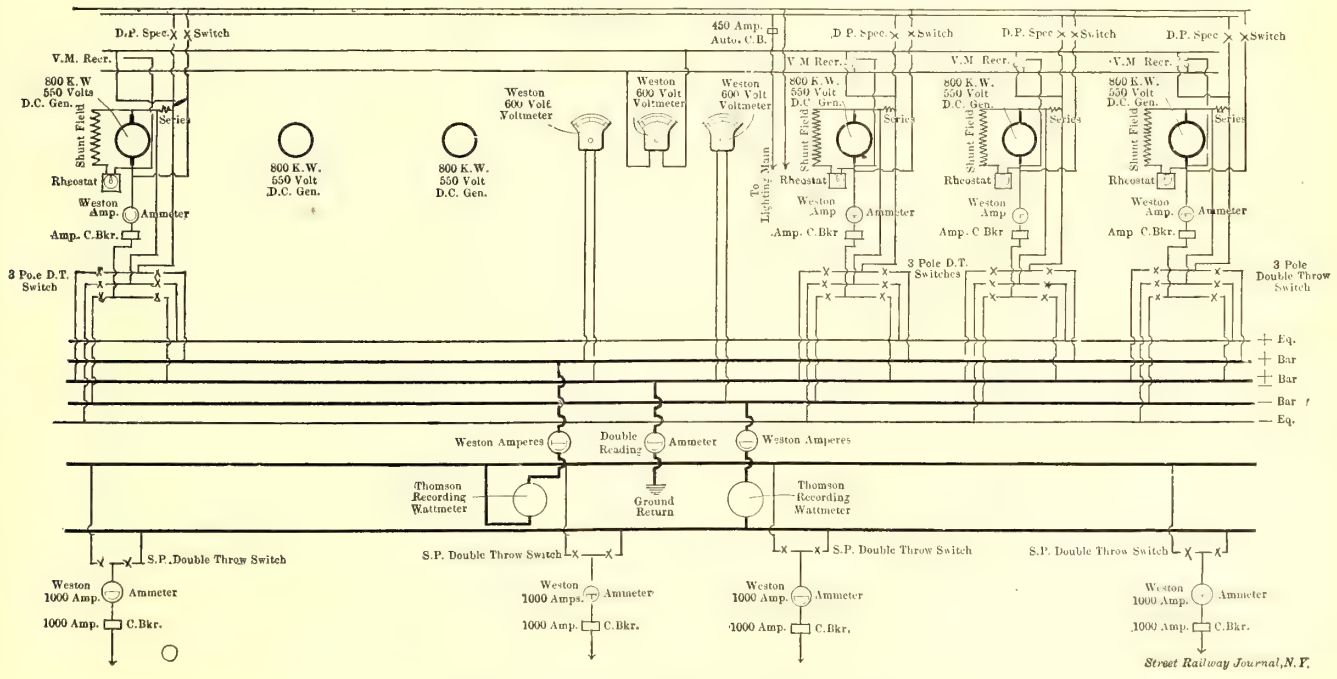
The engine room contains four tandem compound Green engines, the cylinders of which measure 28 ins. and 38 ins. x 48 ins. stroke. They are operated at 100 r.p.m., and are rated at 750 h.p. nominal, with capacity for 50 per cent overload. The flywheels weigh 60,000 lbs., and the steam pressure used is 125 lbs. These engines have shown on test an economy of 14 lbs. of water per h.p. hour. They were supplied by the Providence Steam Engine Company, of Providence, R. I.

Each engine has its own pump and separate jet condenser, which is of the Laidlaw-Dun-Gordon type. These condensers are located in the basement, and obtain their water supply from the crib system already mentioned.

The generators were built by the Westinghouse Electric & Manufacturing Company, are of 500-kw. capacity each, but are guaranteed to run up to 625 kw. continuously, with no part rising in temperature more than 40 degs. C. above the surrounding air. A load of 750 kw. for two hours, or of 875 kw. for ten minutes, is permitted under a guarantee that there shall be no injurious sparking or heating, and no necessity for shifting the brushes from the no load position. If the armature shall be placed 1-16 in. out of center there shall be no vibration, heating or sparking. All of these guarantees were easily fulfilled in a recent test.

The generators are of the well-known Westinghouse "engine type" construction; the field has ten poles, with

CROSS SECTION OF POWER STATION



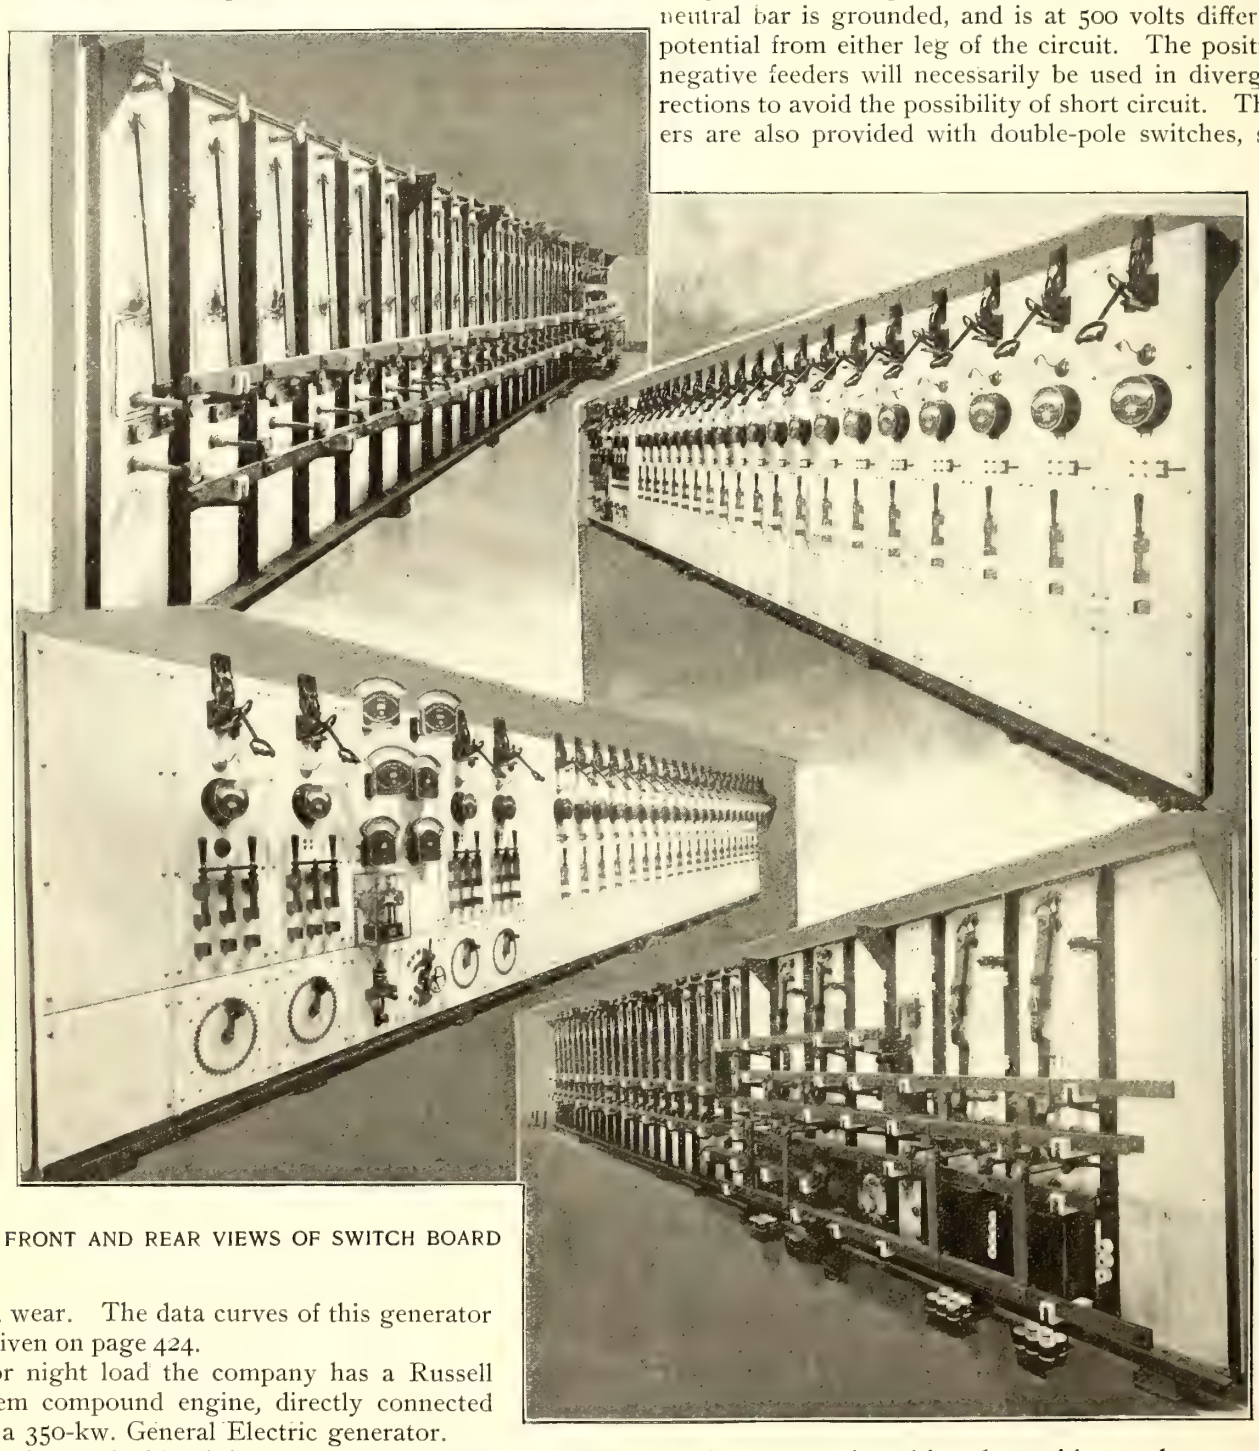


DIAGRAM OF SWITCH BOARD CONNECTIONS

series and shunt coils, wound and insulated separately, giving excellent ventilation. The pole pieces are of laminated steel, cast into a massive cast iron yoke. The field frame is split vertically and rests on a wedge-shaped bed plate, by means of which it can be raised or lowered 1 in. The armature is of the ironclad type, and has no bands, the coils being held in place by fibre wedges driven into notches near the top of the slots. The armature winding is of copper bars bent to proper shape, and then insulated. The commutator has ample surface, and the bars will stand 2 ins. wear. The data curves of this generator are given on page 424.

FRONT AND REAR VIEWS OF SWITCH BOARD

For night load the company has a Russell tandem compound engine, directly connected with a 350-kw. General Electric generator.

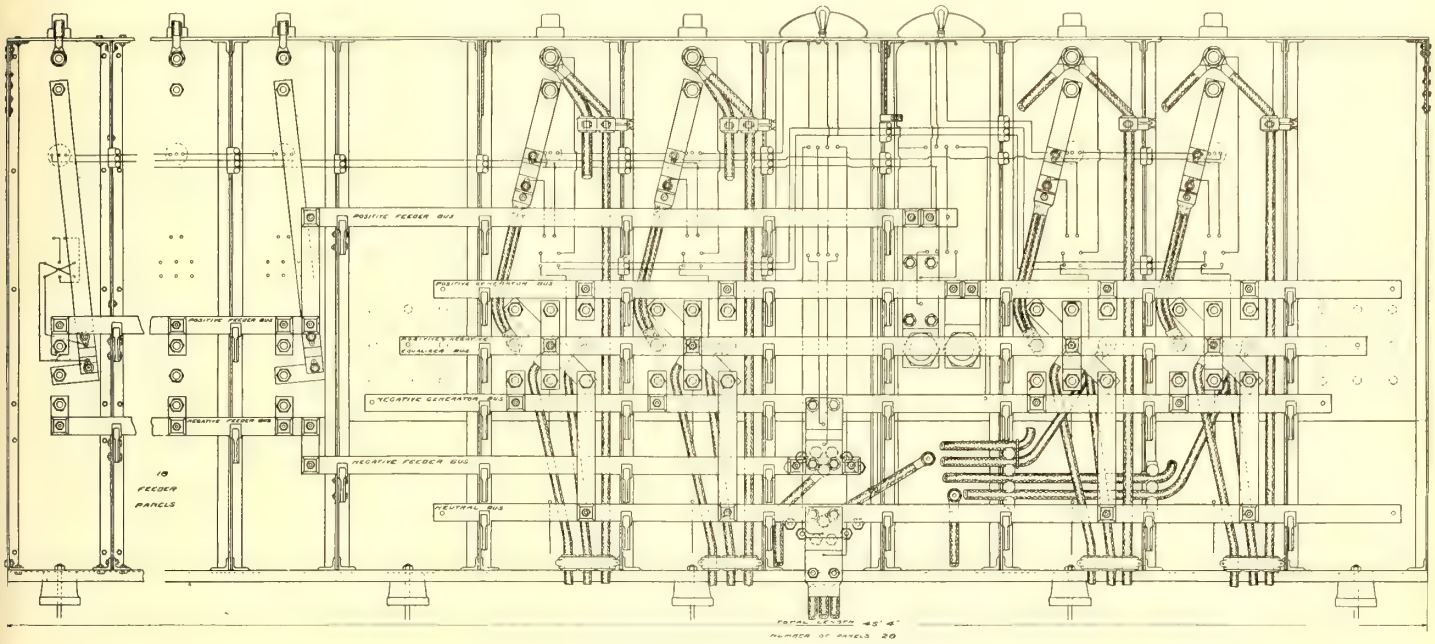
On the south side of the station is a switchboard, which for a number of reasons possesses unusual interest. One of these is that it has the largest three-wire street railway panel switchboard in the world. While the company has not yet commenced the operation of its lines on the three-wire system, and has no immediate plans for changing to this system at any stated date, the advantages of that method of operation were considered so great as to warrant the installation of the necessary apparatus on the switchboard for making the change at any time in the future. A general diagram of the connections is given on page 425, and the actual location of the apparatus and equipment on each panel on the opposite page.

By means of double-pole generator switches any generator can be connected to either side of the three-wire system, or all may be used on one side of the system, in which case the station would operate as a two-wire plant. When run three-wire, the difference in potential between the positive and negative bus bars is 1100 volts, while the neutral bar is grounded, and is at 500 volts difference of potential from either leg of the circuit. The positive and negative feeders will necessarily be used in diverging directions to avoid the possibility of short circuit. The feeders are also provided with double-pole switches, so they can be connected to either the positive or the negative bus bars, which will facilitate the balancing of the two sides of the three-wire system.

The construction of the switchboard is the standard Westinghouse No. 5 type, the slabs being white Italian marble and having the standard angle and channel iron frame. There are four generator panels, one double-load panel and twenty feeder panels, with space for two more generator panels.

The generator panels are 1200 amps. capacity each, and each is supplied with a standard rheostat panel below. The double-load panel has a normal capacity of 10,000 amps. at 1100 volts. The necessary Weston ammeters are supplied for indicating the station load in each of the three circuits, and Weston voltmeters are provided for reading the generators when changing the light circuit from one machine to the other.

The feeder panels are 900 amps. capacity each, and each ammeter is fitted with a double-throw switch to reverse the ammeter leads when changing the feeders from the positive to the negative bus bars, or vice versa, to prevent



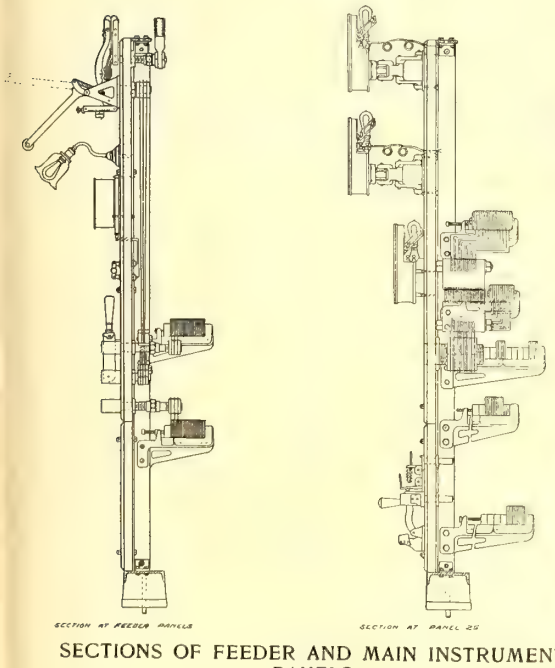


DIAGRAM OF SWITCH BOARD CONNECTIONS

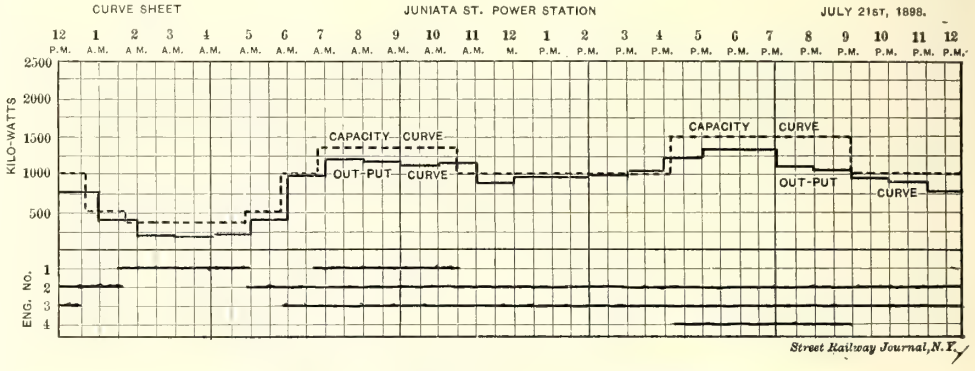
the bus bar potential when the machines are run in multiple or series. The voltmeters are mounted on swinging brackets, so that they may be readily seen from the ends of the switchboard; in addition a Thomson recording wattmeter of 10,000 amps. capacity is provided for use when running as a two-wire system.

The lighting switch situated beneath the load panel is

reversing the current in the ammeter. On each feeder panel is a 1000-amp. ammeter, a single-pole double-throw switch, and an 800-amp. Westinghouse circuit breaker. There is also a small double-pole double-throw switch for reversing the ammeter connections when the feeder is thrown from one side of the three-wire system to the other. This switch can also be used for opening the ammeter circuit when the engineers desire to put a temporary overload on the feeder for burning out a short circuiting wire, or for any other purpose.

SECTIONS OF FEEDER AND MAIN INSTRUMENT PANELS



PAYMASTER'S CAR

so connected to the generators that the light circuit may be taken from any machine in the station and the lights will not be affected by the opening of the main circuit breakers. The small circuit breaker beside this switch is directly in the main lighting circuit. The switch is special, and made so as to interlock and prevent short circuiting

The circuit breakers are of the Westinghouse "brush" type, and are placed at the top of the board. This type of breaker is one of the latest productions of the Westinghouse Electric & Manufacturing Company. The switches are made entirely of copper, are of the "washer" type, and are all double-throw, as noted.

The large capacity of this board, together with its complicated set of connections, made it difficult to place the necessary copper conductors on the rear, and the engraving of the back of the board shows the construction which was used. In order to get the necessary cables to the instrument studs on the switchboard the rheostats were placed separately, being connected to their face plates by conductors carried in a hose.

The bus bars are of bare copper, being made up of individual bars of 3 ins. x $\frac{1}{8}$ in. section, with $\frac{1}{8}$ in. space between for ventilation. The positive, negative and neutral bus bars each consist of twenty-three of these bars, and each total bus bar is of sufficient carrying capacity for six 500-kw. generators operating on the same side of the three-wire system. As the bus bars are laminated and tapered, the maximum carrying capacity for the least amount of copper is obtained.

FORM FOR KEEPING STATION RECORDS

The connections between the generators and switchboard consist of two 650,000 c.m. rubber-covered cables in parallel, for positive, negative and equalizer. These cables are supported by special porcelain insulators to the I beams forming the ceiling of the 10-ft. basement and the floor of the engine room.

The switchboard itself rests on large wooden blocks, which are carried on 10-in. I beams, which in turn rest on

INTERIOR PAYMASTER'S CAR

brick piers built up from the basement floor. The latter is of concrete.

The boiler room contains four Stirling batteries of 400 h.p. each, and one battery of Babcock-Wilcox boilers. A special stack is provided for each battery, and each boiler is equipped with Murphy stokers.

The freight cars carrying the coal are run on a trestle into the boiler room, and discharge their loads into a large iron bin of thirty carloads capacity, in front of the boilers. In front of this bin is a track, on which runs a coal conveyor or elevator consisting of an endless chain of buckets, driven by an old Sprague No. 6 motor, which has been changed over to shunt winding. These buckets can be filled at any point along the bin, and raise the coal to a height where it can be shot down into the hoppers above the Murphy stoker with which each boiler is equipped. The ashes are discharged from the boilers into hoppers located in the basement, and are taken out by a small car drawn by a cable operated by an electric motor situated just outside of the boiler room proper. A National feed water heater completes the equipment of the boiler room.

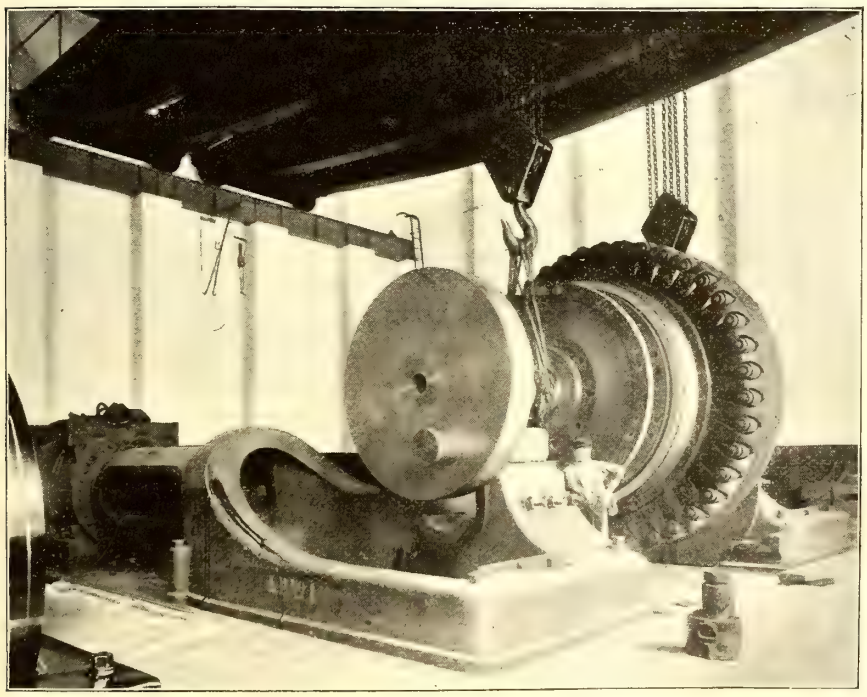
For feed water the company is using the overflow from the condensers, and although there is naturally a slight admixture in it of oil from the cylinders, no trouble has been experienced with scales in the boiler tubes. The advantage of using this overflow is, of course, that water of a temperature of from 95 to 100 degs. is available. The heater is supplied with exhaust steam from the auxiliaries, and the feed water is forced into the boilers at a temperature of 212 degs.

A method of keeping engine and output records maintained at this station is illustrated in the accompanying form. An ordinary sheet of plotting paper is used, on the upper part of which is plotted the output curve, shown by the solid line, and below the hours during which the different engines are run. From the latter the capacity curve, shown by the dotted line, is drawn, superimposed on the output curve. These daily sheets show at a glance whether too many machines are being run for the work to be performed.

The Glenwood station, from which the power for the eastern end of the line is taken, was described in the Street Railway Journal for August, 1895. It contains two compound Russell engines, each coupled to a 500-kw. Westinghouse generator, and two Green engines of the same type as in the Juniata Street station, directly connected to 500-kw. Westinghouse generators. The company will also install two 800-kw. generators at this station in the future, but the contract for these has not yet been awarded. The station also contains two boosters; one for supplying the Wilmerding line, and the other for supplying the current to the storage battery station at Dravosburg. This battery contains 424 cells, has been in use about a year, and it is found in practice most satisfactory. Since its original installation its capacity has been doubled by adding the necessary number of plates to each cell. By its use the company has been enabled to shut down an auxiliary power station which it formerly used at McKeesport.

In its track construction the company uses a 90-lb. girder rail and Bryan bonds are used throughout. For its overhead line the company used a 7 in.-6 in.-5 in. tubular pole, with General Electric line material.

The standard car has a 20-ft. body, vestibuled, and it is mounted on a single Lord Baltimore truck, which is used

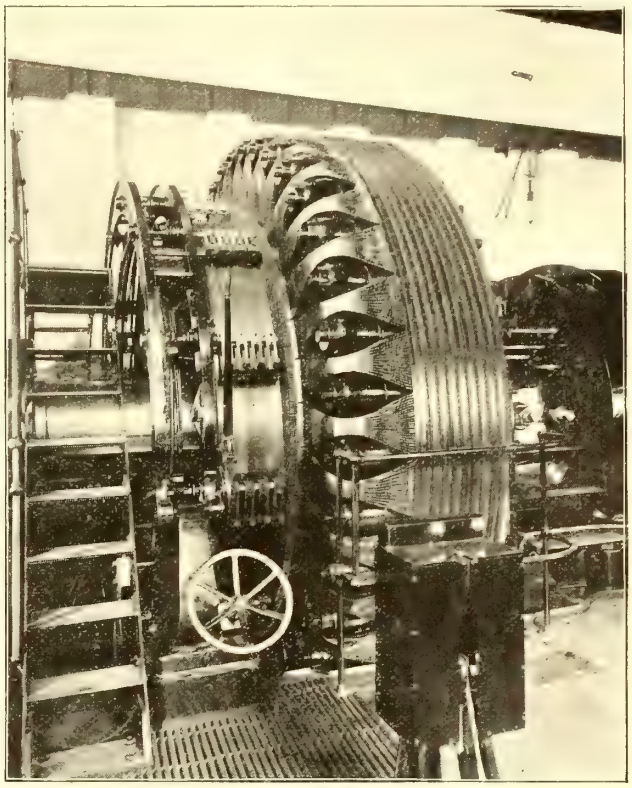


as a standard on this line, and is giving good satisfaction. The company has only one double-truck car equipment. The Sterling register is used throughout, and the gongs are carried on the hood, instead of under the platform. This is done because it is thought the sound is louder and clearer than when located under the platform. The gongs are rung by means of a strap which the motorman pulls by the same hand with which he manipulates the controller. All cars are equipped with illuminated signs on the hood.

A somewhat novel type of car is illustrated on page 427. This is a car used by the paymaster, and is fitted at one end with a safe and closed vestibule, in which the paymaster sits. The employees are paid off three times a month, and as they pass through the car they are given their envelopes by the paymaster.

The officers of the United Traction Company are: President, James D. Callery; secretary, J. H. Callahan; treasurer, John W. Taylor; superintendent and chief engineer, John Murphy. The mechanical engineer of the company is S. L. Tone, and constructing electrical engineer is P. N. Jones, of the Westinghouse Company.

Additional Equipment for Western Avenue Power Station of the West Chicago Street Railway Company



The accompanying illustration shows the armature and shaft of a 1500-kw. Siemens & Halske generator in the process of being installed in the Western Avenue power station of the West Chicago Street Railway Company. This is an additional unit to the five that compose the original equipment of the station. This armature has a specially designed commutator, as shown in the illustration. The armature is 14 ft. outside diameter, and is designed to run at 75 r.p.m. The shaft is hollow and 23 ft. 3 ins. in length, and is composed of fluid compressed steel made

PLACING ARMATURE AND SHAFT IN POSITION

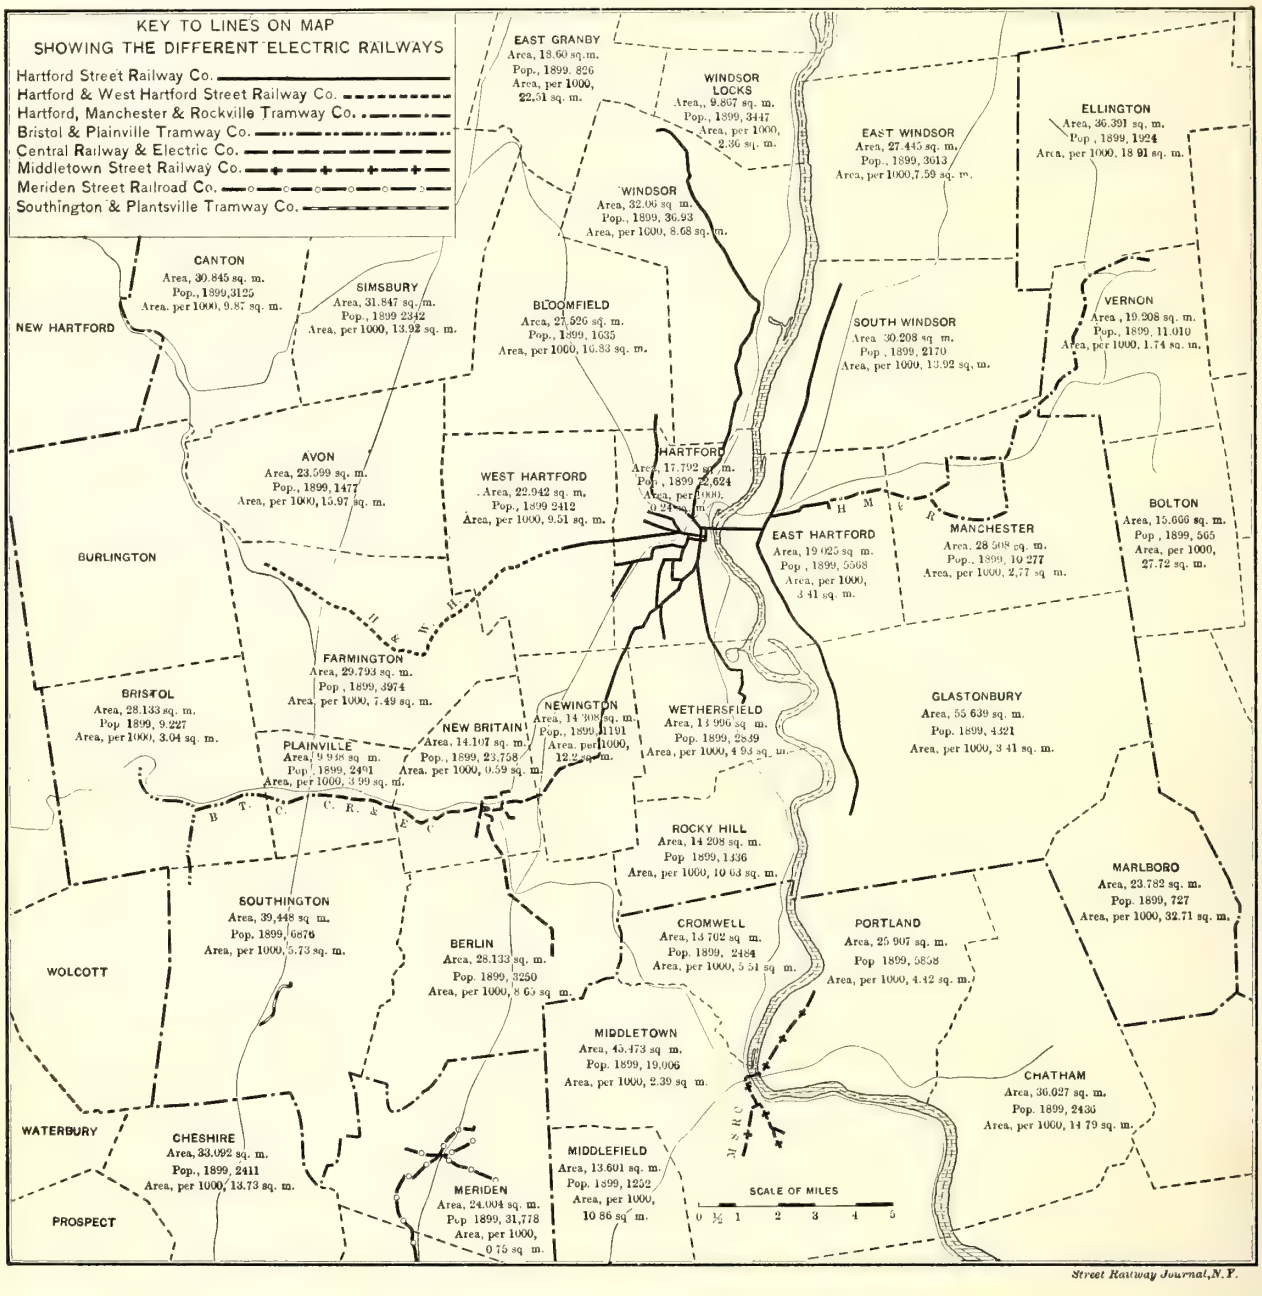
by the Bethlehem Iron Works. It is 28 ins. in diameter at the wheel, while the bearings are 22 ins. in diameter and 46 ins. long. Each of the crank pins is 12 ins. x 12 ins.

The engine to which the generator is coupled is a cross-compound non-condensing machine, with cylinders 34 ins. x 54 ins. x 60 ins., and is rated at 2000 h.p. The flywheel is 25 ft. in diameter, and weighs 80 tons. The steam and exhaust valves are operated by separate eccentrics, while the valves are of the double-port type. The engine was

MODIFIED ARMATURE

designed and built by the Pennsylvania Iron Works Company.

When completed the total engine power capacity of the station will be 12,000 h.p. It is interesting to note in this connection that three of the original generators, which were also manufactured by the Siemens & Halske Company, have been redesigned, with the commutator placed on the side, and of smaller diameter than the armature. It will be remembered that in the first installation of the generators in this station the commutator bars were placed in the periphery of the armature, but owing to the high speed some difficulty was experienced in maintaining the bars in position. The remodeling consisted of introducing connections, thus reducing the diameter of the commutator. The equipment is now working in a highly satisfactory manner, although it has been loaded greatly above the rated capacity of the machines ever since it has been in operation. Current is not only supplied for operating the cars of the West Chicago system, but for operating those on the Lake Street Elevated Road. The voltage is 550, and the two systems are operated from the same bus bar.



The steam equipment is being improved by the installation of automatic stokers. The boilers are of the Stirling type, and two of these, which are rated at 400 h.p. each, are each being provided with two American stokers, which are required to burn 1000 lbs. of Illinois coal per hour. One of the other boilers is being equipped with a stoker of a chain grate type, installed by the Greene Engineering Company, of Chicago. These two types of stokers are being installed

for the purpose of making a competitive test, with the view of deciding which type shall be employed for equipping the remaining boilers.

Electric Railways in Central Connecticut

Although possessing no city of 100,000 population, an electric railway system of considerable extent exists in the central part of Connecticut surrounding the cities of Hartford, New Britain, Middletown and Meriden. These systems are controlled by eight separate corporations, of which several form connecting links, while others are operated entirely independently of the others. The region through which these railways run is dotted with small manufacturing communities, and the inhabitants are, as a whole, quite prosperous, so that a study of the earning capacity of these railways per mile of track is of interest.

The accompanying engraving shows the location and extent of the different systems, with area of the several townships and area in square miles per thousand inhabitants. The earnings for the several systems, as given in the table below, are taken from the last report of the Railroad Commissioners of the State of Connecticut, and, owing to a change in the fiscal year of these commissioners, are given for nine months only. The final two columns give the proportionate increase for twelve months, derived from adding one-third to the nine-months' figures, but in reality the earnings would be somewhat in excess of this, as the earnings reported to the Railroad Commissioners cover six winter months and three summer months. As will be seen, the earnings per mile vary from $2,200 to $8,300 per mile, the maximum figure being practically the same in the case of the Hartford Street Railway Company and the Central Railway & Electric Company:

EARNINGS ENDING JUNE 30, 1898.

	Miles.	Earnings, 9 Mos.	Earnings per Mile Track, 9 Mos.	Earnings, 12 Mos.	Earnings per Mile, 12 Mos.
Middletown	7.9	18,403	2,329	24,537	3,106
Meriden	17.5	72,177	4,124	96,236	5, 99
Central Ry. and Electric	18.6	116,193	6,247	154,924	8,329
Hartford Street	70.3	438,069	6,230	584,092	8,309

Bristol and Plainville	7.9	44,384	5,618	59,179	7,491

* For 6 months.

Interurban Railway Between Wilmington and Chester

The connecting link between the electric railway systems of Wilmington, Del., and Chester, Pa., was put in operation March 22, and is now carrying a large number of passengers. This completes the through line of electric roads extending from Darby from just outside of Philadelphia, to Wilmington, all of which is under one management; the operating official is R. F. Fox, who is general manager of both the Wilmington City Railway and the Chester Traction Companies. Through cars are now run from the P., W. & B. R. R. station in Wilmington through Chester to Darby, a distance of $13\frac{1}{2}$ miles; at Darby the cars connect with the Darby division of the Union Traction Company of Philadelphia. The running time between these terminals is one hour. The cars have to conform to the running schedule of the city cars while within the limits of Wilmington and Chester, but between cities often run at a speed of 20 miles an hour.

The line between Chester and Darby, which was put in operation several years ago, has developed the traffic on the Chester Traction system enormously, as shown by

STANDARD CAR

LOADING BALLAST CAR AT QUARRY

STRAIGHT TRACK NEAR CLAYMOND

CATTLE GUARD

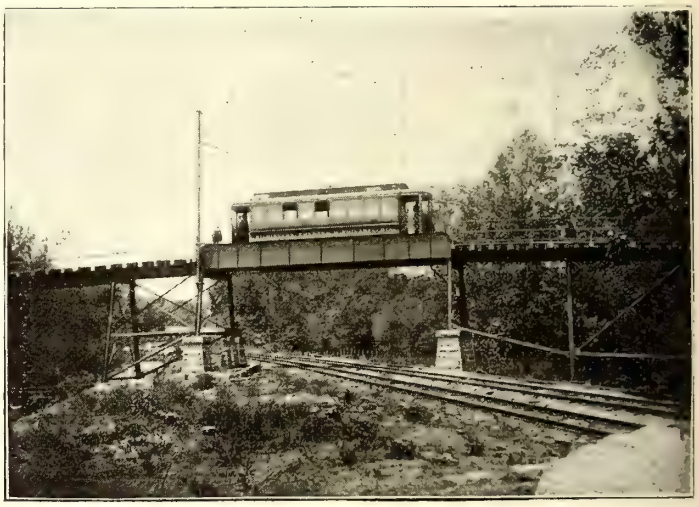
ON THE TOP OF THE RIDGE

CONSTRUCTION NEAR WILMINGTON

figures published in the Street Railway Journal for February, 1898, in which a table was given showing the average rides per capita per year for a number of towns, varying in population from 20,000 to 40,000. In this table it is shown that on the Chester lines the average rides per capita was 222; while in nine isolated cities of about the same population the rides per capita did not average much over 50. Statistics showing the increase in traffic, owing to the opening of the through line to Wilmington, are not yet available, but present indications point to a large increase due to the through traffic between the cities.

The line extends for a considerable distance on the top of a ridge which lies between Wilmington and Chester, so that the ride is a most picturesque one, with attractive views on each side, and one on which the pleasure traffic ought to be considerable. After leaving the lines of the Wilmington City Railway it extends over a private right-of-way about four miles in length to Claymond; then, for about 3800 ft. the line is built along the side of the turnpike, and then branches off into a private right-of-way for a distance of 2 miles until the Chester city line is reached.

The track is laid with 70-lb. A. S. C. E. rails in 60-ft. lengths. Churchill ties are used, and the rails are double bonded with No. 0000 protected bonds, supplied by Mayer & Englund. The ties, which are of oak and chestnut in equal proportions, measure 7 ins. x 6 ins. x 7 ft. 6 ins., and are laid 2 ft. centers. The track is ballasted with broken stone throughout, to a depth of from 3 ins. to 4 ins. below the ties, and in some places the ballast is considerably deeper. The company owns its own quarry and crusher, and all ballasting was done from a special car into which the broken stone is loaded at the quarry and from which it is distributed along the track.

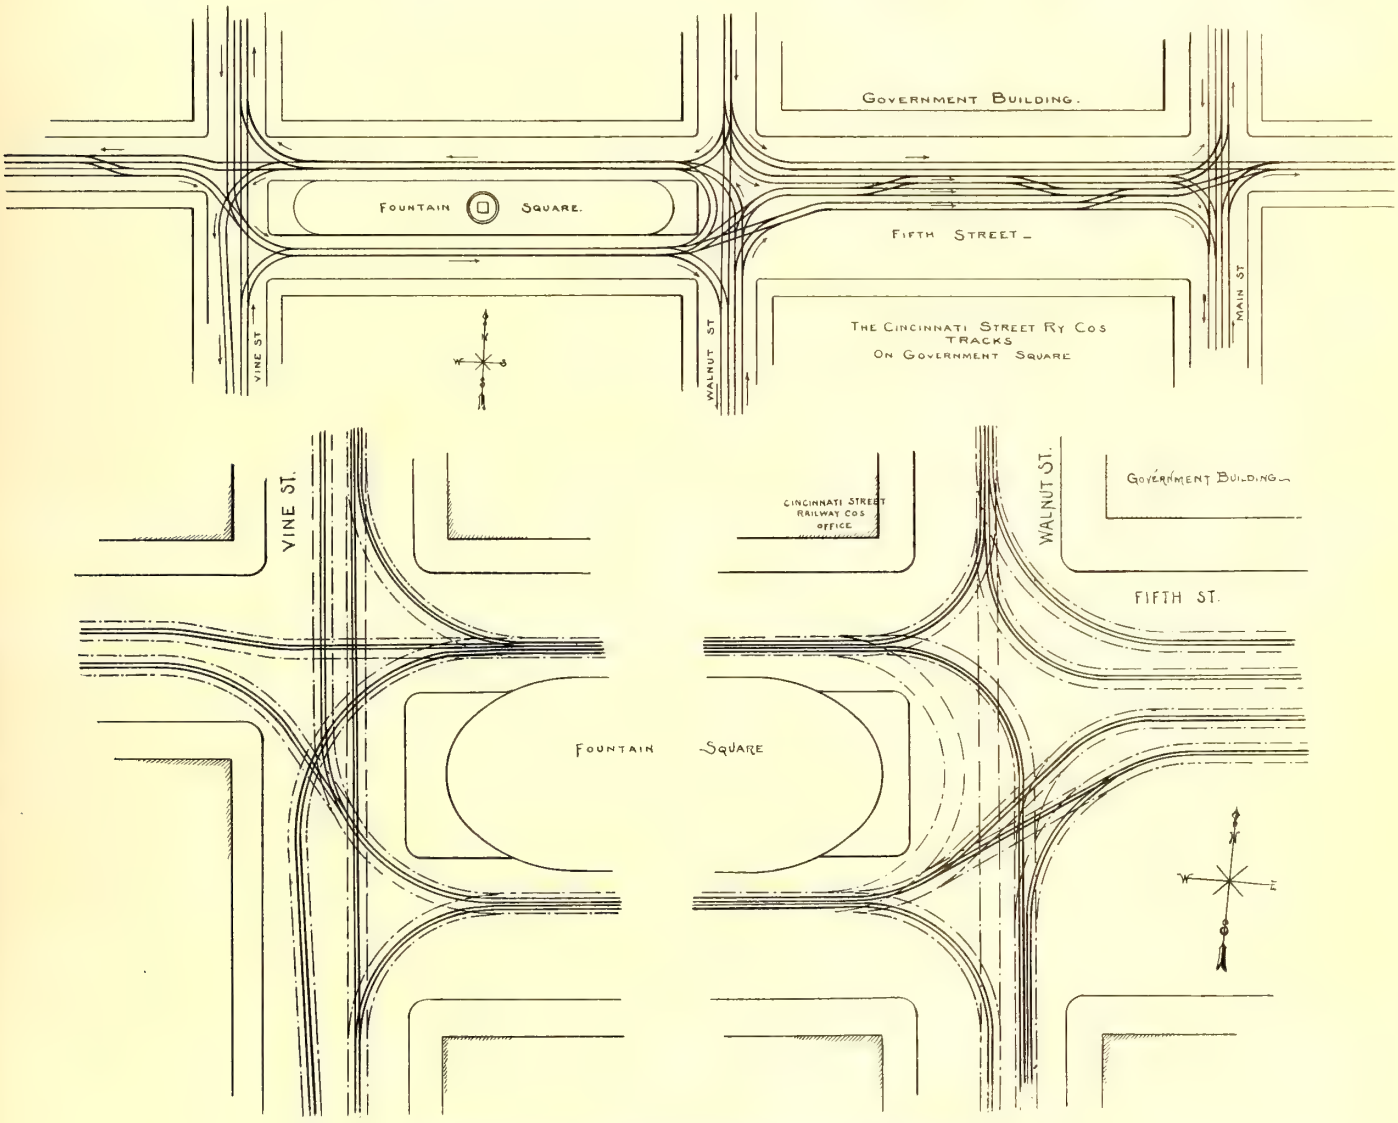


The grades are frequent, and on the section between Wilmington and Chester are in some places as high as 6 per cent. This portion of line is 10.3 miles long, of which .65 of a mile are in turnouts. Wharton frogs and switches are used throughout.

The poles are of chestnut, not less than 7 ins. in diameter at the top and 12 ins. at the butt. They are 30 ft. long, shaved and pointed, and set 100 ft. apart. The overhead line is partly of flexible bracket construction and partly span work. The H. W. Johns line material was used throughout. The trolley wire is a No. 00, supplied by Roebling.

BRIDGES AND VIADUCTS ON CHESTER-WILMINGTON INTERURBAN RAILWAY

The cars were built by Jackson & Sharp, and are extremely tasteful in design and finish. They are mounted on Brill maximum traction trucks, with 4-in. axles and 33-in. wheels, and are equipped with Westinghouse No. 38 B motors, with K-10 controllers. The company is also having six open twelve-bench cars built by the St. Louis Car Company, the equipment of which will be similar to that of the closed cars already mentioned.



A half-hour service is conducted between Wilmington and Chester, except on Saturdays, when the cars are run every 15 minutes. Between Chester and Darby they are run every 17½ minutes. The fare between Wilmington and Chester is 20 cents; that of the railroad connecting the two cities is 33 cents. The line is supplied with power from the existing stations at Wilmington and Chester.

Track Construction of the Cincinnati Street Railway Company

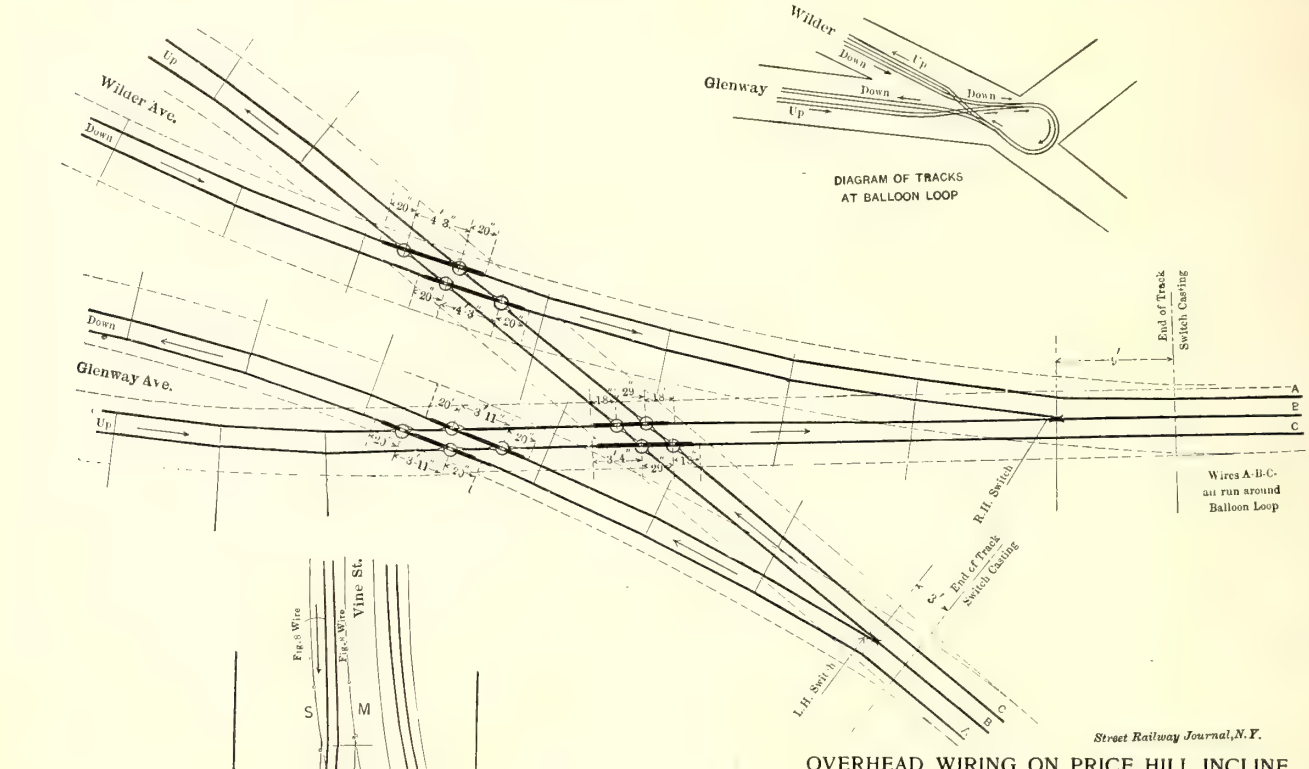
In July, 1894, a description of the track construction of the Cincinnati Street Railway Company appeared in these columns, and the standard then employed in track work was described as follows:

"In the process of construction the pavement is removed and the surface excavated to a depth of 20 ins. The foundation is then rolled with a steam roller weighing 250 lbs. per lineal inch of surface measure. The oak ties, 6 ins. x 7 ins. x 8 ft., with joint ties, 6 ins. x 12 ins., are then placed with 2 ft. 6 in. centers. The rails are then spiked directly to the ties and the tracks surfaced up and supported on double track. This is claimed to be the most expensive street railway track that has ever been built for electric service in this country on so large a mileage."

The officials of the Cincinnati Street Railway Company were recently asked as to how the construction was standing up after nearly five years of service, and stated that it had been reasonably satisfactory. It has been found necessary, however, to shim up the joints two or three times, but as a general thing the foundations are still intact, except in some cases where the soil was porous. In these cases the concrete foundation has gone down, carrying track and all, so that for such conditions broken stone foundations are considered preferable. It should have been noted that the joints were united by means of heavy

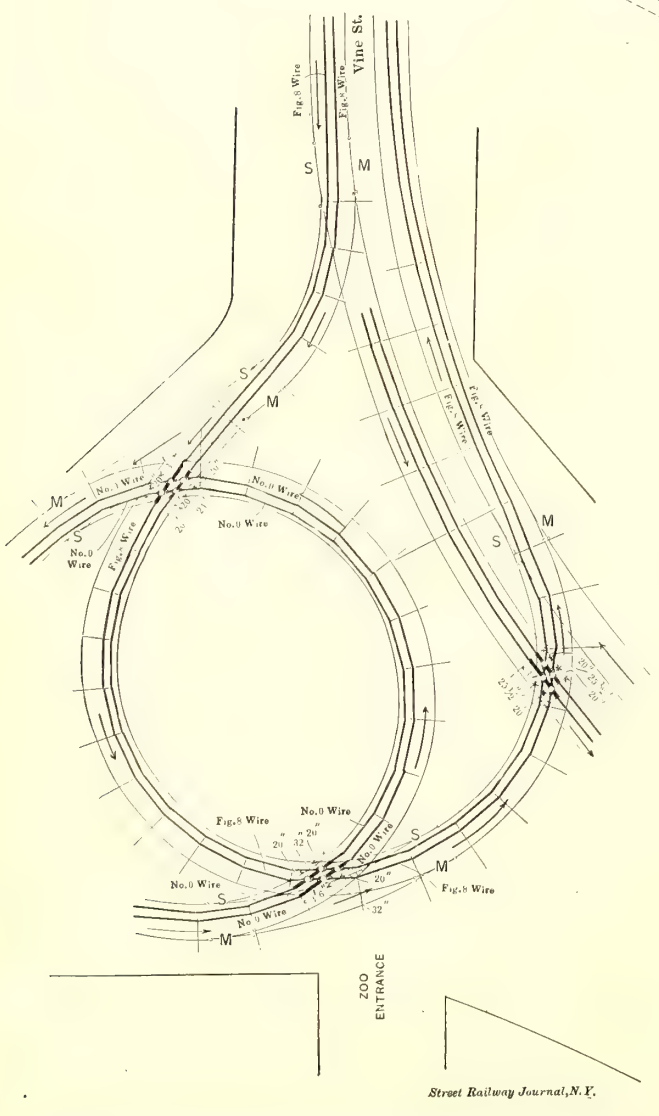
TRACK AND OVERHEAD LINE CONSTRUCTION—FOUNTAIN SQUARE, CINCINNATI

wooden blocks. A foundation of concrete 6 ins. in depth is then placed under the ties and the space between the ties is filled with concrete and tamped. Where asphalt or brick is employed the concrete is placed above the ties, so that they are entirely inclosed in a pocket of concrete. With granite the concrete is brought to a level with the ties, above which are 2 ins. of sand to receive the blocks. On all paved streets a full grooved girder rail weighing 95 lbs. per yard is employed, and which, with granite paving, is required to be 8 ins. in depth. With asphalt and brick paving the same pattern of rail is employed, but the depth is only 6 ins. and the weight 86 lbs. per yard.



"The cost of the new track construction, including the repaving and renewing of the blocks that are worn out, is about $38,000 per mile, single track, or $76,000 for twelve-bolt fishplates, and that the base of the 8-in. rail was 5½ ins. wide, while that of the 6-in. rail was 6 ins.

The company's engineers estimate that it requires considerably more power to operate cars on the grooved rail, which is in general use in the city, than on a side bearing rail. As proof of this it was noted that after the Vine Street cable line was reconstructed with a grooved rail about 30 per cent. more coal was burned in the station to operate the lines than before the grooved rail was substituted. This line has since been changed to electric.



The one remaining cable line is that on Sycamore Street. This was formerly known as the Mt. Auburn Cable Railway, and will be transformed to an electric line in the near future. This change would probably have been made this season had it not been for the excessive rise in the price

of steel rails. This cable line operates over steep grades, one of which is 13 per cent, and contains a compound curve. In case the change is made to electric traction this grade will be cut down, or will be avoided by making a turn into an adjoining street.

In the operation of the system it is found necessary to clean the groove of the rails every day to prevent the wheels from riding upon the flanges. This is accomplished by means of a peculiarly formed hoe or scraper, which is attached to a long flexible handle, and which is manipulated from the rear platform of a car as it passes on its regular route. The attendant fastens a strap to the side and end of the platform and connects the other end of the strap to the hoe handle on a line with the floor of the car. He then stands on the platform and holds to the end of the handle, which comes above the dash and rests against it. By this means the hoe is pressed into the groove with sufficient force to rake out the accumulated sand and dirt as the car passes, and is also in position to be readily lifted at the crossings and switches.

OVERHEAD WIRING ON PRICE HILL INCLINE

OVERHEAD WIRING WITH FIG. 8 WIRE AT ZOO LOOP

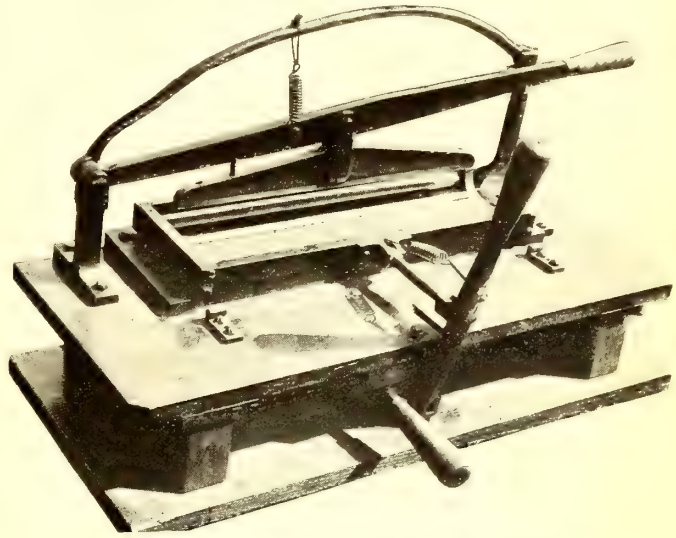
Quite contrary to general expectation, a section of track extending for three or four squares that was laid with the duplex type of construction has stood up all the years as well, or better, than any other section of track. It will be remembered that this type of construction consists of a split rail, laid with broken joints, and supported on cast iron chairs, which, in turn, have broad bases and are supported on concrete pedestals.

The cast weld joints that have been employed are standing up well, except in some sections in which a light 6-in. rail was employed.

In connection with the track construction it should be noted that loops are provided at each of the terminals, so that the cars run the same end forward continuously. The loop at the entrance of the Zoological Garden is interesting in that two lines from intersecting streets have interlocking loops, that is, both lines circle around the same center, but not on the same track, as shown by the accompanying illustration. There is another interesting feature in the track construction on what is known as the Price Hill incline, where a section of track was built upon a long and steep ascent, on which the grades are about 11 per cent. The tracks make a loop in ascending this grade, but the up and down tracks are crossed at the loop, as shown in the accompanying diagram. The ascending cars use the outside tracks both before and after the turn, and the descending cars the inside tracks. This arrangement was adopted as a matter of safety, as it is thought that should a car become derailed on a down grade it would not be so likely to topple over the bank. The accompanying illustrations show the overhead wiring and switches for the

double trolley at this loop, as well as the track arrangement.

Nearly all the cars of the system and those of the Covington & Newport (Ky.) system which enter the city, circle around or pass on one side of Fountain Square, which is in the business center of the city, and in busy hours a large number of cars may be found rounding the various corners. The illustrations on page 431 show the arrangement of overhead wires and switches at Fountain Square. In some cases there are four wires on the streets approaching the curve, so that a trolley may be shifted from one set of wires to another, thus avoiding difficult overhead switch construction. In arranging these switches there are certain dead sections over which the cars pass by momentum, the current being carried past these dead points by insulated cables above the switches. It is interesting to note that the double trolley has held its own in this city since electricity was adopted as a motive power on the principal systems, and that it is in favor with the management. It is claimed that it avoids the danger of electrolysis in the gas and water pipes. The system has recently been inspected by a number of foreign engineers, who have recommended the double trolley for use on some of the new lines in England and on the Continent, and the electrician of the company is frequently in receipt of letters from foreign engineers and municipalities asking as to the working of the double trolley. When people become accustomed to it, the double trolley is not thought to be much more unsightly than the single wire, with its supports.



Notes on the Cincinnati, Newport & Covington Railway Company

An additional unit is being installed in the power station of the Cincinnati, Newport & Covington Railway Company, consisting of a cross compound condensing engine of the Corliss type, manufactured by the C. & G. Cooper Company. The engine is rated at 1200 h.p., and will be direct coupled to a 800-kw. Westinghouse generator, which will give the station a total capacity of 4000 h.p. The original capacity of this station consisted of four 500-h.p. vertical compound condensing marine engines, each of which drives by means of belting a generator of the M. P. type, rated at 500 h.p.

Since the former description of this power station in these pages in the issue of June, 1894, an additional unit of power has been installed, consisting of a Westinghouse vertical compound engine direct coupled to a Westinghouse generator of 375-kw. capacity.

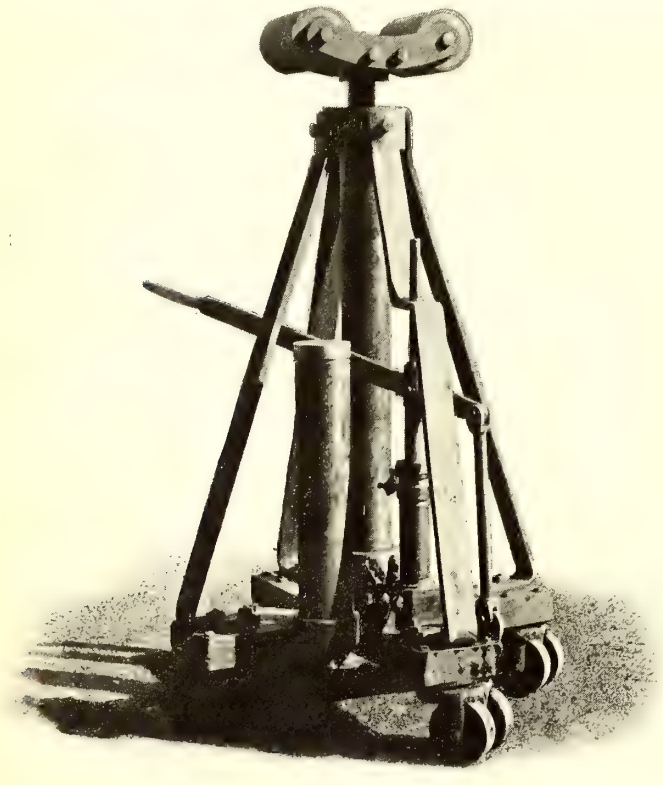
The original boiler equipment consisted of six Stirling boilers and four of the B. & W. type, with a total normal capacity of 4250 h.p. Since the former description of this station the old type of stokers has been removed and those of the American type have been substituted. There has also been installed a mechanical draft appliance with economizers, which were provided by Westinghouse, Church, Kerr & Co. It is estimated that since the installation of the economizers and forced draft a saving of at least 10 per cent has been effected in the cost of coal. The steam pipes leading to the engines have also been changed, by which it is estimated a saving of 5 lbs. in steam pressure of the engines has been effected over that of the old method of piping. The boiler room is provided with cold storage bins and an automatic coal-handling apparatus. There has also been an important change made in the method of providing feed and condensing water. Formerly pumps were installed on a movable platform, which was supported by inclined tracks which led down the bank of the river, a distance of 800 ft. from the power station. The pumps were operated by steam taken from the boiler plant. In place of this a well, known as the intake well, has been sunk 20 ft. deep beside the river. On the bank not far from the power station a second well 50 ft. in depth has been dug. This well is about 20 ft. in diameter, with a brick and cement wall, and is provided with three duplex pumps of the Stilwell & Bierce type, having a capacity of one and three-fourths millions gallons each per day. The pumps are located on a level with the surface and housed in. This well is connected with the intake well, and by the new arrangements it is expected that a saving of $3,000 a year will be made in providing water, as in connection with the above described wells there are two settling basins, which have a capacity of 250,000 gals. This will provide feed water, as well as condensing water. Formerly the feed water was obtained from the city mains. With the various economical features installed in the station the daily coal consumption has been reduced from 44 tons to 25 tons.

What is now known as Soup Creek coal is employed for fuel, and is delivered by cars from C. & O. R. R. The entire power for operating the system is now derived from this station. The second, or auxilliary station, or what

ARMATURE COIL FORMING MACHINE

was the first electric station established by the company, has been abandoned. The old station was located at Second Street, near the end of the Suspension Bridge, and had a mixed equipment of engines of the Armington & Sims type and McIntosh & Seymour make, a 400-h.p. Corliss engine of the Lane & Bodley type, and a 500-h.p. vertical marine engine like those described in connection with the main power station.

CAR HOUSE AND REPAIR SHOP



The company is building a new car house and repair shop, to be located near the main power station, which is at Newport, on the Licking River, near Eleventh Street. The car house has a ground dimension of 90 ft. x 375 ft., with a basement under the rear end for storage and possibly for light repairs. The front part of the building is two stories in height, and the second floor will be occupied by offices, drafting room and reading room for the employees. The repair shops consist of a machine shop, blacksmith shop, storeroom and office under one roof, 60 ft. x 180 ft., and a double building, to be occupied as a paint shop and woodworking shop. The ground dimension of each of the latter is 50 ft. x 110 ft. When finished the plant will be equipped with a full line of wood and metal-working tools, and with all the latest labor-saving devices that can be found, including dismantling pits, improved punches and

shears, cranes, hand lifts and pulleys, as many as may be required.

CARS

The standard closed car of the company is of the accelerator type, and those that were put in service on the lines in February, 1894, are still standing up and giving excellent satisfaction. The Peckham truck has been substituted on most of the cars for different types of trucks formerly employed. This is the extra strong No. 7 B, with a 7-ft. wheel base. The open cars with reversible and folding seats are also still the standard with the company. The duplicate brake equipment that was designed to operate the brakes on the inside of the wheels, and which was employed some years since, has been abandoned, as it was found that, used as an emergency brake, it was not necessary.

As the cars cross a number of bridges, the open cars are provided with a wire screen on each side, which is attached to the outside post, and which extends the full length of the car, so that the passengers enter and leave at the rear platform, as in closed cars. This is rendered necessary for

HYDRAULIC ARMATURE LIFT

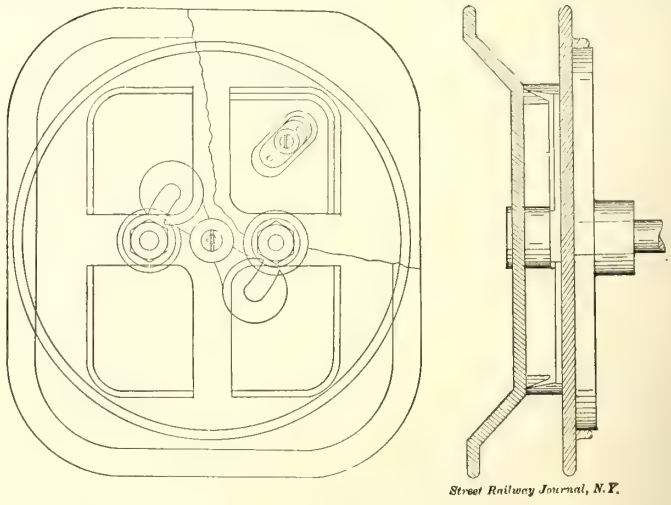
the reason that a number of bridges are crossed and in a number of places there is a clearance of only 6 ins. between the cars and the bridge trusses.

MOTOR REPAIRS

For conveniently removing and handling armatures a 1000-lb. home-made hydraulic jack is provided, the pump of which has a stroke of $2\frac{1}{2}$ ins. The cylinder and plunger are supported by means of four flat bars, which rest on a square base, and which is provided with caster rollers, on which it is readily shifted about. The upper end of the plunger is provided with a pair of rollers in a curved base, which serve to receive and hold the armature. No track is provided in the pit for shifting this device, as the casters serve for this purpose. With this device the workmen are able to remove and replace the No. 3 Westinghouse armatures in twenty-five minutes. In connection with the repair department, an armature coil-forming machine is provided, which is illustrated on the preceding page. The application of this machine is apparent in its design, and does not require further description. The motor equipment of the system includes 107 of the Westinghouse No. 3 equipments and ten equipments of No. 49, with type K controllers.

WHEELS AND AXLES

The standard axle now employed by the company is $3\frac{5}{8}$ ins. in diameter, with a $3\frac{1}{2}$-in. journal, while the boxes are so designed that a 4-in. axle can be used if necessary.



In fitting wheels, the practice is to turn the wheel to fit the axle with very little taken from the surface of the axle. In some cases the gears are pressed on the axles without keys. The gears are cast with large hubs and provided with large bolts and bored 1-3000 in. smaller than the axle. The wheels are put on axles under a pressure of 37 tons.

The personnel of the operating staff of the road has recently changed: J. C. Ernst is president; J. R. Ledyard, general manager, in place of Thos. M. Jenkins, who has recently resigned to accept a position as general manager with the St. Louis & Suburban Railway Company, St. Louis, Mo., and A. C. Harrington, as superintendent of motive power and electrical engineer.

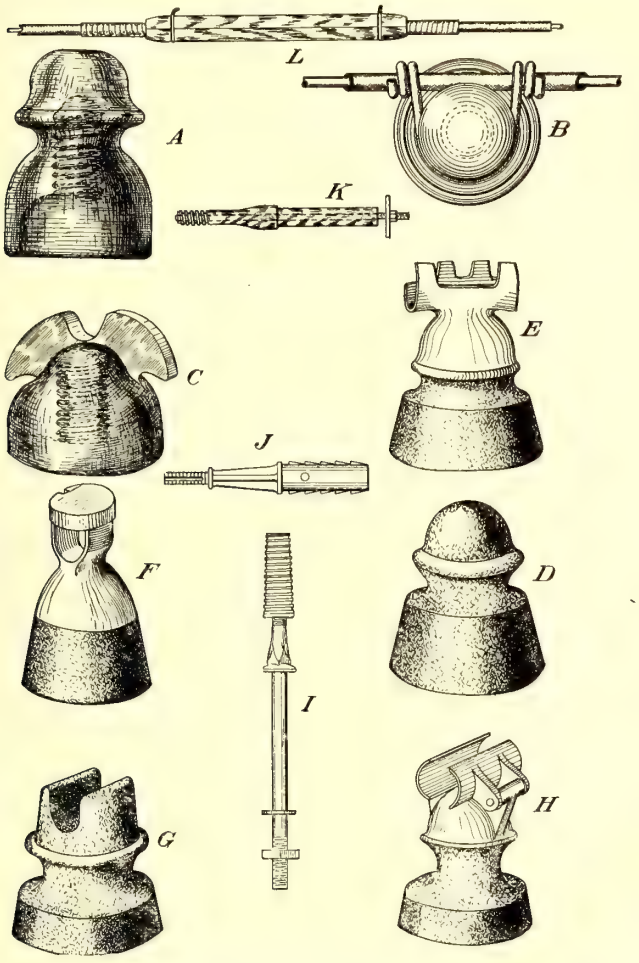
Convenient Coil Form

Several types of field coil forms have been illustrated in the Street Railway Journal, but all have been quite different from the one shown herewith. It is employed in the Kensington repair shops of the Union Traction Company of Philadelphia, and has been found so convenient that it is employed for all the motor field winding on that large system.

The form is of iron, as that has been found to keep its shape better than wood, and is made in two parts as illustrated. The two plates composing the form are held together by means of two studs. The studs are screwed firmly in the inner plate. The outer plate has two holes large enough to allow the heads of the studs to slip through. At the end of each of these holes is a short slot cut on the

FORM FOR WINDING MOTOR FIELDS

arc of a circle. To attach the outside plate to the inner the studs are first slipped through the holes in the outer plate and then given a short turn.



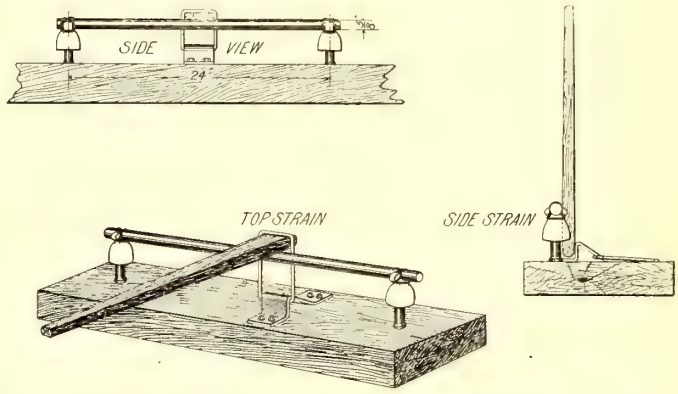
All that remains to be done now is to give the studs one or two turns, which will bring them down firmly on the outer plate. After the coil is wound it is another simple matter to loosen the studs, when the studs are slipped through the large holes, releasing the outer plate. This requires a few seconds only, and it is this ability to take the form apart quickly which makes it so convenient.

Overhead Line Construction II.

BY ALBERT B. HERRICK

THE INSULATION OF THE FEEDER

In addition to the insulation covering on the feeder wire, a second insulation should be introduced between the feed wire and its mechanical supports. The materials generally used for this purpose are porcelain, glass and compounds



FORMS OF FEEDER INSULATORS

of mica and shellac, rubber and asbestos. The mechanical properties of this insulation should be such that it will stand strains without fracture, and that the surface will not absorb moisture. Glass or porcelain is generally used for No. 000 feeders or smaller, but for larger feeders with long spans, exceedingly strong insulators should be selected, especially where it is also necessary to use an iron pin. Porcelain has been greatly improved in strength during recent years, and the present method of firing it in the kiln has thoroughly vitrified the body of the insulator, still leaving it tough. The method of testing a porcelain insulator, to determine whether vitrification has taken place, is to break it and apply analine ink to the fractured surface of the broken portions of the body. If, after washing, a general discoloration of the porcelain is found, it has not been properly fired.

In the saddle form of insulator, shown at C, with butterfly wings, the portion of the insulator where the wire rests should be provided with rounded edges so as not to abrade the wire, if there is any movement of the feeder due to temperature changes. The flarings of the petticoat should not be too wide to allow water to spatter under them from the cross arm, or too narrow, as this condition invites insects to make cocoons and nests in them. Where a flaring petticoat is used, the top of the cross arm may be rounded and the edge of the insulators made helmet-shaped, so that the drip shall fall outside the cross arm, but these considerations are more pertinent in high tension transmission work.

The strength of insulators can be tested as follows: Place two of the regular pins 24 ins. apart in a wooden beam, 4 ins. x 6 ins., and tie down into the top of the side groove of the insulator a ⅝-in. rod of iron 28 ins. long. A strain by a lever that will give a permanent set to this rod should not fracture the insulator. A test should be given for both top and side strains. The method of making this relative strain test is shown herewith. No copper line can withstand such strains to an insulator as these tests impose. The strain of the copper conductor is a limiting mechanical factor beyond which it is not profitable to increase the strength of the pole line.

The composite insulator, which is formed of a metallic saddle for the feeder and a metallic bushing for the pin, is a form of insulator largely used. These two metallic parts are held together and insulated from each other by insulating material which is generally molded into place under heat and great pressure. The desirable qualities in the composition used are that it have sufficient mechanical strength and that the strength be maintained when the temperature of the insulator has been raised to 150 degs. F. The worst fault of these composite insulators is that they become plastic in warm weather and yield to conductor strains. This composite insulating material should not be affected by rain so as to dissolve any of the substances in

DEVICE FOR TESTING STRENGTH OF FEEDER INSULATORS

the composition, as a roughened surface will hold dirt and produce a leaky surface.

Where the line passes through trees it must be protected from contact with the latter, as the movement of the branches by the wind abrades the insulation of the wire.

For cases of this kind the split wooden sheath, shown in "L" on this page, is often used. This should be held firmly in position so as to not slip along the wire, but the really best protection, where it is possible, is to pull the feeder away by guying it to another limb. If a split porcelain insulator is used to enclose the feeder and the guy twisted around the porcelain insulator and some tension put on it to an adjacent limb, the tree and the wire are both free to move without any considerable strain.

THE MOST ECONOMICAL ARRANGEMENT OF FEEDERS

The next matter to be decided in line construction is the proper amount of copper to use and its most economical disposition. We will first view this question from commercial considerations; but returns in the way of investment in copper may be from several sources. The first and direct loss caused by a deficiency of the copper in a feeder system is in the loss of energy; second, in the increased depreciation of the equipment due to the higher temperatures

attained by motors operated by low voltages; third, in the added expense of operating more equipments where a given headway between them is maintained, due to the lower maximum speeds and slower acceleration under low voltages.

In connection with the energy it can be seen that the smaller we make the feeder for a given load, the greater the loss and the less will be the fixed capital charges against this feeder per annum. On the other hand, the cross section may be increased until the interest charges are largely in excess of the energy saved. Thomson determined that the most economical sized feeder to use was the one in which the annual interest charges were equal to the annual cost of the energy lost, and this is accepted as a general rule for the determination of the proper capital investment in the feeder. To the cost of feeder should be added the cost of its insulation and pole line or of conduit, and the interest charge can be fixed by local conditions.

The price per unit of energy generated in the station should be based on that charge on which a power station could sell all its output without loss, and the items which enter this charge should be coal, water, labor and all the supplies necessary to create this power; this cost should also include the interest charges for the power station upon its investment, taxes and insurance. The power station should also bear its proportion of general expenses, in the ratio which the capital invested in the power station bears to the total capitalization. In other words, the cost should be that at which this power could be sold without a profit or without a loss.

Calling this the prime cost the cost for the losses on the line will be some value less than this cost, per unit lost, depending upon cost of this additional production of energy, and the cost varies on each plant for this loss, but the cost of increasing a load 10 per cent on a station will make little difference in its consumption of coal, oil and water, except where an extra unit has to be operated to maintain the usual 25 per cent overload, allowed in operating capacity, and under these conditions the losses in this added unit are chargeable to the line losses. Strictly speaking, the fixed charges belong to that portion of the energy of the station which produces a revenue, and again the increased loading of a unit brings up its efficiency, and this line loss is reflected in decreased cost of the total output.

If these costs and current deliveries are determined for any road, it is very easy to construct a table in which the cost of the energy lost is compared with the capital charges, and this determines which size of wire can be most economically used. The next and most difficult question is the fixing of the current required to propel the car or cars which are fed by the copper to be supplied.

Assume the energy consumption as 1.2 kw. per car mile for level track, 28-ft. car body weighing 18,000 lbs., single truck, two G. E. 800 motors with K2 controller, and speed 10 miles per hour. This, with 500 volts, gives the average of 24 amps. per car for current delivery. On the first step the car would require 60 amps. at 500 volts; but, with this flow of current, a drop will occur over the copper conductors. Say the voltage fell to 450 volts with the controller on the first notch, then the current will be 54 amps. The second notch of the controller cuts out $4\frac{1}{2}$ ohms., and this should largely be taken up by the counter e.m.f. of the motors, which have started and commenced accelerating.

The speed gained on the first notch reduces the current obtained when the second notch is reached, and the greater the feeder drop the slower the acceleration. The greater the amount of energy required to bring the equipment to speed, the higher will be the temperature attained by the motors, and the greater the rate of equipment depreciation and the maximum demand on the power station. These losses and station investment can be reduced by greater line copper investment.

In this consideration, both the copper and ground return system have to be considered. Allowing 20 per cent drop, which means an effective voltage delivery of 400 volts to the equipment, the maximum current at starting, which will be on the second notch, can be assumed as about 90 amps. Say that 8 per cent drop is allowed for the ground returns, and 12 per cent for overhead copper; this gives a maximum feeding resistance of two-thirds of 1 ohm per equipment. The average demand then is 24 amps. per car, and the maximum demand 90 amps., for the case under discussion.

The effect of grades is to both increase the starting current and also the running current value. The chart here-

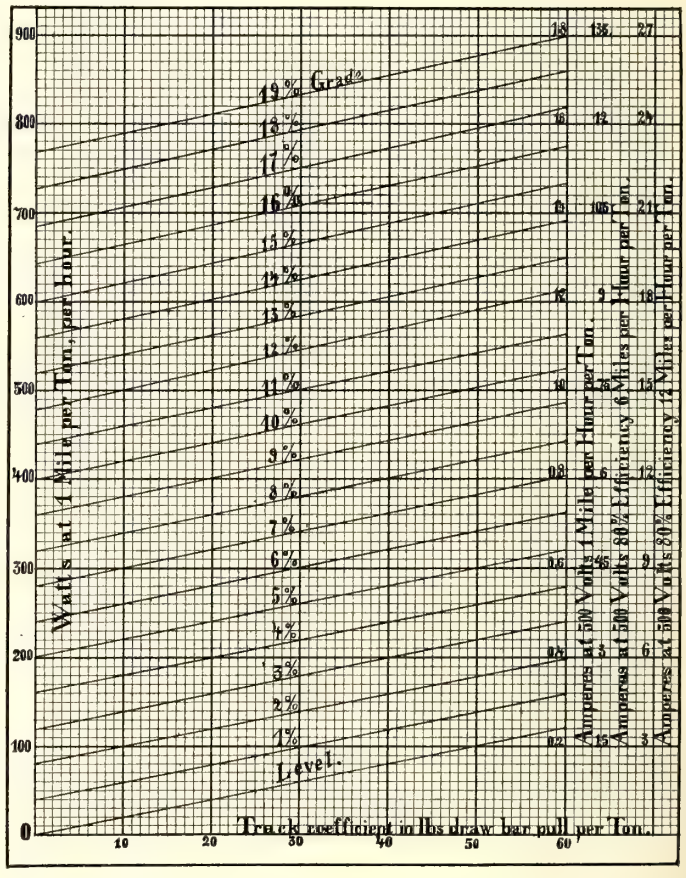


DIAGRAM SHOWING AMPERES REQUIRED PER TON WITH DIFFERENT SPEEDS, GRADES AND TRACTION COEFFICIENTS

with shows the relation which exists between the traction coefficient, which is plotted as ordinates on the chart, and the watts at 1 mile per ton per hour, which are plotted as abscissæ on the chart. Diagonal lines are drawn across the chart corresponding with grades from level up to 19 per cent, to assist in giving what is really required, i. e., the amperes flowing for different speeds and grades. On the right hand of the chart is given a scale in amperes, assuming the current delivery to the equipment is at 500 volts, for speed of one mile per hour. While the current delivery is not a rectlinear function of grade and speed, approximately proportional results can be obtained by multiplying the speed on grades by the weight of the car by the current given in this chart at the required grade, will give the total amperes required.

As an example, suppose we have a car weighing 18,000 lbs. climbing a 4 per cent grade at 10 miles per hour, with

a track coefficient of 25 lbs. Pass up the vertical line 25 until the diagonal line indicating 4 per cent is reached, then pass horizontally until the 1 mile per hour scale of amperes is reached; this gives 0.42 amps. per ton. For 9 tons this would be 0.42 (amps.) x 9 (tons) x 10 (miles) = 37.8 amps. The two other vertical columns at the extreme right of the chart, one 6-mile speed and the other 12-mile speed, give the current required, including 20 per cent loss on the line. For example, suppose an 8 per cent grade, 30 track coefficient, car weighing 20,000 lbs., running at 8 miles per hour, at 20 per cent transmission loss. This will give 5.7 amps. per ton, adding 1/3 more for increased speed and multiplying by 10 for weight in tons would give 5.7 x 4/3 x 10 = 76 amps. This, of course, is without any rheostat in circuit with the motors. The same problem can be worked out by the table given below.

It is extremely difficult to give the exact speed at which a car will ascend a given grade, for each equipment will fall in speed in mounting a grade until the counter e.m.f. of the motors has been reduced to such a point that the current is sufficient to propel the car up the grade. This point is variable, depending upon the equipment.

In considering the copper service on grades, the cars coming down grade require less current than those ascending, and generally above a 3 per cent grade a car will float with open controller after being started up to speed. It is very important to maintain potential at grades in order that the car can climb the grade at good speed, and to reduce the heating of the motors; and if the schedule can be maintained up grades the motorman will not be called on to make up time by coasting too fast down grade.

The usual practice of feeder taps from trolley to feeder every ten and eight poles on levels should, on grades, be reduced to six and four poles between each tap, in order to maintain the feeder pressure at trolley wire.

The headway of the cars will have to be known in order to get the average current demand, but the average demand is taken care of when provision is made for the maximum demand.

In the operation of a railway it is necessary at times to operate more cars over a section of track than are required by schedule, and fixing the maximum current demand is purely a local problem. The maximum demand is usually figured for a total drop of 140 volts where 500 volts are used at the station, and 150 volts with a 550 station voltage.

There are a number of ways in which copper investment can be reduced to handle this maximum load; one is to have a two-potential railway board, use a separate generator whose voltage can be raised to compensate for the unusual feeder losses and throw these feeders on to this higher potential bus, or a generator can be thrown in series with these feeders, and used to add voltage to that already supplied to the bus. In such a case this current would pass to the loaded feeders through the series field and the armature, when the dynamo becomes automatic in its action and boosts the current. By estimating the possible number of cars that could be massed together and using the constant given for each individual car, the maximum demand can be determined. On level roads the main ampere meter readings average 65 per cent of what would be acquired by assuming all cars operating at once. Where traffic is dense, and stops many, this is increased to approximately 70 per cent of figured maximum average demand.

EXAMPLE.—Given a car weighing 12,000 lbs. loaded; the grade at the point where we wish to know the current is 4 per cent.; speed required is 7 miles per hour; traction coefficient on this track is, say, 20 lbs.; motor efficiency is 80 per cent; current delivered at 500 volts. The current taken at this point will be equal to watts in table, shown at intersection of 4 per cent grade and 20 coefficient, multiplied as follows:

$$\frac{198.9 \times 7 \text{ (miles per hour)} \times 6 \text{ (tons weight)}.}{.80 \text{ (efficiency)} \times 500 \text{ volts (pressure)}} = 20.88 \text{ amps.}$$

mand, but types of equipments, trucks and weight of car, and motorman, are all variables entering into this problem, and they require careful consideration on new roads; but on old roads, where the copper has to be reinforced, these variables can very readily be given fixed values, and the profit or loss for additional copper can be easily figured.

There are a number of methods by which current is supplied at a given potential along a trolley wire. In some the trolley wire is divided up for safety, a method which largely increases the copper cost of delivering current at a given potential. The simplest system consists of a single trolley, fed at one end; in this the car gradually loses potential as it passes away from the station. With a 12 per cent drop, the distance in feet which the car can go and not exceed the fixed drop is the product of resistance per foot of trolley multiplied by the current demand, divided into the drop in volts allowed on the trolley. A double trolley will give twice this distance, if the current demand remains the same. Fig. 1 shows the drop in volts at each point on the trolley.

After this distance has been reached the trolley has to be reinforced by a feeder leading from the station. Fig. 2 shows the redistribution of potential due to such connection. A car located between the station and trolley tap will now be fed two ways; one through the trolley direct, and the other through the feeder. The drop will now be due to two conductors in multiple, which will be the product of the resistance of the trolley wire from the station to the trolley wheel multiplied by the sum of the feeder resistance, plus the trolley wire resistance from the wheel to feeder connection. If this product is divided by the sum of these resistances, it will give the resistance of these conductors feeding in multiple, which multiplied by the current required by the car will give volts drop, which is the quantity sought. It will be noticed in this consideration of feeders that the farther from the station the current has to traverse the trolley in order to reach the feeding point, the less effect the feeder has on the potential delivery to the car. Fig. 3 shows taps at frequent intervals between the feeders and the trolley, gaining the maximum usefulness out of the feeder.

It has been the practice to isolate feeding sections by placing line circuit breakers in the trolley wire and providing independent feeders, so that if the trolley falls or a feeder becomes grounded it will not shut down the whole system. Other simple means can be used for the same effect and yet obtain the multiple feeding effect of all feeders, as by introducing between the terminal of one feeder and the feeder connecting an adjacent section, a safety catch or automatic circuit breaker, mounted in a box located on a pole. In Fig. 4 the car with open independent feeding sections will have a drop of 150 volts with a 300 amp. maximum, and connecting feeders, together with automatic devices as shown, will reduce the drop to 30 volts with the same load, or one-fifth the single feeder drop.

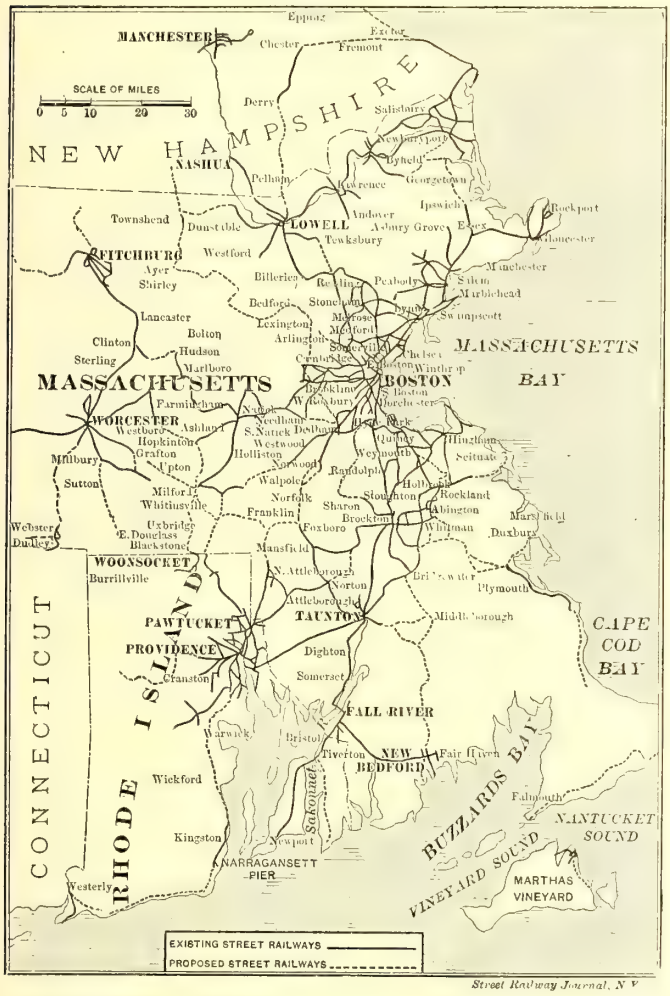
Judge Miller has handed down an important decision in one of the tax cases of the city of Louisville against the Louisville Railway Company. The amount involved is $151,824, this sum being claimed by the city as unpaid franchise and personal taxes due from the street railway company for the years 1894, 1895 and 1896. The company claims these taxes were uncollectable, owing to new ordinances passed by the City Council, and also that the taxes are excessive. The court holds that under the present laws of the State no corporation can acquire, by contract or otherwise, an exemption from the burdens of taxation, and that the payment of a license tax cannot be pleaded in bar of an ad valorem tax.

The Possibilities of the Trolley Excursion Business in Eastern Massachusetts

BY ROBERT H. DERRAH

It is surprising that until the last two years comparatively nothing had been done in Boston in the way of conducting excursions on the electric cars of the city and the neighboring country. Probably in no portion of our country can be found a greater variety of scenery and places of historical associations than in Eastern Massachusetts, and the whole district has been covered with electric railways. But, apart from running out a special car whenever it was ordered, and purchasing a couple of parlor cars, which have been in more or less demand for theater parties or on the occasion of the annual football games, practically nothing had been done by the companies which were to secure the greatest returns. When, in 1896, I began the publication of the "Street Railway Guide," telling people how to reach the points of interest on the electric lines of Eastern Massachusetts, I became firmly convinced that there was a vast amount of "pleasure travel" on the railroads which brought in a tremendous amount of business to the companies. Since then I have seen plenty of evidences that such was the case, for the circulation of the "Guide," which was designed to be primarily of benefit to people who wish to travel on the electric cars for pleasure, has increased so much that it is evident that the travel of this kind has increased enormously within the last two or three years. Recent developments have made it possible to make the trolley excursion traffic an important factor in the street railway business of Eastern Massachusetts.

In the first place, attention is called to the facilities for special excursions on the street railways in this part of the country. These form the largest connected system of street railways in the world, running from Nashua, N. H., on the north, through Boston to Newport and Providence, R. I., on the south, a distance of 130 miles. Eastward they extend to the tip end of Cape Ann, some 45 miles, and westward to West Warren, Mass., some 80 miles. All this district is covered with a network of electric lines.



Heretofore one of the great difficulties of conducting trolley excursions, except of limited extent, has been the fact that special cars of one company were not allowed to run over the lines of another. Even in cases where this prohibition did not exist, tracks of different companies were not actually connected, so that a change of cars was compulsory. For this reason each company was obliged to run its own special cars to provide for any long trolley trip that might be planned. For the past three years these suburban roads have had, and are having, these missing links connected up. At the present time, it is unreasonable to expect a large corporation like the Boston Elevated Railway, operating some 1200 cars in a congested city like Boston, to assume the responsibility of allowing the cars of ten suburban street railways which connect at its various termini to run over its tracks, but I feel certain that within the near future all the street railway lines within a radius of at least 50 miles of Boston will be virtually under one management, and when it has reached that point some satisfactory arrangement can doubtless be made whereby special cars can be run over each other's tracks to the advantage of both companies.

A gentleman representing some 250 Sunday-school children called in reference to their annual picnic. I handed him a list of the several picnic grounds within easy reach of Boston especially adapted for that purpose. He selected one, and after visiting the place, stated that although

he had lived in Boston nearly all his life he had not believed there were such beautiful scenery and trolley rides in New England. This is an example of how little the people know of the beauty of the country that surrounds them.

The trolley excursion business in this section of the country has a much broader field than in other parts where it is operated on a very large scale, such as Brooklyn, for example, they have Coney Island, Bergen Beach, North Beach, Jamaica, Flushing, etc., while we have numerous beaches, the finest in the country, where a great many wish to go; on the other hand, we also have inland parks and country for those who wish to spend a quiet outing.

There are many disadvantages at the present time, resulting from the fact that the roads are run independently;

MAP SHOWING ELECTRIC RAILWAYS IN EASTERN MASSACHUSETTS, RHODE ISLAND AND NEW HAMPSHIRE

for instance, cars frequently do not make good connections, and if a special car followed a regular car on a single track, and the regular car is behind time, a half-hour wait is often necessary at the terminus, as the country lines frequently run on a half-hour schedule. The consolidation of the various lines will obviate this difficulty.

Another factor which has prevented the development of the trolley excursion business in this part of the country has been the lack of suitable cars. Except for the two parlor cars owned by the Boston Elevated Railway, there have been no cars which were especially adapted to excursion business. Regular open or closed cars were run out as might be needed, but these are not well adapted to the use of trolley parties. I think the time is not far distant when Boston will be the foremost in the trolley excursion business, under the management of a separate company, with cars especially equipped for this class of traffic, built on a plan to combine buffet and parlor car, fitted with all conveniences. Each car would have its own motorman and conductor, with an experienced man serving as a guide, if desired. With these cars a party could go over the different railway lines, visiting points of interest and stopping wherever desired, traveling for a week or more without going over the same country twice, as the lines connected make up a system of more than 1200 miles.

It would seem that the possibilities of such a business are practically unlimited. It only remains to secure the cars and acquaint the 2,000,000 people with the advantages of this form of excursion. Compared with railway excursions they might be made cheap, and the passengers would have the advantage of seeing the best, rather than the most uninviting, of the country traversed. Taking their own time, stopping when and where they pleased, the trolley excursionists making up a party have at their disposal the resources of all the electric companies for only an extra fare on each line, or even less. Short-distance excursions have been for years popular in London and the large cities of England, and in a country where there is so much to be seen, and an endless diversity, the prospect for this class of business is an attractive one. Special knowledge of street railroading is, of course, necessary to successful management, but the passenger has no need to know anything more than where he wishes to go. A series of trips can be arranged covering a diversity of points of interest, for a half-dollar or a dollar, providing a whole day's outing, and giving the passenger an intimate knowledge of the country about him. Within a short time this business is likely to develop into an important one, and nowhere is there a better field for its operations.

Shop Wrinkles

BY J. F. HOBART

Repair shops now frequently get into the habit of using the slowest possible speeds on any machine. A lathe is often back-geared when not necessary, and when a faster speed would not only do more work for the owners, but would actually make the work easier for the operator!

A case of this kind comes to my mind, of a shop where about eighty men were employed in all branches of car work. The shop had been for a long time under the control of an easy-going mechanic of the old school. When a new management took hold of the road a young mechanic, with more modern ideas, was put in charge of the shops. He made the attempt to have faster speeds used on all the machines in the shop, but had very poor success in so doing. As long as he was present the faster speeds would be used, but tools would break or get dull quickly, and some excuse was surely found for putting the work back on the old speed again.

One Sabbath day the foreman of the shop went quietly to work and speeded up the line shaft, so that all the machines were brought up to about the required speed. This act caused a vast howl of indignation, and sixteen men threw up their jobs and left. But the high-speed line shaft stayed, the high-speed machines did likewise, and the tools stopped getting dull or breaking, proving that the slow speed of the men, not the high speed of the machines, had been the cause of trouble in that direction.

The scheme is a good one to apply to a large number of existing shops, thereby improving both the quantity and the quality of the work turned out. Aside from speeding up the main line shaft, it is frequently profitable to speed up the steam engine. Then, not only will the speed

be increased, but the power developed by the engine will be increased also.

With small throttling engines there is usually no reason why the speed should not be increased at will, but with Corliss, or other engines with large pulleys, the safety of the wheel at the proposed speed should be passed upon by a competent mechanical engineer before making a change. This precaution is necessary, because many such engines are already running close to the speed limit.

STRAIGHTENING AXLES

A good many slightly bent car axles can be made as good as new (nearly) by judicious straightening. It does not answer well to straighten axles cold. Thus treated the metal seems to have taken a "double set," and will bend much quicker than before either the first or second bend was made. Axles should always be straightened hot. Thereby the strains are removed, or neutralized, and the metal is almost, if not quite, as stiff there as at any other part of the axle.

To properly test the straightness or crookedness of an axle it should be placed between centers. In no other way can an exact test be made, although a close approximation of the center method may be arrived at by placing the axle on friction wheels, said wheels being placed at the extreme ends of the axle. An old lathe bed placed close to the straightening forge is about the best rig for testing axles. A pair of old tailstocks may be rigged on, stout enough to stand a rap from the sledge upon a hot axle when necessary.

MILLING AXLE-BOX HOUSINGS

Jig-work is the passport to economy in street railway machine-shop work. When hundreds of castings are to be milled in two or three places, then drilled and tapped, it does not pay to do the work under an ordinary drill press, using an end-mill for the surface work, and locking up the casting for the drilling and tapping. If only a few dozen castings need drilling the hand method is well enough, and the castings should be laid into a face-plate vice, one at a time, after being milled or planed ready for drilling.

A short iron level should be laid across the milled upper surface of the casting, but if necessary a very short level may be used, placed upon a parallel piece of metal which is long enough to reach across the opening in the casting. Two parallel bearings below the vise will allow the casting to stand upright between the vise jaws. Then the level is applied, the casting adjusted until it is level both ways when the vise is closed, the level being kept in place to reveal any possible movement which might throw the casting out of true.

The drilling may now proceed, the holes having been previously laid out and marked by circle and four center-punch witness marks. After starting the drill it is brought central by the usual method of chipping out one side of the hole with a small three-cornered or half-round chisel, so as to draw the drill over.

All this work and loss of time would be dispensed with if a template had been provided, into which the casting could have been fastened at the beginning by a turn of a lever or screw. Then it could stay there during both the milling and the drilling, thereby causing all finished surfaces and holes to be in line with each other, and requiring no leveling or hole chipping.

IRON AND STEEL CUT TO LENGTHS

Among the unprofitable work often done in car shops, smithies and machine shops is that of cutting up round and flat bar iron into the lengths required. Merchant iron and steel can now be bought in lengths required (cut up at the mill) at a very trifling advance, if any, over the price of regular bar material. When a man and machine are seen day after day working in slow moderation, and with still slower efficiency, to mangle material into short pieces, the contrast becomes too great. The iron cut at the mill is smooth and square, and of exact length—much more than can be said of the haggled-off stuff cut in the average car shop.

This idea may well be carried further than to merchant iron. Many shops keep men and machines running continually on standard bolts. It may be a surprise to some shop managers to learn that manufactured bolts can be bought in quantity at a very slight advance over the price they are now paying for the iron to make bolts of. In a number of shops this has been found to be true, reckoning the iron and bolts pound for pound.

Repair Shop Accounting on a Small Road

The Wilmington City Railway Company, of Wilmington, Del., is employing a convenient and systematic method of keeping repair shop accounts, the invention of Joseph Kuen, master mechanic of the company. While not elaborate, it answers perfectly the needs of the company in determining the life of the apparatus used on the road, and takes but little time to keep up.

The form below is that used in the shop, and gives exactly what apparatus is changed, as the shop foreman checks off on the list any part which has been renewed:

WILMINGTON CITY RAILWAY COMPANY.

This report is sent to the master mechanic, who enters the date and extent of the changes in a truck record book, in which a page is given to each truck. Each truck is given a number, and the pages are numbered in consecutive order, corresponding to the truck number, and the date of removal is given opposite each item.

Truck and Motor Changes.....

The car body repairs are entered in a separate book, which also contains data relating to the equipment of the car body, so that a glance at this book will tell the purchasing agent just what parts and equipment to order for

repairing. These data are grouped under the following headings:

Length over bumpers.	Style of seats.	Heaters.
" " all	Size of side glass.	Controllers.
" " body.	Size of vestibule glass.	Trolley base.
Number of windows.	Register.	Rheostat.
Color panel and coves.	Chandeliers.	

The company also has a third book, called an "Armature Book," which contains a page for each armature. All armatures are numbered, and all repairs on the same armature are entered under the proper serial number. This book is written up from the armature winder's day book.

Mr. Kuen says it is his usual custom to allow the reports to accumulate for some days, and then to enter them into the above books at one time. It requires only about a half an hour for one man to enter in this way the work of one week in the repair shops.

Accident Blanks

The accident blanks given below are those in use on the Brisbane Tramway Company, of Brisbane, Australia, the general manager of which is J. S. Badger, who is well known in America. These present several features which are somewhat novel, and are, at the same time, complete and compact.

Two forms are used. The first is a single sheet, shown in Form 2, and is intended to cover minor accidents. That in Form 1 is more complete, and is intended for reporting more serious accidents. It is filled out by the conductor in ink after he has returned to the car house, and has four pages. The blanks are abbreviated somewhat in the re-

PRIVATE.

Brisbane Tramways Company Limited.

ACCIDENT REPORT—FORM NO. 1.

N.B.—This report is furnished for the information of the Company's solicitors, and must be treated as Strictly Private and Confidential.

INSTRUCTIONS.

Employees must report every accident to any individual or to or in connection with any car or vehicle belonging to the Company or any other company or person, which occurs within 14 paces or steps of the tracks or cars belonging to the Brisbane Tramways Co., *no matter how trivial* it may seem, or even if the person states he has received no injury. You must at once obtain all the facts connected with the accident, the names and addresses of persons who met with the accident, and of all witnesses whether on or off the car. If any policemen should be present be sure and take their addresses and numbers, and in any case it is important to get as many witnesses as possible. All the addresses must be obtained in full, with district, street and name of house, or if it has none, then its vicinity to some cross street, or hotel or other business. The most important duty of employees, in case of accident, is to secure the names and addresses of the largest number and the most intelligent and reliable witnesses. In case of a serious personal accident, when persons who saw the accident will not give their names, some employee of the Company should stay with the witness and follow him until he finds out the accurate name and address.

Employees, after having an accident, resulting in damage to person or property, must report same verbally to the first inspector they meet, and also report the same *at once* by telephone to the head office, during ordinary business hours, or to the Cash Receiver's office at Petrie's Bight when the head office is closed.

Accident reports must be filled out in ink and handed to the Yard Foreman before the conductor and motorman leave after turning in the car.

Employees must not under any circumstances, tell any one who their witnesses are in any case of accident, or make any statement with reference to the accident, except to an official of the Company.

Conductors will fill in the diagram on the fourth page of this blank, showing the exact location of car or cars, vehicle or person connected with the accident, naming streets, and cross streets.

FORM 2, ACCIDENT REPORT

production herewith by the omission of a number of blank lines in the page where a general description of the accident is requested.

An Apparatus for Testing Coal, Fuel Oil and Other Combustibles

An oxygen calorimeter for testing fuel oil, coal and combustibles has been constructed by J. R. Chapman, chief electrician of the North Chicago Street Railroad Company, along lines suggested by articles appearing in certain technical papers a year or two ago. The construction of Mr. Chapman's apparatus will be made clear from the accompanying illustration and the following description. A large vessel, *A*, water sealed at the bottom and connected with a pipe fitted with cocks, *CC*, and a funnel, *F*, by which it may be filled and emptied, is also connected with an open glass tube, *T*, extending vertically from the top some 20 ins. or more, and paralleled by a graduated scale, *S*. Inside the vessel, *A*, is a closed retort, or bomb, *B*, into the bottom of which passes a metal plug, *M*, carrying on its top a little cauldron, or "charcoal pot." The bomb is connected at its base with an inside source of supply, *O*, through which oxygen gas may pass into the bomb, expelling the air before it through tube *S*.

The apparatus works as follows: The plug *M* is removed, and one gramme of fuel oil, coal or other combustible to be tested, is placed in the cauldron, and a platinum wire connected with an outside electric battery is immersed in the combustible. The plug is then screwed into position, the vessel *A* is filled with water to a point such that the water in *T* is approximately at *O*. The water is allowed to assume the temperature of the room as nearly as possible, as determined by a thermometer, oxygen is passed into the bomb until the pressure reaches a predetermined testing point, and when all the temperature conditions are stable and uniform, connection is made between the battery and the platinum fuse, the combustible is ignited, and combustion takes place with great rapidity in the oxygen atmosphere. The air in the bomb becoming heated, the walls of the bomb expand, forcing the liquid in *A* further up into the tube *T*, and the maximum point reached by the water is noted on the scale. The initial point having been previously noted, the differences between these readings are compared with the readings found by the combustion of pure graphite, or charcoal, and the relative efficiencies of different fuels are thereby obtained. The whole apparatus is extremely simple, and

OXYGEN CALORIMETER

should be quite accurate within desired limits, and the apparatus can be made in any street railway machine shop without great difficulty.

Milwaukee Accident Report System

The Milwaukee Electric Railway & Light Company carefully classifies all its accidents, both as to their character and, in the matter of payment, as to the year in which the accidents occurred. The classification is as follows:

Collision with vehicles.
Collision with persons.
Collision with animals.
Collision with bicycles.
Collision with cars.
Cars leaving track.
Employees injured when on duty.
Center pole accidents.
Alighting or boarding moving train.
Alighting or boarding stationary car.
Fell in, on, or off car.
Fell off car on curve.
Trouble on account of fare.
Disturbance on car.
Ejectment from car.
Frightened horses.
Electric shock to horses.
Electric shock to animals.
Damage to company's property.
Unusual occurrences.
Miscellaneous.
Power plant.
Lighting.

In the auditor's accident report blank the accidents for each of these classifications for the month and year to date are reported, and the payments are entered in separate columns for the year in which they occurred, so that the total monthly and yearly payments to date appear in both

classifications. The legal expenses connected with accidents are also presented in a number of subdivisions, classified in the same way as are the payments on claims.

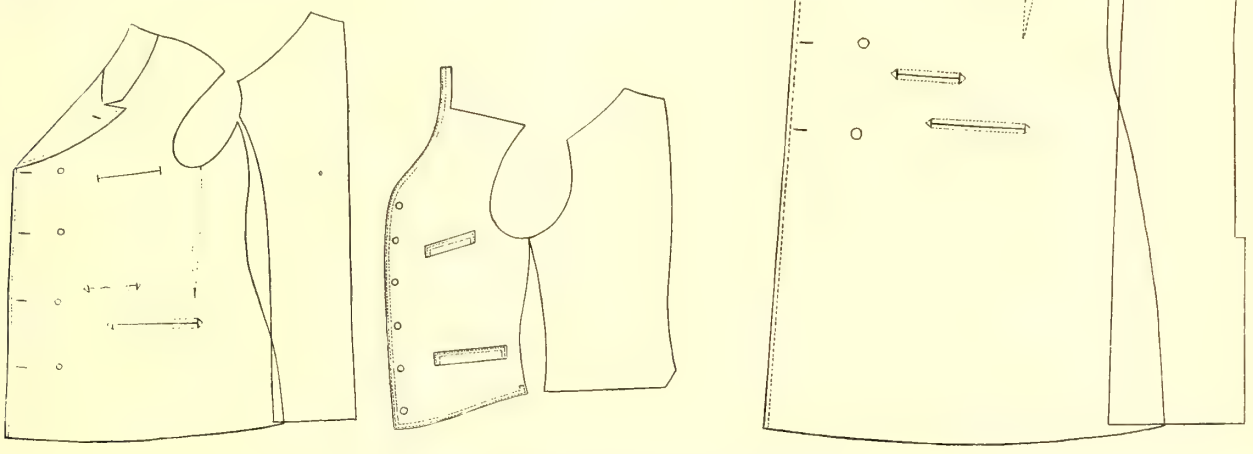
System of Uniforming Men in Milwaukee

The accompanying diagrams and specifications of uniform coats, vests and overcoats for the Milwaukee conductors, motormen, station masters and inspectors will be found worthy of study, as they represent a very careful effort on the part of the management to standardize a system of uniforming their employees in such a way as to make it possible for the latter to employ any local tailor, while purchasing the cloth at cost from the company:

GENERAL NOTICES TO EMPLOYEES

Standard uniforms will hereafter be made to conform with the following diagrams and specifications:

Uniform cloth, "Slater" No. 311, for suits, and No. 958, for overcoats, will be furnished by the company at cost, and may be obtained from the storekeeper on order, issued by superintendent of transportation. Failure to procure uniforms within twenty days after issuance of order on storekeeper will be sufficient cause for suspension.



The uniform for patrolmen will consist of a regulation suit made as per diagram *A*. Material to be of corduroy, as furnished by the storekeeper on order of line foreman or superintendent of construction and maintenance of way.

Employees can have uniforms made by any good tailor.

All uniforms must be inspected and approved by station masters or superintendent before being worn on duty.

The winter weight uniform cap for conductors, station masters and inspectors is of blue cloth, stiffened with haircloth, with straight peak and two gold uniform buttons; price $1.50.

Motorman's cap, same as above, but with vizor peak and two silver buttons; price $1.50.

PATTERNS FOR UNIFORMS—MILWAUKEE

The summer cap is of the same general description as the winter weight, but is covered with indigo blue duck; price $1.

The uniform cap for patrolmen is of corduroy to match uniform, yachting pattern, vizor peak, with two silver buttons; price $1

All uniform caps must bear the stamp of the maker, but employees are permitted to purchase their uniform caps from any reputable dealer.

Summer or winter caps may be used at pleasure of the wearer.

GEO. M. KUEMMERLEIN,
Superintendent of Transportation.

Approved, T. E. MITTEN,
General Superintendent Railway Department.

COAT (FIGURE A)

Coat for conductors, motormen, station-masters and inspectors:
Coat, ———. Double breasted, square corner sack, lapel collar. Velvet collar for station-masters and inspectors only.
Length, ———. To extend 4 ins. below the crotch seam, with five buttons on each side.
Edges, ———. Double stitch, ⅜ ins. wide.
Cuffs, ———. Three ins. deep, imitation stitch to match edge, two buttons.
Pockets (outside), ———. One breast, plain finish, two skirt, and two ticket, to be leather corded. (Recommended to be of leather or heavy linen duck, well stayed to prevent sagging).
Body lining, ———. Triple warp, black serge.
Sleeve lining, ———. Extra durable cotton stripe.
Cloth, ———. To be furnished by the company; 3½ yds. required for full suit.
Buttons, ———. To be furnished by the company; silver for motormen and patrolmen; gold for all others. (Recommend all buttons to be sewed firmly in place).

VEST (FIGURE B)

Vest, ———. No collar, six buttons, opening 13 ins. to first button.
Edges, ———. To correspond with coat.
Pockets (outside), ———. Two upper, two lower.
Lining, ———. Extra durable cotton twill.
Back, ———. Triple warp black serge.
Cloth, ———. To be furnished by the company.
Buttons, ———. To match diagram *A*.

TROUSERS

Two top or side pockets; two hip and one watch pocket. Cloth to be furnished by the company; 1⅜ yds. required.

OVERCOAT

Coat, ———. Double breasted lapel, five buttons on each side.
Length, ———. For motormen, 8 ins.; all others 6 ins. below the knee.
Collar, ———. For conductors and motormen, cloth collar, 5 to 6 ins. deep; station-masters and inspectors, velvet collar of ordinary depth.
Edges, ———. Same as diagram *A*.
Cuffs, ———. Same as diagram *A*.
Pockets (outside), ———. Two skirt, two ticket, two hand pockets; all leather corded. (Recommended to be of leather or heavy linen duck, well stayed to prevent sagging.)
Body lining, ———. Blue or black. (Recommend cassimere interlined with blanketing.)
Sleeve lining, ———. Best quality lusterine.
Cloth, ———. To be furnished by the company; 2¾ yds. required.
Buttons, ———. Same as diagram *A*.

In no direction can a railway company save money, or increase dividends more rapidly than by having its equipments thoroughly inspected by competent men, working systematically under intelligent direction. From paper at the Boston Convention, 1898.

NOTICE.

Papers and correspondence on all subjects of practical interest to our readers are cordially invited. Our columns are always open for the discussion of problems of operation, construction, engineering, accounting, finance and invention.

Special effort will be made to answer promptly, and without charge, any reasonable request for information which may be received from our readers and advertisers, answers being given through the columns of the JOURNAL *when of general interest, otherwise by letter.*

Street railway news and all information regarding changes of officers, new equipment, extensions, financial changes, etc., will be greatly appreciated for use in our Directory, our Financial Supplement, or our news columns.

All matters intended for publication in the current issues must be received at our office not later than the twenty-second of each month.

Address all communications to

The Street Railway Publishing Co.,
Beard Building, 120 Liberty Street, New York.

There have been so many important happenings in the transportation field during the past three months that it is difficult to keep pace with the progress of events, or to deal with them adequately within the limits of any publication. From all over the country and from foreign lands as well come reports of transportation projects which bid fair to tax home and foreign manufacturing facilities far beyond their capacities, and immediate expansion of these facilities seems a necessity of the most urgent kind, if grave disappointments on the part of customers are not to be realized. It appears probable that new realms are on the point of being conquered by mechanical motive powers, and that the horse will soon be displaced from cab and wagon service in our cities, and from many pleasure vehicles. New York city is to secure real rapid transit at last. Almost the entire transportation system of Brooklyn, surface and elevated, is now under one control, which may also secure the extensive steam railroad which controls the traffic of Long Island. Steam is to be as much a thing of the past in elevated railroading as are the horse and cable systems in street railroading. Foreign cities all over the world are yielding to a desire for better transportation facilities. Everywhere is found activity, energy, engineering enterprise, skill—and extraordinary indifference to investment costs if the ends to be achieved appear desirable.

Schedule speeds, car frequencies, operating expenses and net profits to stockholders are very closely related, and the street railway manager who appreciates this fact and makes a study of each of his lines with a view to increasing speeds and reducing frequencies, still giving due service to the public, will, all other things being equal, give a better account of his stewardship than will he who runs his cars slowly and too frequently. The advantage of high speeds is a double one. The same service can be given with less cars, and, therefore, less transportation wages; the power station cost per car mile is usually, within limits, somewhat reduced, and the gross receipts should be increased, owing to the greater inducement offered to the people to save time by riding. In more than one case, to our knowledge, the increase of car speeds has been the most potent influence in effecting the financial rehabilitation of street railway properties, turning a deficit into a comfortable surplus. In one instance, where higher speed was accompanied also by a longer time interval between cars, gross receipts per car mile were increased in two years about 33 per cent, with hardly 5 per cent increase in operating expenses, and the net earnings per car mile applicable to return on investment was increased 150 per cent. There is no doubt that not a few street railway companies have given to the people a service too frequent to be profitable to stockholders. Statistics show that in nearly every case where electricity has displaced horses, the immediate effects of the change have been a substantial reduction in the gross receipts per car mile. It is true that this has been brought about partly by the building of extensions in new territory and the consequent pulling down of averages, but it has also been caused in part by the great increase in the number of trips per hour and per day. We do not say that the service to the public should not have been bettered in this way—in many cases this betterment was a "franchise tax" in disguise—but a little less liberality with the people would quite surely have increased dividends.

The trustees of the new Massachusetts Electric Company, which controls thirty-one street railway and several electric lighting properties in Eastern Massachusetts, north, west and south of Boston, are fortunate in that the public resident in the territory served by their lines has not been educated to a too frequent car service, while the territory, being suburban in character, is such that high speeds—higher even than at present—can be easily obtained. A consolidation of this kind is more than likely to prove a decided public benefit, through reductions of fares, unification of policies, etc., while at the same time, in spite of the heavy overcapitalization which in these days

always accompanies a transaction of this kind, it seems possible to hope for materially increased profits. The Washington consolidation is a happy solution of a very difficult financial and administrative problem. The numerous suburban lines of Washington ought to be feeders of a central system, and not independent properties. The Chicago consolidation of the Yerkes properties is a simple and self-evident step, which would doubtless have been taken years ago had important franchise questions been settled. Capital has many times tried to effect a consolidation of the many street railway systems of St. Louis, and that it has finally been effected is a cause for congratulation, certainly to the people of St. Louis, and is, very likely, also for the capital invested. There is much talk of a consolidation of the surface and elevated railway systems of New York, but no rumors have thus far been verified, and there are, doubtless, serious obstacles in the way, but capital is, in these days, used to overcoming obstacles of almost every kind, and we should not be surprised at any time to learn that the apparently impossible has been accomplished.

The real and most serious difficulty which capital finds in carrying out these great consolidations is in obtaining the right men to handle the properties. There are hardly a dozen men in the country who are generally recognized in the industry as strong, forceful and thoroughly capable administrators of large street railway interests. These men are "placed," and cannot be shifted, for their associates will not let them go at any cost. A new list must be created from those who have hitherto successfully managed smaller street railway properties, or from the general business world, and the success of capital in fulfilling its promises to the investor will depend very largely upon the men to whom the operating responsibilities are given. The best managers are cheap at any price.

One feature of many of these new consolidations deserves special mention and thoughtful consideration. In Massachusetts the new consolidated company will own eighteen railway and electric lighting power stations. In Washington the two electric lighting companies of the city are consolidated with the railway companies, and plans are on foot for transmitting water power, and otherwise greatly improving the power station proposition. In New York the railway and lighting companies are largely owned in common, and further consolidations are in the air, while in many other cities the tendency is toward similar blending of interests. It is certain that through these consolidations electric power will be generated at much less cost in the future than in the past, and the utilization of that power will be far more general. The average load of an electric lighting station rarely exceeds 25 or 30 per cent of its maximum capacity, and the load factor of a railway station is hardly 10 per cent more. The mere union of these two interests will not in itself greatly improve matters, for the heavy loads of both lighting and railway service usually occur at about the same time of day, but the installation of large storage batteries in the power stations will make it possible to bring the load factor up to 60, 80, or even 100 per cent, provided that a market for the stored current can be found. That this market exists is a certainty. Consider, for example, the possibilities of the electric vehicle business—that infant industry which has just now cast off its swaddling clothes. One difficulty with electric vehicles heretofore has been their comparatively short radius of action. Before long—in Eastern Massachusetts, for example, with its thirty or forty power stations, located in every city, village and town of that great area, and with its magnificent roads—electric vehicles can take on a battery at Boston, exchange it for another at Lynn, for another at Gloucester, another at Newburyport, etc. In Washington, an electric cab and carriage service will doubtless be inaugurated with a similar plan of action, and in other cities wherever pavements are good the future for automobiles is assured. We must again point out to street railway managers how important it is that they should in some way obtain a hold upon this new and promising industry, which should immediately add to revenue, and at the same time act to prevent disastrous future competition.

A correspondent has written to us suggesting that the electric railway companies should publish maps of the different sections of the country showing their routes, so that persons, on pleasure bent, wishing to tour through any district, can lay their plans for traveling by electric cars. While the possible traffic to be secured in this way may seem to some to be rather small, there is no doubt that many electric railways, particularly those in the suburbs of large cities, could develop a considerable amount of pleasure riding by running through cars over connecting roads, especially where it is understood that such cars could be chartered to carry special parties. Among other territories where such traffic could be made popular the following might be mentioned: Around Boston, in the northern part of New York city, the Newark, Orange, Paterson region, the suburbs of Philadelphia, Chicago, and, in fact, of most all large cities where the suburban cars do not now run to the center of the city. The possibilities of following this plan in Eastern Massachusetts are discussed elsewhere in this issue, but while the treatment in that article is intended to cover a particular case, there seems to be no reason why the suggestions made are not equally pertinent to other districts

---

The Street Railway Purchase Plan in Detroit

It is impossible to deny to Governor Pingree and his political associates the merit of ingenuity and persistence, however much we may criticise their judgment and sincerity. They have devised a plan for securing municipal ownership of street railways in Detroit, which, though somewhat complicated, would certainly seem to accomplish the main object, which is to secure to the city the possible profits from street railway operation without imposing on it any of the risks and burdens of actual ownership. The plan in its elements is this.

1. The Street Railway Commission is to organize a new company, to which is to be transferred all of the present properties in the city. The new company is to be granted a consolidated thirty-year franchise for the operation of these properties, in place of the present franchises under which they are working, which expire from ten to twenty-five years hence. The new franchise provides for a general three-cent fare on all lines, and for special low priced labor and school tickets in addition.

2. The new company will join the old in mortgaging the present properties and future extensions (made by the new company) for the sum of $17,500,000, represented by fifty-year, 4 per cent gold bonds. As a further valuable asset behind these bonds, it is proposed that the city shall grant to the new company an additional "security franchise," so called, which provides that in the event of default in the interest or principal of the bonds, leading to foreclosure of the mortgage, the purchasers of the property under foreclosure shall have the right to operate the system during the remainder of the thirty-year period and for eighteen years beyond, upon terms and conditions nearly the same as those under which the present companies are now working, which include a five-cent fare with six tickets for twenty-five cents, with somewhat lower rates during the heavy hours of the day.

3. A sinking fund is to be established out of earnings sufficient to provide for the retirement of the bonds in fifty years.

4. Of the $17,500,000 of bonds thus secured by the present properties, the future extensions, and the security franchise, the old companies are to receive $16,800,000, and the new company is to retain $700,000 to provide for extensions, improvements, etc.

5. The stock of the new company is to be held by the Street Railway Commission as trustees, and if, later on, it is decided that the city can legally accept this stock for its treasury, it is to be formally turned over to it, but if not, then the city is to have the power, by a clause in the franchise granted to the new company, of so taxing the latter as to prevent it from making any profits whatever, i. e., the city can impose a tax equal to the entire net profits from operation, after paying interest on bonds and providing for the sinking fund.

It will be seen that the present street railway companies thus surrender control of their properties without a penny in cash, and without the benefit of the city's endorsement of the bonds. In other words, if the new company is unsuccessful, and the interest on the bonds is not paid, the bondholders can do nothing more than take back their property, but they will have as an additional asset a franchise terminating forty-eight years hence at remunerative rates of fare. The scheme is, as above stated, ingenious, plausible and not, perhaps, unfair to any of the interests involved. The experiment of three-cent fares can thus be carefully tried under most favorable conditions for its success and without putting the risk of the experiment upon private capital.

The method of arriving at an appraisal of the property upon which the $17,500,000 bond issue was based seems to be reasonably fair, though it is not, as is locally believed, unduly favorable to the street railway companies. In the first place, the physical assets of the present companies were appraised on the basis of "cost of duplication" by M. E. Cooley, J. D. Hawks, Gilbert Wilkes and others, all men of reputation and special ability in different departments. Their estimates coincided quite closely and led to the determination by the commission that the sum of $8,000,000 represented a fair valuation of the tangible assets. As auditor, E. B. Hutchinson, an expert accountant, went through the books for four years past, and determined that the true net earnings of the property last year were $805,000. As actuary, Prof. Edward W. Bemis, of the Kansas State Agricultural College, then determined the valuation of the franchises and fixed it at the sum of $8,478,564. Prof. Bemis arrived at this sum in the following way.

1. He first scaled down last year's earnings from the auditor's figures, $805,000 to the sum of $750,000, the difference being accounted for, as he claimed, by probably insufficient charges for depreciation.

2. He next assumed an average increase in net earning power of 4 per cent per annum during the remainder of the franchise life of the different properties. This figure was considerably less than the increases of the last few years, but it was deemed by him, as protector of the city's interests, conservative.

3. Having obtained in this way an estimated net revenue for each of the remaining years during which the franchises were to run, he deducted from this revenue, interest at 4 per cent on the cost of the tangible assets, thereby obtaining for each year what he calls the "monopoly earnings," or earnings due to the possession of a franchise over and above the fair return on the actual capital investment.

5. He then discounts these earnings, at 4 per cent, in order to find their present value.

6. The sum of the present values of the estimated "monopoly earnings" of all the years for which the present franchises are to run, becomes, therefore, according to his theory, the value of those franchises above that of the tangible assets.

The effect of a valuation theory of this kind is, of course, to capitalize future earnings, and, temporarily to increase the interest and sinking fund requirements of the new company. This fact is recognized by Prof. Bemis, and he recommends that the sinking fund be created in such a way as to follow the city's ability to pay, the payments of the first few years being less than those of later ones.

The whole investigation of the Detroit situation has been carefully made, and is, in principle, scientifically correct, but that fact is not fully recognized by the people, who see in the plan only the price which the street railway companies are to get for their properties, forgetting first that a 4 per cent bond of that character will quite surely have to be sold at a considerable discount, and second, that the 4 per cent rate of increase in net earnings assumed by Prof. Bemis is probably considerably less than would be realized by the present companies were they to continue in the possession of their properties.

The Street Railway Commission in Detroit proposed to refer the whole matter of purchase to the people for action, but on June 27 the whole question was laid upon the shelf by a unanimous vote of the common council sustaining the action of its committee on streets and ordinances in unanimously declining to recommend any steps toward city ownership at this time, in view of the facts, first, that no bargain could be made with the railways if three-cent instead of five-cent fares are specified in the security franchise; second, that no legal authority can be found for obtaining a special vote of the people on the subject; and, third, that litigation seems assured if any favorable action should be taken.

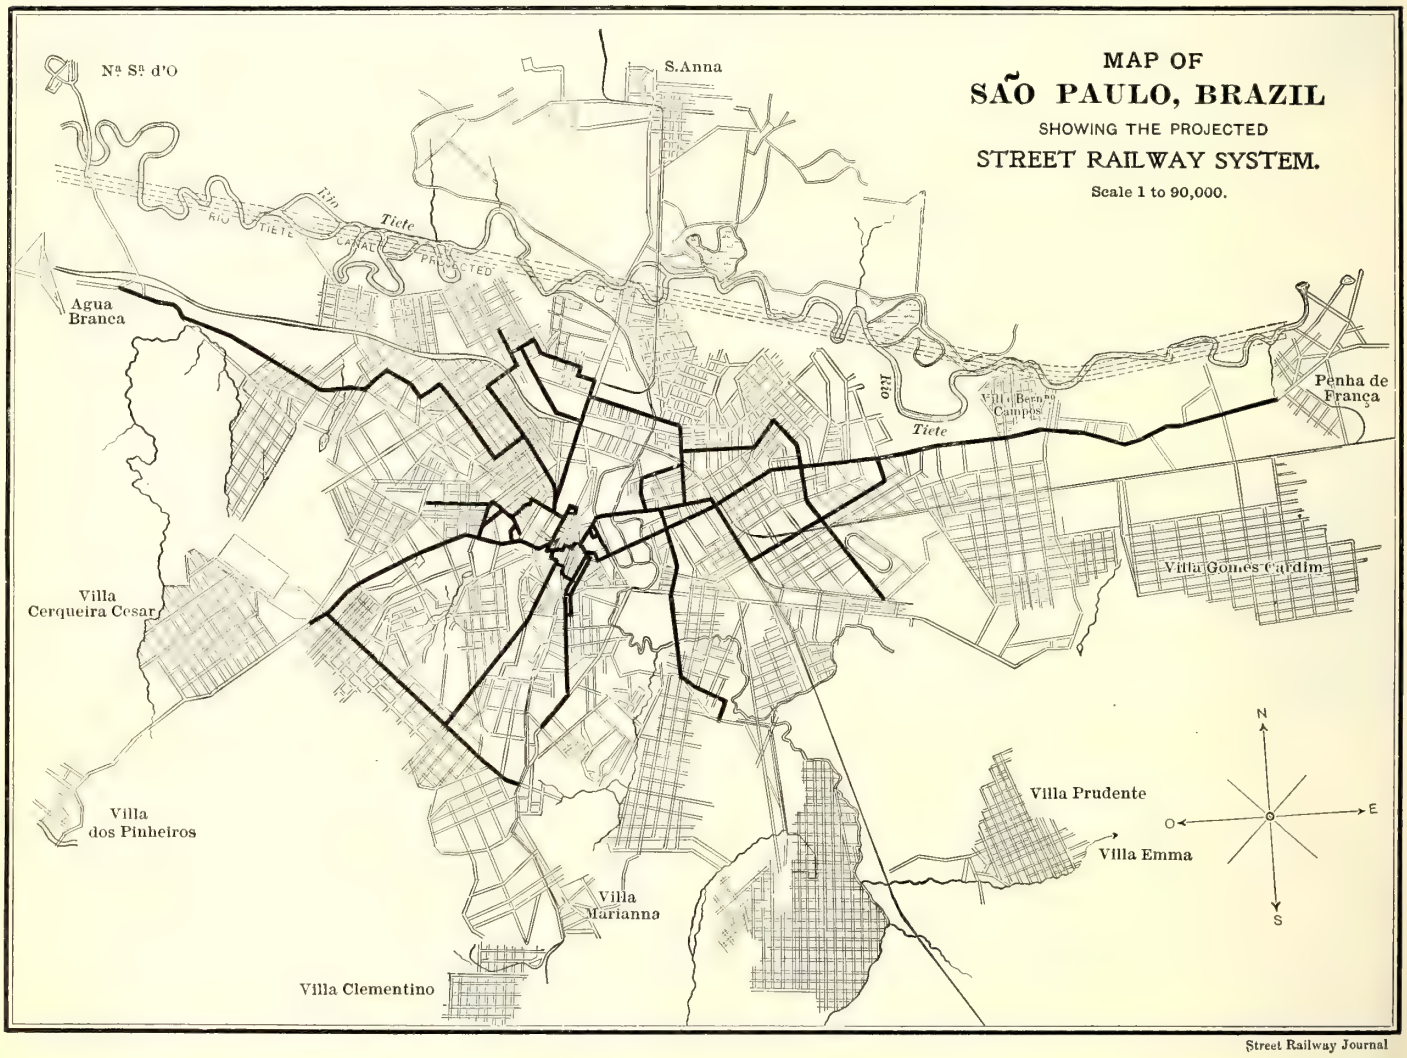
Too much care cannot be given to the sizing and alignment of wheels and the pressure with which they are forced on the axle. At least 50 per cent. of the wheel removals throughout the country are caused by broken or sharp flanges, or a broken wheel. From paper at the Boston Convention, 1898.

The New Railway, Light and Power Enterprise in Sao Paulo, Brazil

Comparatively few North Americans know that in the southern part of Brazil, hardly 300 miles southwest of Rio de Janeiro, lies one of the richest and most rapidly growing cities of South America, the capital of the State of Sao Paulo, and most advantageously located as regards climate, elevation, railway connections and seaport facilities. The city of Sao Paulo is situated about 40 miles from the seacoast, directly under the Tropic of Capricorn, 23½ degs. south of the Equator. At a point about 5 miles from the ocean hills rise abruptly to the height of 2000 ft., and from this point a table land extends inland for many miles. Sao Paulo is one of the highest points on this table land, its elevation being 2500 ft. above sea level. The climate is, for a tropical country, cool, bracing and healthful, and is not characterized by that depressing tropical humidity which is felt in the seacoast cities of Brazil. The latest estimates place the population at not less than 250,000, the growth having been extremely rapid during the past ten years.

BIRD'S-EYE VIEW OF SAO PAULO, BRAZIL

VIEWS IN THE CITY OF SAO PAULO



It is to this city that the attention of a number of New York and Canadian capitalists has been directed for some time, with the result that a syndicate has been formed, consisting of F. S. Pearson, chief engineer of the Metropol-

itan Street Railway Company, of New York; William McKenzie, who is largely interested in many street railway properties of Canada; B. F. Pearson, of Halifax, and others, to develop the street railway, light and power interests of Sao Paulo. Franchises have been obtained for street railway lines covering all desirable routes in the city, including a few miles of street now traversed by an antediluvian mule railway, which has been in existence for some years. R. C. Brown, whose management of the Halifax (N. S.) property was such as to win him the entire confidence of its owners, Messrs. Pearson, McKenzie and others, sailed on June 5 for Sao Paulo with a large consignment of electric railway apparatus, and will be in full charge of construction, equipment and, temporarily, of the operation of the system. He is accompanied by F. S. Pearson, who will determine the main outlines of the installation, locate power stations, etc.

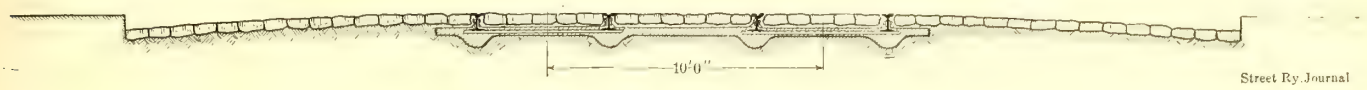
The State of Sao Paulo is the principal coffe producing State of Brazil, and is one of the leading and most populous in the entire republic, the production of coffee being a very profitable industry in this climate and under the conditions found here. Forty miles away from the city lies its seaport town, Santos, which gives the name to the coffee produced in the State. The manufacturing industries connected with the coffee trade and supplies for the State have been established in the city of Sao Paulo, which has thus become quite a manufacturing center. The city is obliged to be largely self-supporting, as it is 240 miles away from Rio de Janeiro, and is connected with a railroad running through a hilly district not favorable for the transportation of freight.

The city is quite cosmopolitan, having about 70,000 Italians, and a large number of German, French, English and American residents, and as a result of this foreign mixture there is less opposition to the introduction of foreign customs and enterprise than is found with the people of the Portuguese and Spanish towns of South America. Many of the local enterprises, including the Sao Paulo Steam Railroad Company, the mule tramway company and the gas company, are all of English origin, though a considerable portion of their stock is held locally.

The "old town" of Sao Paulo, which was founded in 1554 by the Jesuits, was built upon a bluff, the sides of which were quite steep. This part of the city is of small extent, but in it are the chief business houses, especially of the retail dealers. The streets are narrow and crooked, but are well paved, and the sidewalks are kept in good

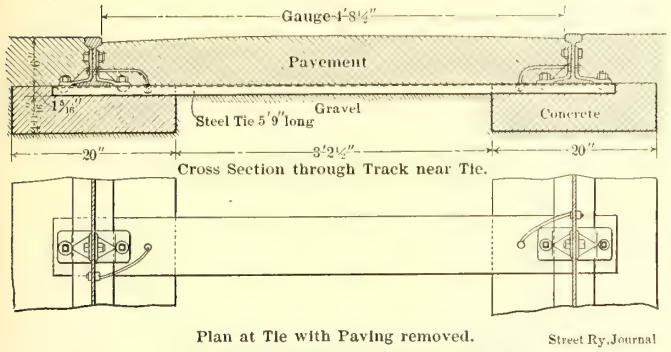
Street Railway Journal

order. Generally speaking, most of them are not, even in this old town, any more hilly than in the average city of the North, but two or three of the approaches thereto are upon streets which are wholly inaccessible to teams or cars, while others have considerable grades, running as high as 9 per cent, though these are short.



Radiating from the side of the old town, the city has grown outwards quite uniformly, although the development has perhaps been more rapid to the northwest. On the west side, to a distance of 1½ miles from the old town, and considerably above its level, are found some of the finest residences of the city. These districts have, however, very poor and inconvenient transportation service into the center of the city. Northwest of the old city, and quite near it, are thickly populated districts, one of which is so densely populated that electric lines will be well patronized for short distance riding. The present mule

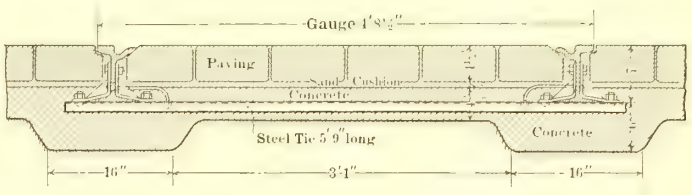
tramway lines are so circuitous that time can often be saved by walking.



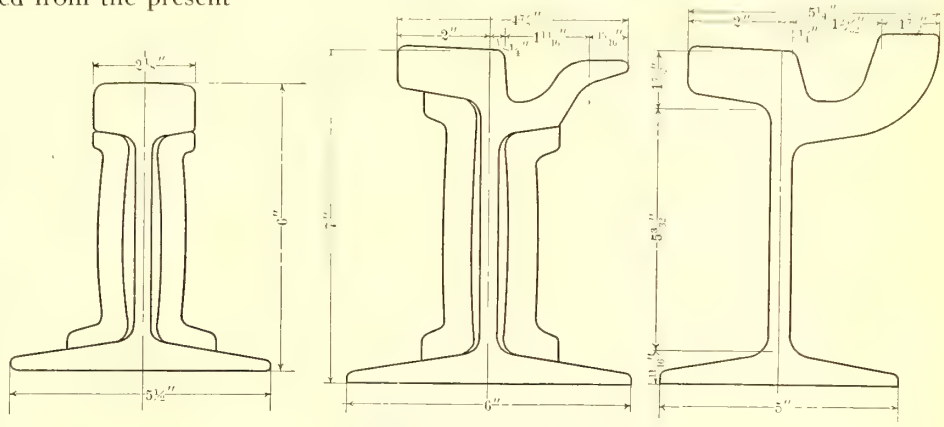
The Pearson-McKenzie syndicate has obtained a concession for the lines shown on the accompanying map. These are laid out in such a way as to give the whole city a good service, but it is not believed that the development of the system will stop with the completion of these lines, for there are desirable suburbs to be reached.

Coal in Sao Paulo sells for $10 per ton, and wood is equally costly. As a consequence, the price of gas and electric lighting is high, and none of the city lighting is as yet done by electricity. Five thousand commercial incandescent lamps are, however, supplied from the present station. The electric light service begins at sundown and, except for a few large customers, extends only until ten o'clock in the evening.

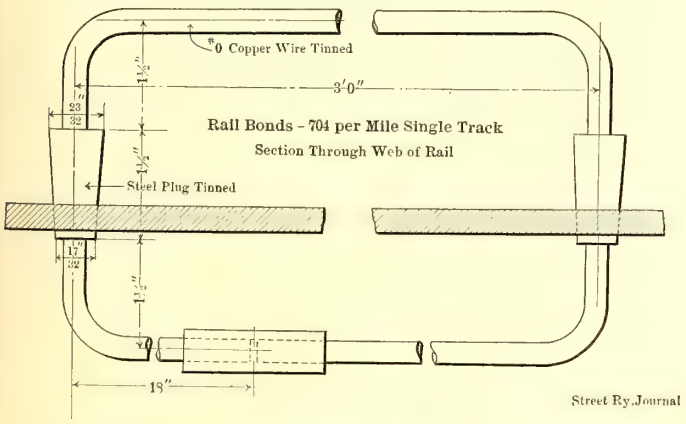
About 20 miles west of the city of Sao Paulo is the only large water power near the city, with a probable minimum supply of 10,000 h.p. to 20,000 h.p. This has been secured by the Pearson-McKenzie syndicate, which intends developing power and transmitting it to Sao Paulo for furnishing the lighting, railway and power service. The introduction of cheap power into a city where steam power at present costs from $100 to $150 per annum will mean a great deal to the industries of Sao Paulo, and to the lighting and railway enterprise. The right to build a transmission line has been obtained, and this line will pass through the town of Augua Branca, where there are at present several factories.



SECTION OF ROADWAY



SECTION AND PLAN AT TIE OF T-RAIL CONSTRUCTION



The new syndicate has obtained the government approval for a type of street car, which is almost an exact duplicate of the Broadway (N. Y.) car, and also for a modification of the rail section to the "Trilby" section shown in the accompanying drawing. At present there has been shipped to Sao Paulo 10 miles of track, with necessary ties and other railroad iron, furnished by the Pennsylvania Steel Company; fifteen Brill cars, Broadway pattern; two 225-kw. General Electric generators for direct connection with the Robb Engineering Company's engines, and Cahall boilers. By the end of the year it is expected that 35 miles of track and seventy-five cars will be in Sao Paulo, and within a short time thereafter the temporary steam power station, now building, with apparatus described above, will be replaced by power electrically transmitted from the waterfalls by the three-phase system. At this waterfalls a brick and cement dam, 40 ft. high and 400 ft. long, will be constructed.

SECTION OF GIRDER RAIL CONSTRUCTION

SECTIONS OF STANDARD RAILS

METHOD OF BONDING

The method of track construction used by the company is illustrated in the accompanying engravings. The standard 7-in. girder rail, which is used for city streets, weighs 90 lbs. per yard and is mounted on steel ties spaced every 10 ft. The ties are set in concrete, the latter being carried a distance of 4 11-16 ins. below the base of the rail. The rails are connected with the ties by clips, and are bonded to them, making a cross connection. The joints are also bonded by the Anderson West End bond, illustrated herewith. The guard rail weighs 110 lbs. per yard, and the T-rail for suburban service 62 lbs. per yard.

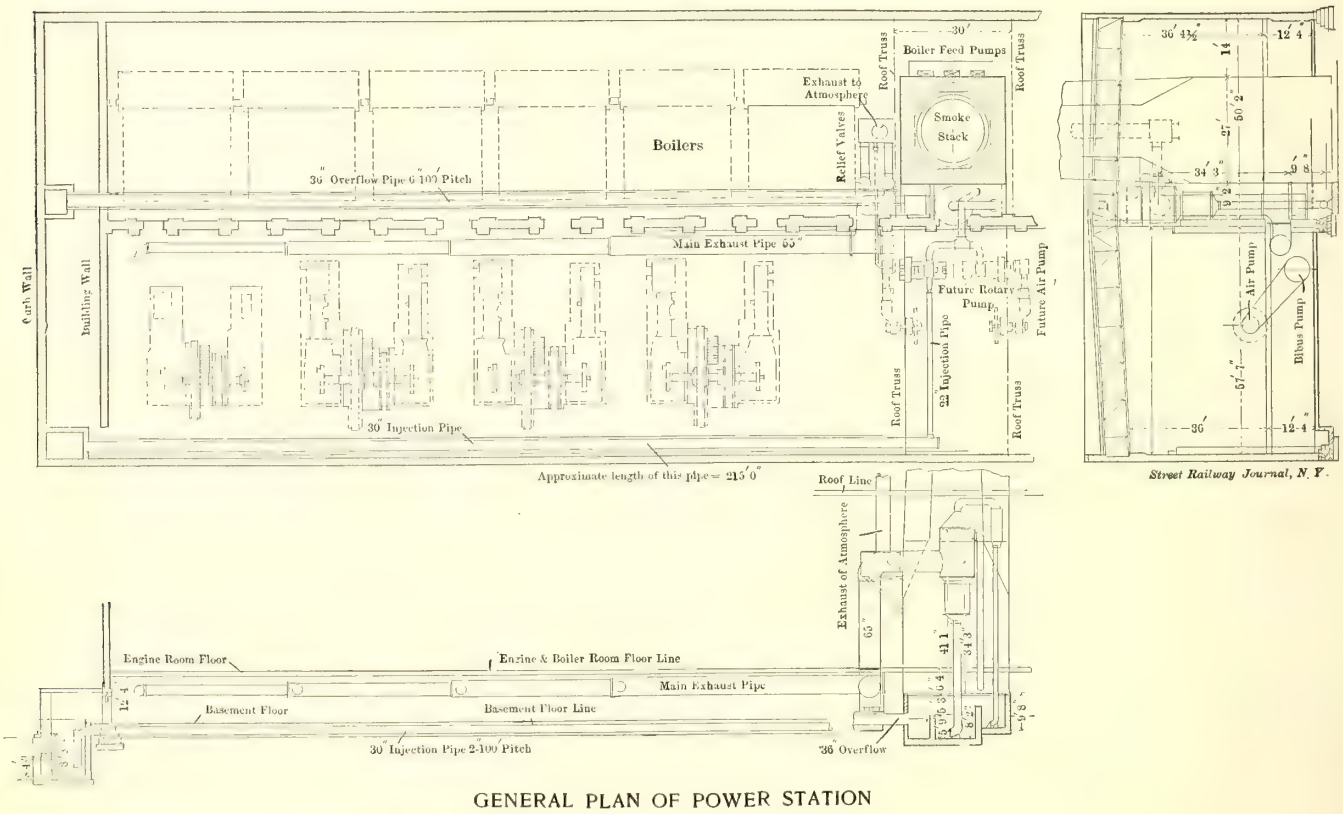
Ash seems to be most universally used in post and light framing of cars. This is probably due to the difficulty in securing the grade of oak necessary; the lighter the weight of the ash the greater ease with which it is worked. In spite of these difficulties, oak is far preferable, being stronger and more elastic, and will give a far longer life. From paper at the Boston Convention, 1898.

Power Station of the Northwestern Elevated Railway of Chicago

This plant, which is one of the large power stations in Chicago, is nearing completion. It is located on Fullerton Avenue, 3000 ft. west of the elevated structure, and about midway between the ends of the line. The outside dimensions are 255 ft. x 112 ft., the engine room being 57 ft. 7 ins. wide, and the boiler room 50 ft. 2 ins.

The building is of brick, with concrete roof and checkered steel plate floors. The basement, extending under both engine and boiler rooms, is 12 ft. 4 ins. high, with concrete floor, finished in granitoid. The engine room basement contains all steam and exhaust pipes, separators, receivers, as well as the electric cables to and from the switchboard. The boiler room basement contains the smoke flues and the entire system of feed and blow-off piping, ash conveyors, etc. The boiler feed pumps are also located in the basement, on the side of the chimney.

The latter is a prominent feature of the building. It has a 16-ft. flue, and the top is 203 ft. above the street level. It is 27 ft. square at the base, and rests on a foundation of piling, driven 30 in. centers. These piles carry a concrete footing 31 ft. square and 5 ft. thick.



The plant will contain three engine and generator units of 1500 kw. capacity, and one of 750 kw. The engines are cross compound, of the Allis-Corliss type, and are direct connected to Siemens & Halske generators with the internal armatures. The cylinders of the 2000-h.p. machines are 30 ins. and 60 ins. x 60 ins. stroke. Those of the 1000-h.p. machine are 23 ins. and 46 ins. x 48 ins. stroke. The diameters of the flywheels on the two engines are 25 ft. and 20 ft., operating at 75 r.p.m. and 80 r.p.m., respectively.

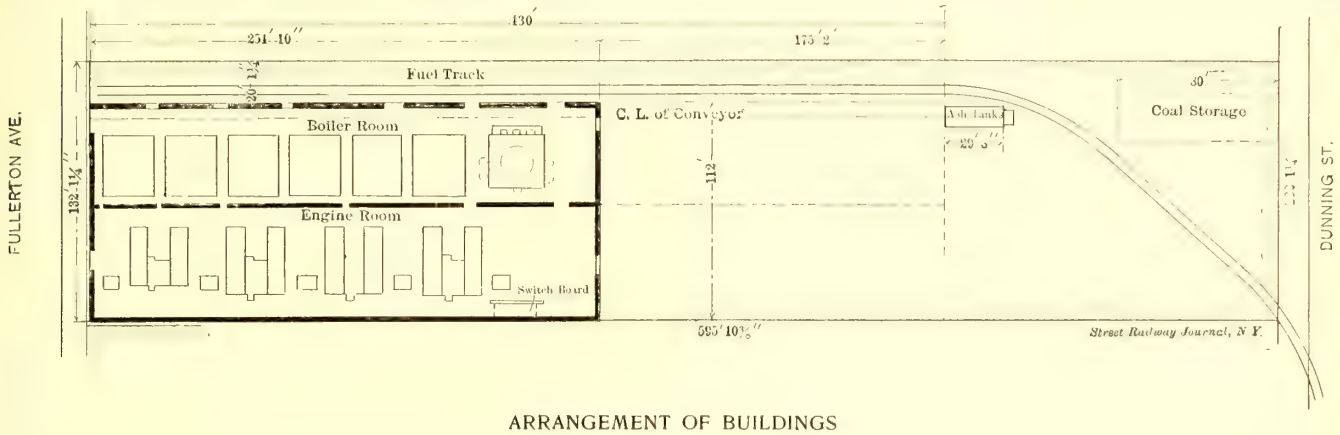
The plant will contain twelve batteries of Babcock & Wilcox water tube boilers, set in batteries of two boilers, and equipped with twenty-four Murphy automatic smokeless furnaces. In connection with the furnaces there will be storage bins, conveyors and chutes, which will deliver the coal into magazines, from which it will be fed automatically into the furnaces. The conveyor system will be of the gravity bucket type, and will be so arranged that the buckets will receive the ashes in the basement and carry them to the ash bins outside of the building. The coal, after going through the cracker, will either be distributed by the conveyors along the length of the outside storage bin, or else distributed in bins above the furnaces.

The main steam header, to which all boilers are connected, is located in the boiler room above the boilers, and is made of 28-in. lap-welded wrought iron pipe, with the flanges welded on. The header is made in three sections, each section being connected by four 8-in. "U"-shape steel pipes. A 6-in. separate header is provided for the auxiliary machinery. The maximum working steam pressure will be 160 lbs. per sq. in.

All the live steam valves are extra heavy-ribbed, bronze-seated gate valves of the Chapman manufacture.

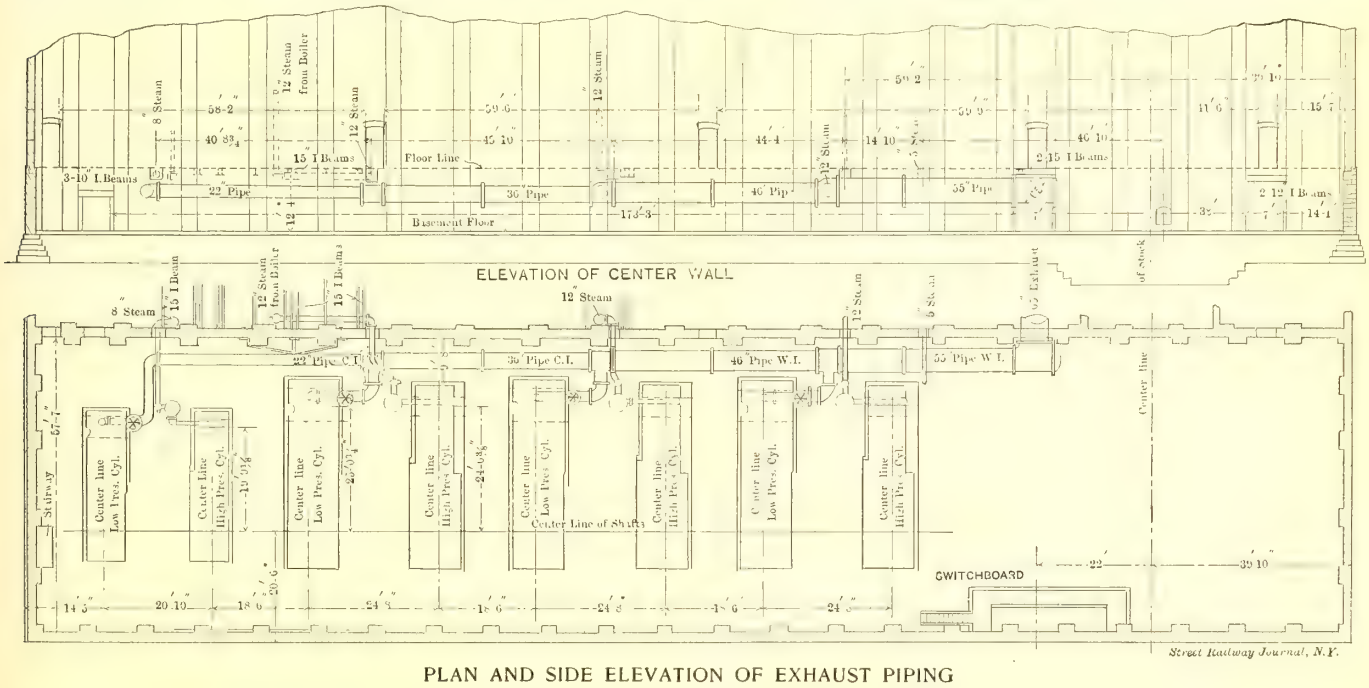
The boiler feed water will be supplied by three vertical duplex feed pumps of the admiralty type, manufactured by Henry R. Worthington Company. The water, before entering the boilers will pass through two heaters of the Berryman type, with a capacity of 2000 h.p. each. All exhaust steam from the auxiliary machinery is taken into these heaters.

GENERAL PLAN OF POWER STATION



In place of the usual arrangement of an independent condenser for each engine in the power house a central condenser of the Weiss counter-current type, built by the Southwark Foundry & Machine Company, is being installed by Edward M. Hagar & Co., the Western agents for this device, to condense the steam from all the engines in the power house. The condenser vessel being installed has a capacity sufficient to take care of the ultimate capacity of the station, that is, 14,000 h.p. The auxiliary machinery, consisting of a steam engine driving tandem

The city has a 12-ft. brick tunnel from Lake Michigan, which flushes the north branch of the Chicago River. This tunnel runs in Fullerton Avenue directly in front of the power house, and arrangements have been made with the city whereby all water used in the station for condensation and other purposes is supplied from this tunnel through a 30-in. pipe.



a dry air pump and belted to a Bibus pump of the rotary type, is of sufficient capacity to take care of the present installation of engines, which have a nominal power of 7000 h.p.

The air pump is an improved type of air compressor, with positive and automatic valve motion, working absolutely free from water. The circulating pump is of the positive type, of high efficiency, and both this and the air pump are driven by an economical engine provided with a capacity regulator. This circulating pump only handles the cold injection water, the hot water passing out automatically through a barometric column, or so-called water leg.

Many advantages are obtained by the use of this central condenser, and it is said that the amount of power required to drive the condensing machinery is only a fraction of that required by the usual jet condensers. It is also claimed that this condenser uses only one-half to two-thirds the amount of cooling water necessary for a jet or surface condenser, and again, the height that the condensing water has to be lifted is not so great in the Weiss condenser as it is in an ordinary condenser using a wet air pump, there being a "balance" due to the height of the water in the barometric tube or water leg. The hot well of this condenser is hotter than with any other, as the temperature of the overflow can be the same as that of the exhaust steam. In other words, it obtains without cost the same effect as would be produced by a feed water heater in the exhaust pipe. For these reasons, and on account of the simplicity of its construction and the positive regulation of the amount of the condenser water, the system seems particularly adapted for use with fluctuating loads and for central condensing plants. The reliability of the condenser comes from the fact that there are no valves of any kind, of contracted area or small openings for the air or water to pass through, which can become clogged or congested, causing a dropping of the vacuum. At the same time the amount of water fed to the condenser is automatically regulated by the positive displacement rotary pump, which is driven by the air pump engine. In the usual condenser a sudden increase in the load, or a leak, lessens the vacuum, which in turn reduces the quantity of water, causing a still poorer vacuum; whereas in the Weiss system the water is pumped in entirely independent of the vacuum. An increase of load, however sudden or severe, does nothing except slightly lessen the vacuum. A back flow of water from the condenser into the main engines can never occur, because the water flows out freely by gravity through the water leg, which is always of liberal size. The exhaust piping in a central plant using a Weiss system is also simplified, and a large number of cross-connections, gate and free-exhaust valves are dispensed with, as the exhaust main is run through the plant, and all engines attached to it. A free-exhaust valve located at the condenser vessel will lead the steam to the atmosphere should it be necessary at any time to operate the station non-condensing. The ability to maintain a good vacuum at the engines situated a distance from the

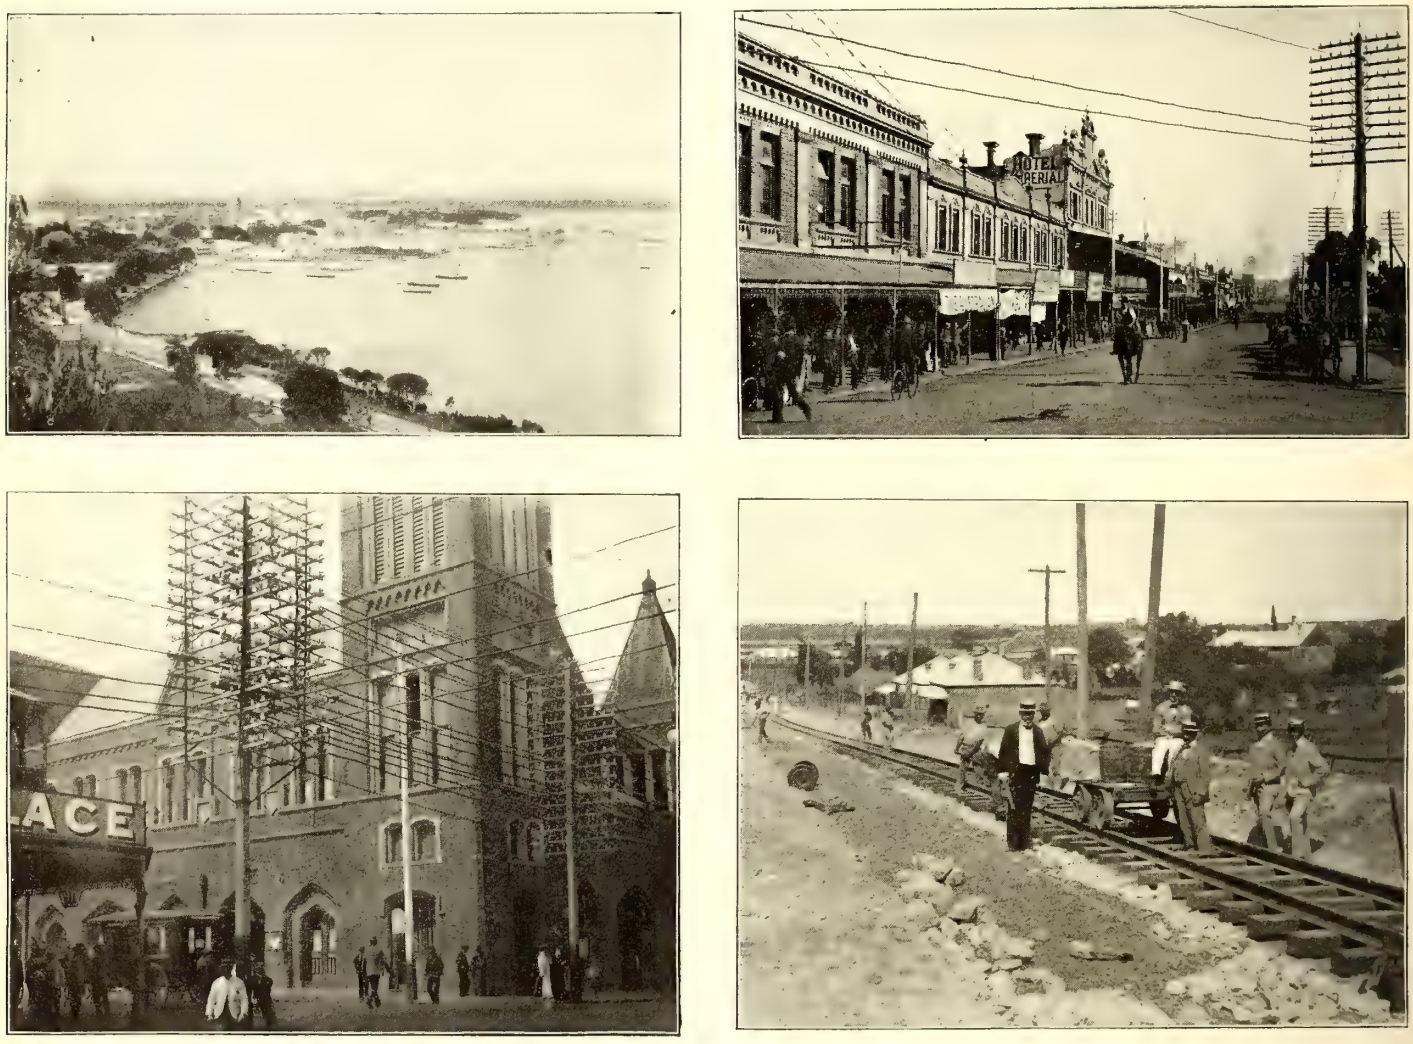
ARRANGEMENT OF BUILDINGS

PLAN AND SIDE ELEVATION OF EXHAUST PIPING

condenser comes from the fact that the air is removed separately from the water, thus taking care of any moderate leaks in the main exhaust pipe.

The switchboard panels are the General Electric Company's standard railway type. The generator panels are on the main floor, and the feeder panels on a gallery.

James R. Chapman is the chief engineer, and Z. E. Knapp, engineer in charge of the work.



New Plant at Perth, Australia

The construction of a new complete steam and electrical plant for the Perth Tramways, Ltd., Perth, Western Australia, is progressing rapidly. The equipment for the station will be as follows: Two 250-h.p. Babcock & Wilcox boilers, with wrought headers; two 325-h.p. tandem compound engines built by the Robb Engineering Company, of Amherst, N. S.; two outside packed single cylinder double plunger feed pumps, each capable of feeding 500-h.p. of boilers; two 225-kw. direct connected railway generators, manufactured by the General Electric Company, together with switchboard and accessories. A complete system of steam exhaust feed water and drip piping will be installed, and all fittings in high pressure piping will be made of gun iron; all joints are of the Van Stone type, and each boiler is equipped with a No. 12½ Hayden & Derby double tube lifting injector. All the piping in the plant will be covered by H. W. Johns fire-felt covering; Chapman valves will be used.

The steel roof trusses and purlins for the car barn were furnished by E. B. Gumaer, Jersey City, and the corrugated roof covering was furnished by McCullough Iron Company, of Wilmington, Del. Ten new cars have been ordered from the J. G. Brill Company, of Philadelphia. These will be single truck, 18-ft. bodies, with cross seats and center aisle, and will be mounted on Brill 21-E trucks.

The 9-in. girder rail, with fittings for 2 miles of the system, was furnished by the Pennsylvania Steel Company. The remainder of the rails were shipped from Belgium. The special work of hard center construction was furnished by William Wharton, Jr. & Company, of Philadelphia.

J. G. White & Company, of New York, prepared the plans for the foundations and buildings, and all detailed drawings for temporary power house, car barn and power plant, and acted as the general purchasing agents in the United States for the London syndicate owning the tramways. W. E. Cooke, representing the London owners, has complete engineering supervision of the erection of the new plant.

VIEWS IN PERTH

Milford, Attleboro & Woonsocket Street Railway

The Milford, Attleboro & Woonsocket Street Railroad Company is building an important link, 33 miles in length, which will connect the terminals of ten electric railroads and pass by the depots of seven steam railroads. Upon the route are five well-known pleasure resorts, including Pearl Lake, where a natural amphitheater seats 3000 persons. One section of the line connects Hopkinton, Bellingham, Franklin, Wrentham and Attleboro. Another

section connects Caryville with Bellingham, Blackstone and Woonsocket.

The company will have two power stations. One will be equipped with two 250-kw. Westinghouse "engine type" generators, direct connected to steam engines working at 120 r.p.m. The other will contain two 325-kw. Westinghouse direct connected generators, working at 100 r.p.m Thirty-two new cars are being built for the service; one-half will be single truck, with two 30-h.p. Westinghouse railway motors, and the other half will be mounted on double trucks, and equipped with four 30-h.p. Westinghouse railway motors. The larger cars will be capable of maintaining a speed of 30 miles an hour.

History of the Cleveland Strike

The history of the strike of the Cleveland Electric Railway Company's employees is largely told by the following communications which have passed between the company and the men.

On June 9, the day before the strike was actually declared, the company sent out a circular letter to each of its employees at their home addresses, reading as follows:

To the employees of the Cleveland Electric Railway Company:

The company having learned that for the first time in many years dissatisfaction exists among its employees, which it believes is very largely due to mutual misunderstandings, desires to make a plain statement of its position, so that entire harmony may be secured.

It may be true that in the management of so large a system of roads, involving so many details, conditions at times exist which ought, for mutual benefit, to be modified, and the company stands ready to make every concession for the comfort and benefit of its employees which can reasonably be asked, or which can be granted consistently with the proper performance of its public duties.

This company is a common carrier, and has the entire burden of responsibility for the safe and proper carriage of its passengers. It cannot free itself from this burden, nor can it lawfully leave to others who have not this responsibility any direction or control in matters affecting the efficiency of its service.

It will be readily conceded that the company must make and rigidly enforce all rules which are necessary for the safety and comfort of its passengers. The company, however, needs and desires the hearty co-operation of its employees in the enforcement of rules, and stands ready to make modifications in its present rules, if any of them are unjust to its employees. Its attention has, however, only been called to three or four specific objections, such as the pay of men working short hours, lay-over time at end of routes and swing runs. The schedules at present in force were adopted after careful consideration, with a view to the most efficient transportation of passengers upon its cars. The forms of the schedules have not been changed, nor are there additional swing runs therein. The company has so far been unable to find any way in which to handle the increased traffic of morning and evening except by means of swing runs. It, however, desires to use no more runs of this character than are absolutely necessary, and it is possible that a readjustment of the time table may do away with some objectionable runs and modify the speed of others, as well as provide suitable lay-over time. In so far as this can be done, the company will make the necessary changes, if any feasible plan can be found which will obviate these difficulties.

With reference to wages of men working short hours, the distribution of extra runs and the pay therefor, the company will be glad at any time to receive any committee of its own employees for the purpose of considering these questions, as well as the other complaints which have led to the present situation, so that, so far as such complaints are reasonable, they may be corrected. If the company and its employees are unable to agree as to the reasonableness of such complaints and the proper redress thereof, the company stands ready to submit the same to disinterested arbitrators, to be chosen in the usual way.

By order of the board of directors.

The Cleveland Electric Railway Company,
H. A. EVERETT, President,
R. A. HARMAN, Secretary.

Cleveland, Ohio, June 8, 1899.

On June 10, the strike was formally declared, a strike in its essence one for the recognition of the street railway employees' union, and a demand that the company should employ only union men, and should compel all their present employees to become members of the union immediately.

On the afternoon of June 11, the following resolution was adopted by the board of directors of the company:

Whereas, The Cleveland Electric Railway Company has exhausted every effort to come to an amicable understanding with its employees; and

Whereas, In spite of such efforts its employees have inaugurated a strike upon its lines and have refused longer to perform their duties. Now, therefore, be it

RESOLVED, First, that all of the company's employees who desire to continue in its service are hereby required to report for duty at their respective stations on Monday morning, June 12, 1899, at 7 o'clock, and that the employment of those who do not so report be terminated.

Second. That the superintendent of the company post a copy of this resolution upon the company's bulletin boards at its different stations, and that the resolution be also published in the daily newspapers of the city of Cleveland, so that all employees have notice thereof.

By order of the board of directors.

R. A. HARMAN, Secretary.

On June 11, the State Board of Arbitration met in Cleveland and attempted to bring about a reconciliation of the differences between the parties, but after a conference with the labor leaders and President Everett, the following letter was received by the Board of Arbitration:

June 12, 1899.

Honorable State Board of Arbitration:

Dear Sirs—At a meeting of the board of directors just held, the following resolution, offered by Mr. Stanley and seconded by Mr. Andrews, was unanimously adopted, viz.:

RESOLVED, That the differences between the Cleveland Electric Railway Company and its former employees have substantially narrowed down to the proposition, upon which the company must stand, that it must hire and discharge men without the dictation of anybody. As already stated, it does not attempt, nor will it attempt, to dictate to its employees whether they shall belong to a union or not. It will not require them to join, nor will it discharge them for joining or refusing to join, at their pleasure. The company must reserve to itself the right to treat directly with its own men, to hire new ones as the needs of its service require, and to discharge inefficient men without accounting to anybody except to its directors.

Entertaining these views, it must respectfully decline to submit these questions to arbitration. Very respectfully,

R. A. HARMAN, Secretary.

The strikers' appeal to the public, issued on June 12, is as follows:

To the Citizens of Cleveland:

We, the undersigned employees of the Cleveland Electric Railway Company, earnestly request every citizen to co-operate with us in our time of need, to help us settle our differences between said company and its employees, as they are shipping in men from other cities by the carloads to take our places by misrepresentation, telling these men through agencies in other cities there is no trouble here, and as we are not asking anything but citizens' rights in our public streets, we want slower time, so as not to endanger the lives of the people of our community.

We have tried every means in our power to live up to said company's rules and protect our families and citizens, and found it impossible to do under existing rules and schedules, so we earnestly urge you to assist us in our trouble.

We have met with a flat refusal to treat with us in any manner, except as individuals. Now, as from past experience we have found that their verbal agreements have never been lived up to, we have determined among ourselves to accept nothing but a recognition of our association, believing that in union there is strength. This is not a matter of wages, but one of principle, and that principle is the right to demand humane treatment from the Cleveland Electric Railway Company.

We request all citizens and taxpayers to be present at the meeting of our City Council to-night, to urge upon that honorable body the immediate settlement of the existing differences. Signed

HARRY S. BRYAN, President,
R. S. THOMPSON, Secretary.

On June 17, the strikers issued this further appeal to the public:

To the Citizens of Cleveland:

We, the employees of the Big Consolidated, do earnestly petition the citizens of Cleveland to refrain from riding on the cars of the Big Consolidated lines which are now being operated by workmen imported from nearly every city in the Union. We claim they cannot give as satisfactory service as can be given by members of our union, who are citizens of Cleveland, and who have families whose whole interests lie in the betterment of one of the grandest cities in the country. Therefore, we once more appeal to every citizen who has the love of his flag, city and family at heart to help win an honorable battle for right and justice.

Respectfully submitted,

Executive Board, A. A. of S. R. E. of A.

The strike collapsed a day or two later, the strikers intimating their willingness to give up recognition of the union. On June 21, the following offer was made by President Everett to the committee of the Common Council, specially appointed to deal with the matter of the strike:

The memorandum proposal of the committee composed of late employees of this company, submitted by your honorable committee to the company, has been considered by the company's board of directors, and by order of said board the company begs to make the following statement to your committee:

The first and most difficult question presented is that of the status of the company's former employees. This company cannot restore the status quo existing previous to the strike, because its men left their employment and refused to operate its cars, and being required by law and its contract with the United States Government and the city of Cleveland to operate the same, it employed other operatives, who have remained loyal during this trouble. In order to secure the services of these men the company was obliged to assure them regular employment, and it cannot honorably or legally violate those contracts and discharge these men. The company has, however, employed no more than from time to time have been absolutely necessary to operate such parts of its lines as it could safely operate, but has refrained from employing new men more rapidly with the hope and in the expectation that its late employees would re-enter its service. The only thing the company can do is to re-employ at once, without regard as to whether they are union men or not, as many of its former employees as its business requires, which will to-day be at least 60 per cent of the entire number, and as many more as possible, distributing the runs among the present employees and of those thus re-employed as equitably and fairly as possible, taking into account the rights of each. Beyond this, as additional men are needed in the company's service, its former employees will have the preference at all times.

In this re-employment two things must, of course, be understood: First, the service of the former employees with the company's present employees must be loyal, and the latter must not be subject to annoyance or abuse by the former; second, the company reserves to itself the right not to re-employ any of its former employees who have committed unlawful acts during the strike. It is not necessary to discuss any other matters of difference until some agreement is reached upon this most important proposition.

This proposition was refused by the strikers, who demanded that all employees except those who had been actually detected in destroying property be taken back, that all disputes between the company and its employees on questions of schedules or wages of men should be determined between the company and a committee of employees, and that all their questions should be determined by outside arbitrators, if the joint committee cannot agree. The strikers formally receded from their main original contention that union employees only should be employed.

On June 25, the strike committee of the Common Council reported as follows:

The council committee appointed by the City Council to aid in adjusting, if possible, the strike between the Cleveland Electric Railway Company and its late employees, can to-day obtain such an adjustment upon the following terms, to which the said company on its part assents:

1. The restoration of former schedules to stand, as publicly announced to the city authorities.

2. Upon questions of wages of the men working short hours, the distribution of extra runs and the pay therefor, as well as upon other grievances, the company will receive a committee of its own employees for the purpose of considering the same, and if unable to reach a conclusion with such employees or their committee as to the reasonableness thereof, the company will submit these differences to disinterested arbitrators, to be chosen in the usual way.

3. In order that the men in the company's employ may have a proper sense of security in their employment, the company shall not discharge any man except for cause, which cause shall, at his request, be given him, and he shall be given a full and fair opportunity to explain or disprove the same, by himself or a committee of said company's employees, to be selected by said discharged employee.

4. Questions of schedules and of wages shall not be submitted to arbitration. The company shall have the ultimate right to hire and discharge men, contracting with them individually, and not collectively. It shall take back into its employment such of its former employees as its business demands, aggregating at the present time 80 per cent of such employees, and as other vacancies occur shall give preference to such former employees, excepting always those who have committed unlawful acts against the company, its property, or its employees, during the present strike; but the rehiring of all men shall be upon the express condition that their services with the company's present employees must be loyal, and the latter must not be subjected to annoyance or abuse by them, and any violation of this condition shall be deemed cause for discharge.

5. The services of the employees shall be distributed as equitably as possible under existing conditions. The company shall at once, upon the return of its former employees to its service, give 80 per cent of the runs to the former employees and 20 per cent of the runs to its present employees; the remainder of its former and present employees to be placed on the extra list in the same proportion. The method of apportioning these runs between former and present employees shall be as follows:

The first four runs on the time-table of each line shall go to the former employees, the fifth run to the present employees; the next four runs to the former employees, and the tenth run to the present employees, and so on through the time-table, with the day runs, late runs and extra list.

Temporarily this adjustment may work some inequalities to some men, but the same will be adjusted as equitably and promptly as possible on these lines.

These propositions the committee deem equitable to both present and former employees and to the company, and recommend the same for your acceptance. Unless acted upon and accepted at once, the committee believes its service will be of no further avail. The committee is fully aware that the public services cannot longer await the adjustment of this difficulty. Some means will have to be adopted at once to provide for the public needs on this company's lines.

The above proposition was agreed to and signed, as follows:

The Cleveland Electric Railway Company, by H. A. Everett.

L. B. Whitney, R. S. Thompson, Everett Todd, Thomas McHugh, George S. Gilmore, A. N. Miller, strikers' committee.

It will thus be seen that the company has virtually won the strike, its refusal to make its system a union road being consistent and absolute. The later reports from Cleveland are that the strikers are not observing that clause in the contract which provides that new men taken on during the strike must not be subjected to annoyance or abuse by the old men. There have been a number of riots, due to the presence of new men on the cars, and they are at the present time being treated with great harshness by the old men.

Tapping an Oil Pipe Under Pressure

BY J. F. HOBART

An oil cup which was piped into the engine supply pipe several feet above the engine, recently became detached by the thread stripping out where the small pipe was screwed into the larger one. This allowed the steam to escape into the engine room rather too freely for comfort, until a pine plug was driven into the hole where the pipe came out. Soon the engine began to groan (in the cylinder) from lack of oil, and it became absolutely necessary to get the $\frac{3}{8}$-in. pipe connection in again.

The thread had come so completely out that the pipe could not be screwed back in again, and it seemed impossible to tap the thread in that hole, with 120 lbs. steam pressure in the pipe. The engine could not be shut down, for it was driving cars and working up to the limit with no relay, pending the putting in of a duplicate engine beside it.

The job was finally done in this manner: A tap was procured of the right size to fit one size larger pipe, and a reamer was put into a common brace (bit stock), the same as used by carpenters. A piece of heavy sheet packing—it was about ¼-in. thick—was found in the cupboard. The packing was about 3 ft. square. A hole just large enough to squeeze the shank of the reamer through was made in the middle of the sheet of packing, the reamer put through and the brace put on.

Then the plug was taken out of the pipe and the engineer stood right up to that hissing steam pipe—stood on the engine cylinder—and reamed out the hole in the steam pipe until the tap would enter. Then the reamer was removed and the tap put in the brace, and the sheet of packing used as before. It took but a very few minutes after that to tap the hole and start in the bit of pipe with a globe valve on it. After the pipe was in place the job was practically finished as far as the "kink" was concerned, but I have seen the same kind of a shield rigged up for use when a gage glass blew out and there was no way of shutting the valves without getting scalded. The packing did it all right then, too.

Employment Contract in Milwaukee

The employment contract used by the Milwaukee Electric Railway & Light Company in engaging its employees contains the following clauses:

I agree to submit to a medical examination by the company's doctor, and to pay for the same a fee of $1.

I agree to work on trial, under instruction, and without pay five days in said company's shops, and at least ten days on such of its cars as I may be assigned to.

I understand that no compensation is paid to trainmen for time spent by them while engaged "on watch" (which means waiting at any designated point for an opportunity to work), but that wages are allowed only for service rendered while actually employed on said company's cars, and are computed at following rates:

—— cents per hour for first six months after being placed on extra list.

—— cents per hour for second six months after being placed on extra list.

—— cents per hour for second year after being placed on extra list.

—— cents per hour for third year after being placed on extra list.

—— cents per hour after three years' service with said company.

These wages are entirely satisfactory to me, and for which, if given employment, I agree to work contentedly and faithfully.

I further agree that if I am discharged, or leave said company's service voluntarily at any time during or after the trial period above referred to, I shall have no claim against said company for services rendered or expenses incurred by me during said trial period or while performing duty "on watch," as above explained.

When placed upon the extra list I agree to deposit with the company, without interest, the sum of $25 as a surety fund for the faithful performance of my duty.

I agree within thirty days after being placed on the extra list to provide myself, at my own expense, with a standard uniform, in accordance with the rules and regulations of the company.

So long as I remain in its service I agree to study carefully and comply faithfully with all rules, regulations and orders of the company.

In witness whereof I have hereunto set my hand and seal at Milwaukee, Wis., this —————— day of ——————, 18—.

Electrical Exposition in Chicago

The National Exposition of Electrical Arts Company has been organized in Chicago and incorporated, with a capital of $50,000, in the State of Illinois, for promoting an exposition to be held at Tattersalls, Sept. 25 to Oct. 9. Coming as it does at the time of the fall festivals in Chicago, the exposition gives promise of meeting with very great success. The autumn carnival, to be held in connection with the laying of the corner stone of the new post-office, will be in progress on the date set for the opening of the exposition, and, as there will be thousands of visitors in Chicago, the exposition will undoubtedly be one of the chief attractions. The officers of the exposition company are N. J. Heimbach, president; W. E. Burnham, treasurer, and T. Carrabine, secretary, names well known among Chicago business men.

It is the intention to make this a general electrical exhibition. Manufacturers of electrical apparatus from all over the country are already signifying their willingness to co-operate, and the exposition will be one of the most complete ever held in Chicago.

The American Street Railway Association will have its exhibition in the same building, beginning a few days after the first one closes. This increases the interest of the latter to street railway men and manufacturers of street railway apparatus. Those who intend making exhibits at the street railway convention can, with very little additional expense, arrange to present their exhibits at the National Exhibition of Electrical Arts. All applications for space should be sent to the Exposition Company in the new Life Building, Chicago. Tattersalls Building will be handsomely decorated and lighted.

Space will be leased to exhibitors at rates varying according to size and location. The Tattersalls building is 148 ft. x 265 ft. There are 149 exhibition spaces, ranging from 100 sq. ft. to 400 sq. ft. In case of very extensive exhibits two or more sections may be combined. The aisles are from 9 ft. to 12 ft. wide, and plenty of open space is left at the entrance of the building.

Among the concerns that have already signified a determination to take part in the show are the Chicago Edison Company, Chicago Telephone Company, Postal Telegraph Cable Company, the Allen-Hussey Company, Advance Specialty Company, and Eureka Telephone Company. It is probable that gold medals will be awarded for excellence of exhibits.

Recent Sales of Electrical Supplies

Elmer P. Morris, of New York City, reports that during the past month the demand for electric railway supplies has been unusually heavy, and orders have came in from all parts of the world. He has sent poles to Brazil, Cuba, Syracuse, N. Y.; Asbury Park, N. J.; Phœnixville, Pa.; Brooklyn, and Westchester County, New York, and other supplies to Africa, South America, Cuba, Trinidad, etc. The sales of wire have been particularly large.

Mr. Morris has recently appointed two new agents; one the Miller Electrical Maintenance Company, at Pittsburgh, and the other, Henry L. Prather, New England Building, Cleveland, Ohio.

Additions for Brooklyn

The Westinghouse Electric & Manufacturing Company is executing an important contract for increasing the electric plant of the Coney Island & Brooklyn Railroad Company. Last year one power station was equipped with two 500-h.p. Westinghouse compound engines, direct connected to two Westinghouse generators of 500 h.p. each, to deliver current at 550 volts for the railroad. A duplicate outfit of 1000 h.p. is now being provided for the Smith and Knight Streets power station. In addition there will be installed a 500-kw. Westinghouse generator, with a series wound booster, direct connected to a steam engine, to do railroad work. A two-paneled switchboard is included in the outfit.

Major-General Leonard Wood, Military Governor of the Province of Santiago, has received an offer of the presidency of the Washington (D. C.) Traction & Electric Company, but he has not yet signified his decision in the matter, and will sail for Cuba on July 3 or 4, to continue his work in Santiago, at least for the present. General Wood's great organizing and executive ability, his long residence in Washington, and his high reputation in every way would seem to make him an almost ideal man for this position, but it is doubtful if he can be induced to give up his army career.

Convention of the Ohio Street Railway Association

The annual convention of the Ohio Street Railway Association was held at Springfield, Ohio, June 14. There were twenty-four members and visitors in attendance. The morning was spent in visiting the power house of the local company and in taking an inspection trip over several of its lines. After dinner at the Arcade Hotel, the convention convened at the Lagonda Club.

There were no papers read, but a general and informal discussion was indulged in, the chief subjects being how best to further the interests of the association and the procuring of new members.

New members were added to the association as follows: Wheeling Railway Company, Wheeling, W. Va.; Mansfield Electric Railway Company, Mansfield, Ohio; Canton & Massillon Electric Railway Company, Canton, Ohio; Zanesville Electric Railway Company, Zanesville, Ohio.

Cincinnati was chosen as the next meeting place of the association, the meeting to be held on the second Wednesday of June, 1900. Officers for the ensuing year were chosen, as follows: S. L. Nelson, president, Springfield, Ohio; J. F. Flood, vice-president, Steubenville, Ohio; Charles Currie, secretary and treasurer, Lima Ohio; executive committee—A. A. Anderson, Youngstown, Ohio; W. A. Lynch, Canton, Ohio; T. H. McLean, Toledo, Ohio.

After supper the members and visitors repaired in a body to the Elks Street Fair, which was in progress in the city, and where a most enjoyable evening was spent. The members and visitors in attendance were as follows: B. Walker Peterson, vice-president, Wheeling Railway Company, Wheeling, W. Va.; Charles Currie, secretary and treasurer, Ohio Streeet Railway Association, Lima, Ohio; E. J. Wehrly, general manager, Arbuckle-Ryan Company, Toledo, Ohio; H. C. Fogle, general manager, Canton & Massillon Electric Railway Company, Canton, Ohio; A. L. Wilkinson, Ohio Brass Company, Mansfield, Ohio; Charles Hodge, Westinghouse Electric & Manufacturing Company, Columbus, Ohio; John Harris, superintendent, Cincinnati Street Railway Company, Cincinnati, Ohio; G. A. Schroeder, Multiplex Reflector Company, Cleveland, Ohio; F. H. Strieby, General Electric Company, Cincinnati, Ohio; C. S. Nolloth, Standard Electric Company, Cincinnati, Ohio; F. E. Ginn, superintendent, Lancaster Traction Company, Lancaster, Ohio; C. E. Harrison, Hildreth Varnish Company, Steubenville, Ohio; O. C. Evans, Lorain Steel Company, Cincinnati, Ohio; William H. Sinks, Varney & McOuat, Indianapolis, Ind.; C. S. McMahon, Street Railway Journal, Chicago, Ill.; H. J. Kenfield, Street Railway Review, Chicago, Ill.; Arthur E. Jones, National Lead Company, Cincinnati, Ohio; G. R. Scrugham, Creaghead Engineering Company, Cincinnati, Ohio; Lou. Williams, superintendent, Springfield Railway Company, Springfield, Ohio; H. A. Dorner, Dorner Truck & Manufacturing Company, Cleveland, Ohio; W. R. Morrison, assistant general manager, Bay City Electric Railway Company, Bay City, Mich.; Reid Carpenter, Mansfield, Ohio; C. H. King, Ohio Brass Company, Mansfield, Ohio; P. Leidenger, Dayton Manufacturing Company, Dayton, Ohio.

The entertainment provided by S. L. Nelson, of the local company, was most hospitable, and the Ohio Street Railway convention at Springfield will be long remembered by all present.

The Ohio Brass Company exhibited its emergency hose bridge, and a test of it was made on the local line, the exhibit being attended by all present in a body. A number of cars were run over the bridge, both rapidly and slowly, and with absolutely no inconvenience; in fact, it scarcely seemed an obstruction. This bridge is now in use in Chicago, Dayton, Cleveland, Toledo, Nashville and other cities. The company states that it is meeting with universal success.

Varney & McOuat, of Indianapolis, through William H. Sinks, exhibited armature coils, of which this company is now making a specialty. The company is doing a large repair business for railways throughout the Central States. The company's excellent work, together with its central location and excellent shipping facilities, is building up a large business.

The Multiplex Reflector Company, of Cleveland, Ohio; was represented by George A. Schroeder, who exhibited one of the company's new multiplex reflector lamps. These lamps are no more expensive than others in use, and throw a most powerful light, owing to the peculiar construction of the reflector.

Virginia Street Railway Association

The latest State street railway association to be organized is that of Virginia. The association of that State includes both electric railway and lighting interests, and held its first annual meeting at the Hotel Jefferson, Richmond, May 16. Representatives were present from electric railways in Stanton, Norfolk, Richmond and Lynchburgh. The papers read were on "Track Bonding," by R. D. Apperson; "How to Increase Revenue of Electric Light Stations;" "Park Amusements," and "The Use of the Wattmeter on Electric Cars to Check the Unnecessary Use of Current." Mr. Apperson, in his paper, stated that he used the plastic bond on his railway, and referred to it in the highest terms.

The Washington Consolidation

The bankers who are financing the Washington consolidation have just issued a prospectus of the Washington Traction & Electric Company, and offer $12,000,000 out of an authorized issue of $20,000,000 of first mortgage, collateral trust 4½ per cent, fifty-year gold bonds. This company controls eight street railway companies, with 116 miles of track, and the only two electric light companies in the city, with 72 miles of subway, about 400 miles of duct, and many miles of overhead wires. The Capital Traction Company is the only railway in the city not in the consolidation. Of the $20,000,000 bond issue, $6,558,000 is reserved to retire outstanding bonds of constituent companies, $1,442,000 is held for future uses of the company, and the remaining $12,000,000 is now issued as stated. An estimated statement of earnings for the year ending July 1, 1900, issued by Messrs. Stevens, Crosby and Lieb, is as follows:

Gross earnings of railway properties	$1,750,000
Gross earnings of lighting properties	550,000
Total	$2,300,000
Operating expenses	1,150,000
Net income	$1,150,000
Total fixed charges	887,480
Surplus over charges	$262,520

H. H. Vreeland and F. S. Pearson, in their report to the United States Mortgage & Trust Company, estimate that the gross revenue of these properties will be $1,850,000 per annum, and that the operating expenses should not exceed 50 per cent at first, and 40 per cent eventually, of the gross receipts. They estimate also that within three years the electric lighting properties should earn at least $1,000,000, and the percentage cost of operation should not exceed that of the railways. Within three years' time the combined revenue from the entire consolidated properties should not, they say, be less than $3,000,000.

The different lines comprising the Washington Traction & Electric Company's system are being put in first-class shape, and a number of extensions are under way. The contractors for the work are J. G. White & Co., of New York, who are now building about 35 miles of new track and 45 miles of overhead work; the track work, including the laying of both girders and T rails, and comprising the reconstruction of the present track and overhead work of the Georgetown & Tennalytown Railroad and the extension of this line to Rockville; the reconstruction of the Brightwood Railway, including branches to the Soldiers' Home and Tacoma Park; the reconstruction of the Washington, Woodside & Forest Glen Railroad, including relining, surfacing and ballasting the present tracks and rebuilding overhead work; rebuilding the overhead line of the Glen Echo Railway, and rebuilding the overhead line of the Great Falls Road. The construction is all first-class in every way, a greater part of the T rail being rock ballasted. The overhead construction will all be double trolley, positive and negative. The size of the trolley wire will be 00.

The New York & Long Island Tunnel

The Long Island & New York Terminal Railroad Company was incorporated June 17, with a capital stock of $7,500,000, for the purpose of constructing a tunnel from the present terminus of the Long Island Railroad on Atlantic Avenue, Brooklyn, to the Manhattan Island terminus at the corner of Cortlandt and Church streets. The directors of the company represent many important financial interests, and are trustees of enormous capital, so that there is no doubt that the work will be entered upon immediately and pushed through as rapidly as possible. President Baldwin, of the Long Island Railroad, states that a force of men has been at work for more than a year making test borings in the streets of Manhattan Island and under the East River, and they are now perfectly familiar with the route to be followed, the materials to be encountered and the nature of the work to be done. The Legislature having at its last session granted necessary permission for the work to proceed, the next step will be to obtain franchises from the municipal assembly. There will be two tunnels, or parallel tubes, placed at a depth of 80 to 132 ft., and the lowest point below the surface will be reached at the Brooklyn City Hall.

LEGAL NOTES AND COMMENTS

EDITED BY J. ASPINWALL HODGE JR., OF THE NEW YORK BAR

The Right of a Street Railway to Carry Freight

In a brief, recently filed by eminent counsel, in an action where the right of a street railway to carry freight or express, it is stated that "from 1834, when John Stephenson invented the first street railway car, to within a period of one year no street railway company ever claimed or asserted the right to operate cars exclusively for the transportation of property." This, we believe, is a much broader statement than the facts justify. It would be interesting to learn of the earliest date when such a car was operated by a street railway in this country; but the vital question is not whether, or when, the right was claimed, but whether it *exists* under present statutes of the various States.

The question is being litigated in the action referred to *(DeGrauw vs. Long Island Electric Railway Co. et al.)*, and is pending before the appellate division of the Second Department of the Supreme Court of New York.

The plaintiff asked for an injunction restraining the defendant from operating a car devoted, exclusively, under a contract with the National Express Company, to the carriage of express packages between two depots of the express company in the Borough of Brooklyn. A demurrer of complaint was sustained in the court below, on the ground that the New York act granting to street railways the right to carry "passengers and property" included the right to run such a car, and the plaintiff has appealed from that decision.

The plaintiff's appellant contention is briefly: that no such right can be implied. If it exists it must be founded upon some express provision of law; that construing the words "passengers and property" in connection with the subject matter of a street railway act, applying the maxim "*noscuntur a sociis*," the words mean "passengers and passengers with property," and do not mean "passengers and freight;" that the legitimate uses of a street do not include the transfer of freight and express, and certainly do not include the transfer of the same from fixed places under contract with a particular individual or corporation, the public generally not benefiting, directly, thereby. In support of these propositions many *dicta* from decisions were cited, wherein it was stated that "street railways transport passengers only," while "commercial railroads carry both passengers and freight;" the first, stop at short intervals, on the highway to take passengers, off and on, and the latter receive and discharge both passengers and freight at regular depots, further apart. *East End St. R. R. Co. vs. Doyle, 9 L. R. A. (Tenn.), 100; Louisville, etc., R. R. vs. City R. R., 2 Duval (Ky.), 178; Funk vs. St. Paul R. R., 29 L. R. A. (Minn.), 208; Nichols vs. Ann Arbor R. R., 16 L. R. A. (Mich.), 374.)*

Among the text-book writers Messrs. Booth, Elliott and Rorer were cited.

On the behalf of the defendant-respondent it was urged with much force that the words "passengers and property" were precisely the same words which are used in the general railroad act of New York, and in fact to-day are used in a section of the railroad law which, by express provision, applies both to steam and street railways. And further, that prior to the Constitution of 1875, special acts were passed by the Legislature, granting to particular street railways various powers, and in some cases expressly prohibiting the carrying of freight; in other cases the special acts gave them the right to carry passengers without any reference to property at all. It was contended in the light of these statutes that the words "passengers and property" used in the general act must mean passengers and freight.

The weight of authority would seem to support the defendant's contention where these words are in the statute.

In considering the decisions in any particular State it is, of course, quite necessary to examine, carefully, the charter or the general act under which the street railway is formed, to determine what authority is given to it. In that connection it should be remembered, that the franchise to construct and operate a street railway is one that must be conferred by the State, and that its power is sovereign over the streets.

A serious problem is presented in New York, if the contention of the Long Island Electric Railway Company is sustained, since, under the decision of the case of the Broadway surface road *(People vs. O'Brien, 111 N. Y., 1)*, it would appear that this right, if now held by the street railroads of New York, can be exercised even against the will of the Legislature, on the ground that to deprive them of the right they now hold, would be taking away a property right, protected by the Constitution of the United States.

In such city streets as are now crowded with passenger cars the running of numerous freight or express cars might work to the public inconvenience, rather than to the public convenience. While, in the great majority of cases, it is obvious that the carrying of freight and express upon rails would work a great public benefit, whether within city limits or between towns and cities.

The problem is one of the present and future, and the courts may be trusted to develop the law in accordance with the needs of the public and the improvements of the age, according to the now well-established doctrine which is ably expressed in the Diamond Match Company case *(Diamond Match Company vs. Roeber, 106 N. Y., 473, 481)*.

CHARTERS, ORDINANCES, FRANCHISES, ETC.

IOWA.—Duty to Refloor Bridge—Ordinance.

Under an ordinance authorizing a corporation to operate a street railway over certain streets, avenues and bridges, and requiring it to keep in repair that portion of such paved streets and highways which is included between its tracks and one foot on either side, and to pave such portion of any street or avenue when ordered by the council, the company is not bound to refloor with oak plank any portion of a bridge over which its tracks pass.—(City of Cedar Rapids vs. Cedar Rapids & M. C. Ry. Co., 79 N. W. Rep., 125.)

MASSACHUSETTS.—Parol Evidence—Illegal Sale.

1. Parol evidence to contradict the terms of a note is inadmissible.

2. Plaintiff was constructing a street railroad for the I. Company, but, before completion, was notified that it would not be accepted. Some three miles of the road had been finished, except the overhead work. Thereupon plaintiff acquiesced in such refusal, and sold "all the material and other property now being on the line of the street railway" to the A. Company, and agreed to take their notes in payment therefor. The purchasing company, by resolution of its directors, voted to buy "all the material and other property owned" by the plaintiff. At the same time plaintiff agreed to credit all sums received from the A. Company in payment of its claim against the I. Company. A short time thereafter the A. Company was operating the line. Held, that as soon as the rails were annexed to the soil by the plaintiff they became the property of the I. Company, within the meaning of Pub. St., chap. 113, sec. 56, forbidding a street railway company to sell or lease its road; that the refusal to accept them did not change this fact; and that, if the whole transaction was a scheme whereby the I. Company attempted to sell the road being constructed by plaintiff to the A. Company, it was illegal, and the notes given in consideration thereof were void.

3. For the purpose of showing the real nature of the transaction, oral evidence of what was said and done at the meetings of the directors of the companies at the time the matter was under

* Communications relating to this department may be addressed to the Editor, Johnston Building, 30 Broad Street, New York.

consideration by them is admissible.—(Clemons Elec. Mfg. Co. vs. Walton, 53 N. E. Rep., 820.)

MISSOURI.—Operating Over Other Lines—Injunction—Damages—Jurisdiction—Appeal—Reversible Error.

1. Where, pursuant to St. Louis city charter, art. 10, sec. 6, providing that any street railway company may run its cars over any other company's lines, on payment of compensation, under such regulations as may be prescribed by ordinance, ordinances were passed authorizing one company to operate its cars over the lines of another, and providing the manner of adjusting compensation, and such compensation had been fixed and accepted by the latter company, it is not entitled to an injunction to restrain the former from operating cars which interfered with the running of its cars, and from using certain modes of connection, where the connections were made according to the latter's plans, and the inconveniences suffered were the natural result of the legitimate use of the connections.

2. The court had jurisdiction of the subject-matter of the action, since, under the petition, complainant might introduce evidence showing that defendant had connected its tracks in a manner not authorized, and was running cars not contemplated by the award, to plaintiff's continuous damage.

3. Error in rendering judgment in plaintiff's favor, of which he cannot complain, is not reversible, where he alone appeals.—(People's Ry. Co. vs. Grand Ave. Ry. Co., 50 S. W. Rep., 829.)

NEW YORK.—Receivers—Claims.

A debt incurred for supplies furnished an elevated railway company prior to the appointment of a temporary receiver, in an action to foreclose a mortgage on its property, under Code Civ. Proc., sec. 1788, is not a preferred claim, and the receiver will not be ordered to pay it.—(Mercantile Trust Co. vs. Kings County El. Ry Co. et al.—in re Lovell et al.—57 N. Y. Suppl., 892.)

NEW YORK.—Change of Motive Power—Inference.

1. A horse railroad consists of two tracks laid on opposite sides of the two tracks of an underground trolley system occupying the middle of a street 50 ft. wide between the curbs, and there is 32 ft. between the outside rails of each track of the horse railroad. A change of its motive power to the underground trolley system contemplates that the cars will project over the rails so that there will be less than 12 ft. of clear space between them and the curb, but the rails are to be laid flush with the surface and the cars are to be run intermittently. Held, that it could not necessarily be inferred that the change would permanently obstruct it, and result in an exclusive appropriation of a portion of it to other than customary street uses, and that it would depend on the speed and frequency with which cars were run.

Same—Right to Change at Will.

2. Laws 1873, chap. 825, granting the right to construct, operate and maintain a street railroad by steam, animal or mechanical power over certain streets and avenues in New York city, including what is now Amsterdam Avenue, does not empower owners of the franchise to change at will the motive power of a constructed road, irrespective of the consent of the railroad commissioners or property owners.

Same—Consent of Propertyowners.

3. Laws 1890, chap. 565, sec. 100, providing that a street surface railroad may change its motive power on the consent of "the owners of one-half of the property bounded on that portion of the railroad with respect to which a change of motive power is proposed," contemplates that a majority of those owning property, measured by its extent in lineal feet along the route as to which a change of power is proposed, shall consent.—(St. Michael's Protestant Episcopal Church in City of New York vs. Forty-Second St., M. & St. N. Ave. Ry. Co; Society for Relief of Destitute Blind of City of New York and Its Vicinity vs. Same, 57 N. Y. Suppl., 881.)

NEW YORK.—Payment of Judgment—Right to Recover Back—Mistake.

After the denial by the Appellate Division of an application for leave to appeal to the Court of Appeals from an affirmance of a judgment, and during the pendency of an application to the Court of Appeals for leave to so appeal, made without the procurement of a stay of execution, the judgment debtor, erroneously believing that his application to the Court of Appeals had been rejected, paid the judgment on the creditor's threat to issue execution. Held, that, on being granted leave to appeal, the judgment debtor could not recover back the amount paid under a mistake, since the payment, made while the right to issue execution on the judgment existed, was voluntary.—(Third Ave. R. Co. vs. Klinker et al., 58 N. Y. Suppl., 136.)

OHIO.—Ejectment—When It Lies—Recovery of Possession of Streets by City.

1. Ejectment will lie by a city to recover possession of streets in which the public has an easement.

Courts—Following Prior Decisions.

2. Defendants, claiming as licensees of a city in a suit by adverse claimants, set up and successfully maintained the right of the city to certain land under a dedication for street purposes. Held, that in a subsequent action by the city against the defendants, the evidence being practically the same, the former decision as to the validity of the dedication as claimed by the city would be followed, on the principle of stare decisis, though the city was not a party to the adjudication.

Municipal Corporations—Abandonment of Street—Intention.

3. Where a city had granted, or attempted and assumed to grant, the right to defendants to use ground it claimed as a street, its acquiescence in such use for any length of time will not operate as an abandonment of its claim to the property.

Estoppel—Acts in Pais—Construction of Party's Conduct.

4. The conduct of a party, sought to be made the basis of an estoppel against him, must be viewed in the light of the understanding he then had of his rights, and not in the light of such rights as they may be thereafter determined.

Same—Acts of City.

5. In 1849 the city of Cleveland entered into a contract with certain railroads, by which it granted them the right to use a portion of a tract of land claimed as a street. Not long afterwards, in a suit against the railroads by an adverse claimant, the defendants alleged their interest in the land to be that of licensees of the city, and successfully defended on the city's title under a prior dedication. Held, that the city, by permitting the railroads to remain in undisturbed, or even exclusive, possession of the ground for forty-five years, and to expend large sums in the construction of improvements thereon without objection, was not estopped, as against them, to claim any rights in the property consistent with the contract, according to the construction and meaning given it by the defendants in their pleading in the former suit, where they had never given notice of any other or different claim.

Limitation of Actions—Ejectment—Nature of Defendants' Possession.

6. Nor can the defendants in such case successfully plead limitation against an action by the city, whatever may be the true construction of the contract under which they took possession, or the nature of their rights otherwise acquired, as by their own admission, in a sworn pleading, their holding was not adverse to the city, and it had the right to rely on such admission until notified that they claimed under a different tenure.

Same—Admissions in Pleadings.

7. A formal allegation in a petition in ejectment that, on the date it is filed, defendants unlawfully keep the plaintiff out of possession of the property, is not an admission that defendants' possession is adverse which will support a plea of limitation, on proof that they have held in the same right for more than the statutory length of time.

Rights to Public Grounds—Construction of Contract with City.

8. Under the constitution of Ohio of 1802, the only restriction upon the exercise of the power of eminent domain by the Legislature was the provision that money compensation should be made for private property when taken for public use, and by the railroad act of 1848 (46 Ohio Laws, p. 40) railroad companies were given power to construct and maintain railroads between the points named in their respective charters, and to appropriate streets or other public grounds to their use when necessary, either by agreement with the public authorities, or, such agreement failing, by a decree of a court. Held, that a contract made in 1849, while such act was in force, between a city and a railroad company, by which the city granted, "as fully and absolutely" as it had the power or legal authority to do, the right to the "full and perpetual use and occupation" of a portion of a street required by the railroad company for terminal purposes, did not reserve to the city any rights in, or control over, the property described, but that the railroad company took from the State under the statute, and not from the city, an easement of a perpetual and exclusive use.—(City of Cleveland vs. Cleveland, C., C. & St. L. Ry. Co. et al., 93 Fed Rep., 113.)

PENNSYLVANIA.—Contracts for Use of Tracks—Construction—Estoppel—Parties.

1. The S. Co. has no such substantial interest in the subject of the right of the T. Co. to use the tracks of the S. Co. under an agreement between the P. Co. and the A. Co. as will authorize the entertaining of its bill to enjoin the use thereof, where all the stock of the S. Co., except five shares, which are unrepresented, and the owners of which have made no objection, is owned by the P. Co., which has for years had possession of and run the road of the S. Co.

2. The P. Co. is estopped from contesting the validity of an agreement for use of its tracks by the A. Co. on the ground that it was not authorized by the directors, or reported to and approved by a meeting of the stockholders, where the officers of the P. Co. were the movers for the agreement, and it was sanctioned by its

attorneys, and approved, before it was made, by a majority of its stockholders, and was reported by its president to the next annual stockholders' meeting, when no objection was made to it, and it has been carried into effect fully and completely; the tracks being repaired, payments made, and the road operated thereunder for several years.

3. The T. Co., which owns all the stock of the A. Co., and has a lease for 999 years of all its franchises, property and rights of every kind, is an "assign" of it, within a contract giving certain rights to it and its assigns.

4. A contract which gives the A. Co. and its assigns the right to run its cars over the tracks of the P. Co. for a certain consideration, though not requiring a greater consideration in case of an increase in the number of cars, does not allow an assign of it, which owns other lines, to run its cars, and in addition those of the other lines owned by the assign, over such tracks for such consideration.—(South Side Pass. Ry. Co. vs. Second Ave. Pass. Ry. Co. et al.; Pittsburg & B. Traction Co. vs. South Side Pass. Ry. Co. et al., 43 Atl. Rep., 346.)

WASHINGTON.—Taxation—Validity of Assessment—Ownership of Property.

1. The power house and other buildings of an electric street railroad company were situated on a tract of land, a part of which was owned by the company and a part held under a lease for twenty-five years, which bound the company to pay the taxes thereon. Held, that the company might properly be regarded as the owner of the entire property for the purposes of taxation, and its assessment as an entirety was valid.

Same—Improvements on Real Estate.

2. Where a street railroad company may properly be regarded as the owner, for the purposes of taxation, of leased land upon which its power house and plant are in part situated, such buildings are taxable, under the statutes of the State of Washington, as a part of the real estate.

Same—Railroad Right of Way—Actual Use for Other Purposes.

3. Under the statute of Washington (1 Hill's Ann. Code, sec. 1046), providing that all lands occupied and claimed exclusively as right of way for railroads must be assessed as a whole, and as real estate, at a certain sum per mile, a part of the designated right of way of a railroad, but which is in the actual use and occupation of a street railroad company for purposes of its power plant, under a lease for twenty-five years, cannot properly be taxed as a part of the right of way of the railroad company.—(N. Y. Guaranty & Indemnity Co. et al. vs. Tacoma Ry. & Motor Co. et al., 93 Fed. Rep., 51.)

LIABILITY FOR NEGLIGENCE.

ALABAMA.—Collision with Buggy—Willful Injury.

Where a horse and top buggy, inclosed by curtains, moving in the same direction as, and about 100 ft. ahead of, a street car, running five or six miles an hour, turned to cross the tracks, and the motorman, though he saw the buggy turn, failed to slacken speed or give warning, and the car struck the buggy, his conduct amounted to a willful injury.—(Birmingham Ry. & Elec. Co. vs. Smith, 25 So. Rep., 768.)

CALIFORNIA.—Negligence—Sprinkling Carts—Trial—Questions for Jury—Compromise and Settlement—Evidence—Ratification.

1. Plaintiff was rightfully driving a street sprinkler on a street car track. According to his custom, on turning into the street on which the tracks were, he followed rapidly behind a passing car, sprinkling the street as he went, and turned around several times to see that no accident might happen. A car coming behind plaintiff sounded the only warning bell 700 ft. away, and then came on with accelerated speed; not attempting to slack the car until within two or three car lengths of the cart, and even then not using the most effective appliance for stopping the car. The cart and its load weighed five tons, and made considerable noise when sprinkling. Held, that the street car company was negligent, so as to be liable for the injuries to plaintiff.

2. A person severely injured by an accident compromised the claim next day, and made his mark as a signature to the receipt. He testified that his mind was a blank as to the occurrences from the time of the injury until several days after the alleged settlement, when he was taken to a sanitarium. Two witnesses testified that he spoke of the settlement after coming to the sanitarium, and there was nothing to show that at that time any one had informed him of the settlement. Held, that the question whether he had knowingly settled the claim was for the jury.

3. Evidence of a person who had been injured, that he knew nothing of what occurred the next day, when he made an alleged settlement of his claim, is equivalent to a statement that he was "entirely without understanding" at such time.

4. The retention of money paid in settlement of a claim for personal injuries is not a ratification of the settlement, where retained without knowledge of how it was obtained.

5. Where the jury was instructed that they might deduct from the amount of damages for personal injuries any money given to plaintiff by defendant by way of an alleged settlement, defendant cannot complain that it was injured by such payment.—(Los Angeles City Water Co. et al. vs. Superior Court of Los Angeles County; City of Los Angeles vs. Los Angeles City Water Co. et al., 57 Pac. Rep., 216.)

CALIFORNIA.—Injuries to Passengers—Evidence—Pleading—Damages.

1. Where a passenger was thrown from a street car while rounding a curve and injured, his testimony that the car was going at an unusually rapid rate of speed is sufficient to sustain a verdict, where other passengers were thrown at the same time.

2. Under an allegation that the accident was caused by the high rate of speed he may prove that the fall was occasioned by a sudden jerk, accompanied by the high rate of speed.

3. Evidence that uterine trouble was caused by an accident due to defendant's negligence is admissible under a general averment of bodily injury and resulting damage.—(Samuels et ux. vs. California St. Cable Ry. Co., 56 Pac. Rep., 1115.)

GEORGIA.—New Trial—Instructions—Arguments of Counsel—Injury to Passenger—Evidence—Appeal—Review—Pleading—Amendment.

1. That the contentions of one party were not as specifically set forth in the charge of the court as were those of the other was not cause for a new trial, when the charge as a whole fully, fairly and correctly covered the law applicable to every issue in the case.

2. There was no error in refusing to give a request in charge which implied that counsel for the adverse party had made an improper appeal to the jury, when, as shown by the certificate of the trial judge, no such appeal was made.

3. Refusal to give requests in charge is not error, when, so far as legal, they are fully covered by the general charge.

4. Where counsel for the defendant objected to certain language used by plaintiff's counsel in his argument to the jury, upon the ground that it was an appeal "to make a verdict based on matters not in the plaintiff's declaration and suit," and thereupon the presiding judge stated to the jury that "the position of the defendant's counsel was the law, and the jury should take it as such," and gave further appropriate instructions upon the subject, after verdict a new trial should not be granted the defendant upon the ground that "the court should have given direct and unqualified disapproval of such appeal to the jury, and that the response of the court to the point made by defendant's counsel on that line of argument was not adequate in view of the nature of the appeal made." The defendant's counsel should have requested such instructions as, in his opinion, would have been sufficient to remove any improper impressions made upon the minds of the jurors by the unauthorized appeal of plaintiff's counsel, or moved that the case be withdrawn from the jury and a mistrial declared.

5. The cries or exclamations of bystanders upon seeing an accident about to occur may be proven to explain the state of mind and conduct of a person hearing them, and who is injured in the accident.

6. This court cannot undertake to determine whether or not error was committed by the trial judge in refusing to permit counsel to ask a witness and have him answer a given question, when it does not appear what the answer thereto would have been had it been allowed. (a) A witness who is not an expert as to the subject upon which he is questioned is incompetent to give an opinion thereon, without stating the facts on which his opinion is based.

7. Though in defense to the plaintiff's contention that the person for whose benefit the suit was proceeding was injured by reason of the negligent running of the defendant's cars, the latter introduced evidence tending to show that the injury could have been caused or aggravated by excessive sexual intercourse, there was, under all the facts and circumstances, no error in rejecting other evidence offered to show that a given person had caressed, hugged and kissed such injured party.

8. Where the defendant offered to prove by a witness that he had taken liberties with the woman for whose benefit the suit was proceeding, and had become intimate or familiar with her, and by another witness the circumstances under which he had seen her and a certain man in the woods, and the intimacy existing between them, this court cannot determine whether or not error was committed in the rejection of such evidence by the trial judge, when it does not appear what the acts or circumstances constituting such familiarities or intimacies were.

9. There was no error in rejecting evidence offered to show the state of feeling existing between certain witnesses.

10. There is no merit in a ground of a motion for a new trial which complains that the court erred in allowing a given amendment to the declaration "after the trial had commenced, and when there was no opportunity for medical examination of the plaintiff" as to the additional injury alleged in the amendment; especially where it does not appear that the defendant objected to the amendment for any reason.

11. The evidence for the plaintiff was amply sufficient to authorize the verdict, and in the light of such evidence the verdict was not excessive.—(Atlanta Consol. St. Ry. Co. vs. Bagwell; Bagwell vs. Atlanta Consol. St. Ry. Co., 33 S. E. Rep., 191.)

INDIANA.—Injuries to Person on Track—Proximate Cause—Contributory Negligence—Vehicles—Right of Way.

1. Where the driver of a sprinkling cart saw a street car approaching, but erroneously thought he could cross the track before it reached him, there being no sudden or unexpected peril, his act was the proximate cause of his injury.

2. There can be no recovery for injuries where plaintiff's negligence proximately contributed thereto, unless defendant's negligence was willful.

3. The right of a vehicle to cross a street car track is subject to the superior right of way of the street car company.—(De Lon vs. Kokomo City St. Ry. Co., 53 N. E. Rep., 847.)

KENTUCKY.—Starting of Streeet Car Before Passenger Has Alighted—Evidence.

1. Though a street car has been stopped without a signal, yet where the driver sees a passenger about to leave the car, when he ought to know that such is her purpose, it is negligence on his part to start the car before she has had time to alight.

2. Evidence that it is customary for passengers to leave the car while in motion is not admissible to excuse the act of the driver in starting a car before a passenger has alighted.—(Louisville Ry. Co. vs. Rammacker, 51 S. W. Rep., 175.)

MASSACHUSETTS.—Master and Servant—Injury to Servant—Assumption of Risk.

Plaintiff was ordered by defendant to get on a pile of lumber and throw off a piece of timber, and was injured by the collapse of the pile, which had been defectively built. He had been working near the pile for two days, but there was no evidence that he knew it was defective, or that its defect was apparent. Held, that he did not assume the risk.—(Millard vs. West End St. Ry. Co., 53 N. E. Rep., 900.)

MICHIGAN.—Disorder on Street Car—Failure to Let Passenger Off—Conflicting Evidence.

In an action for injuries through failure to let a woman off a street car after disorderly persons began fighting thereon, evidence of plaintiff that the conductor stood in the front door, and that "he did not say anything to me when I screamed and wanted to be let off—never moved"—and paid no attention to her, and of a witness who saw the car pass, that she saw the conductor standing where plaintiff said he stood while the struggle was in progress (in the middle of the car), contradicts defendant's evidence that the conductor was engaged in attempting to disarm one of the disorderly persons when he responded to her request by calling to the motorman to stop the car, and that he failed on account of an obstruction forcibly placed in his way, so as to take plaintiff's case to the jury.—(Cross vs. Detroit Citzens' St. Ry. Co., 79 N. W. Rep., 11.)

NEW YORK.—Crossing Tracks—Degree of Care—Contributory Negligence.

1. One crossing a street car track at a place other than a crossing is bound to use reasonable care not to obstruct the passage of the car unnecessarily, but he has a right to rely on a delay of the car in its progress to enable him to cross, if it becomes necessary, and contributory negligence cannot be predicated on a mere mistake of judgment on his part.

Same—Jury.

2. Where one driving a heavy wagon at a slow walk attempted to cross a street car track at a place other than a crossing, and got on the track as a car was approaching some 50 ft. away, the question as to whether he used reasonable care not to obstruct the car, and whether the car driver could have avoided a collision by exercise of the same care, was properly submitted to the jury.

Instructions—Error.

3. Refusal of a requested charge covered by the court's charge is not error.

Same.

4. A charge assuming a statement of facts not supported by the evidence is properly refused.—(Lawson vs. Metropolitan St. Ry. Co., 57 N. Y. Suppl., 997.)

NEW YORK.—Evidence—Negligence—Jury.

Plaintiff and one witness testified that plaintiff was thrown to the ground by a street car starting with a jerk after it had stopped to let her off. The conductor and gripman testified that she stepped down facing the opposite way before the car stopped, and that they called to her to wait till the car stopped. Two other witnesses testified that she fell or stepped off before it came to a full stop, and a third that she stepped off just as the car was coming to a standstill. Held, that the question of the company's negligence was for the jury.—(Bennett vs. Third Ave. R. Co., 57 N. Y. Suppl., 994.)

NEW YORK.—Injuries to Pedestrian Under Elevated Road—Evidence.

1. Evidence that an injury was caused by the falling of coals and cinders from a locomotive of an elevated railway company makes a prima facie case of negligence against the company.

Same.

2. Evidence that as a train was passing on an elevated railway, burning coals and cinders were seen to fall, and at the same time plaintiff, who was walking underneath, was struck on the forehead and rendered unconscious, and that the wound showed evidence of burns and contained foreign substances resembling coal, is sufficient to go to the jury on the question whether the injury was caused by coals falling from the engine.—(Kister vs. Manhattan Ry. Co., 58 N. Y. Suppl., 132.)

NEW YORK.—Injuries in Alighting from a Car—Witness—Impeachment—Verdict.

Plaintiff, suing for injuries caused by alighting from a street car, alone testified to the accident. In response to a motion for a bill of particulars, he denied knowing the number of the car, yet on the trial gave it to his lawyer. He testified that two men who picked him up gave him their addresses, yet one had known him before, and testified he did not see the accident, and the other was not produced. Plaintiff testified he was fourteen months in bed as a result of the injury, and had done no work. His physicians testified he was in bed two or three months, and during that time would go out, and visited them at their offices. It was proved plaintiff worked as a night watchman at $7 a week for eleven months between the accident and the trial. He testified he spent $125 for medicines, but could not give the name of a single shop where he spent any part of the money. Held, that the witness was thoroughly impeached, and a verdict based on his testimony alone should be set aside.—(Streicher vs. Third Ave. R. Co., 57 N. Y. Suppl., 716.)

NEW YORK.—Collisions with Vehicles—Contributory Negligence.

1. It is not negligence, as a matter of law, for one driving a wagon at night in the track of a surface railroad to fail to look back to see an approaching car.

Same—Evidence—Province of Jury.

2. In an action for injuries caused by an electric car running into a wagon at night, plaintiff, whose mental ability was somewhat impaired by the injuries, testified that he was driving at a slow walk, that when he heard the bell of the approaching car it was within 25 ft. of him, and that he looked back and turned out of the track, but was struck before he cleared it. A witness testified that the bell was rung when the car was three blocks away, that plaintiff then commenced to turn out of the track, and that the car was coming at a terrible rate of speed. Plaintiff had once before turned out for an approaching car. Held, that the question of plaintiff's negligence was for the jury.—(Bossert vs. Nassau Elec. R. Co., 57 N. Y. Suppl., 896.)

NEW YORK.—Injury to Child in Street.

Refusal to instruct that, if defendant's car was running at a moderate and proper rate of speed, and at the time deceased child left the curb to cross the tracks the car was so close to where deceased was struck that it was impossible for the car, under any circumstances, to be stopped before running over deceased, verdict must be for defendant, is error; the court not having elsewhere instructed as to what would be the duty of the jury, or the rights of the parties, on such a state of facts.—(Weitzman vs. Nassau Elec. R. Co., 57 N. Y. Suppl., 1120.)

NEW YORK.—Collision—Negligence.

Plaintiff stopped his delivery wagon in a street, supposing that he was clear of a street railway track. When within 100 ft. of his destination, he looked behind for an approaching car, but did not discover any. It was dark, but he could see the headlight of a car about 300 ft. Where he stopped the curb was about 6 ft. from the rail. The wagon was about 4 ft. wide, and there was some overhang to the car. Plaintiff, on stopping, stooped to get his packages, when he was struck. Held, that whether he was negligent in failing to look back for a car just at the time he stopped, and to make the necessary observation to see that he was clear of the track, were questions for the jury.—(Black vs. Staten Island Elec. R. Co., 57 N. Y. Suppl., 1112.)

NEW YORK.—Injuries at Crossing—Contributory Negligence.

1. Plaintiff was driving a wagon at an ordinary walk across car, and he was injured. He testified that he looked in both di-

rections before attempting to cross. Held, that a finding that he was free from contributory negligence was justified.

Damages for Personal Injuries—Question for Jury.

2. In an action for personal injuries, where the doctors who examined plaintiff immediately after the accident, and again after his leg had been in a cast for two weeks, refuse to testify that the leg was fractured, merely stating that it might have been, and that there were symptoms so indicating, it should not be left to the jury to determine whether there was a fracture.

Appeal—Reversible Error—Damages.

3. Where the question whether plaintiff in an action for personal injuries suffered a fracture of the leg was submitted to the jury, with no evidence that he did, it is reversible error.—(Weidinger vs. Third Ave. R. Co., 57 N. Y. Suppl., 851.)

PENNSYLVANIA.—Contributory Negligence.

In an action against a street railway company for injuries to plaintiff, one of a gang of workmen repairing a street, the question of plaintiff's contributory negligence is for the jury.—(O'Malley vs. Scranton Traction Co., 43 Atl. Rep., 313.)

NEW YORK.—Injuries on Tracks—Verdict—Weight of Evidence.

Where a number of disinterested witnesses testify for a street railway company that injuries to one driving on the track did not result from the collision of a car with the driver's wagon, but from a subsequent fight between the motorman and driver, precipitated by the latter, a verdict for the latter is against the weight of the evidence.—(Lynch vs. Nassau Elec. R. Co., 58 N. Y. Suppl., 23.)

NEW YORK.—Evidence—Public Records.

In an action against a street railway company for injuries to a horse and wagon through a collision with a car, entries on a blotter of the police department, purporting to be the report of a police officer, respecting the conduct of the motorman at the time of the accident, are not admissible, as such a blotter is not a public record.—(Kerr vs. Metropolitan St. Ry. Co., 57 N. Y. Suppl., 794.)

NEW YORK.—Crossing Accidents—Negligence.

A pedestrian cannot recover for an injury from a street car at a crossing, where there was no evidence that she looked for an approaching car, or as to how far distant the car was when she attempted to cross, or that the accident was due to negligence of the company.—(Balla vs. Metropolitan St. Ry. Co., 57 N. Y. Suppl., 746.)

NEW YORK.—Appeal—Review—Excessive Damages.

A verdict for personal injuries will not be set aside as excessive where the amount is not so large as to show that the jury were actuated by prejudice or corruption.—(Timpone vs. Dry Dock, E. B. & B. R. Co., 57 N. Y. Suppl., 827.)

PENNSYLVANIA.—Trolley Cars—Passengers—Standing on Platform—Negligence.

It is negligence per se for a passenger to remain on the platform of a moving trolley car where there are vacant seats inside the car, though the injury to the passenger was caused by a collision, and he might have been injured had he been inside the car.—(Thane vs. Scranton Traction Co., 43 Atl. Rep., 136.)

OHIO.—Repair of Street Railway—Injury to Traveler—Although one driving a team of horses upon a public street has knowledge that a street railway company has negligently removed the pavement from its tracks and conducting wires, he is not to be charged with negligence if he drives upon the exposed track and wire, not voluntarily, but because his horses are partially beyond his control.—(Farmer vs. Findlay St. Ry. Co., 53 N. E. Rep., 447.)

PENNSYLVANIA.—Actions for Personal Injuries—Limitations—Statutes—Repeal by Implication—Subject—Sufficiency of Title—Vested Rights.

1. The failure of a statute to expressly repeal a former statute on the same subject does not necessarily leave the former statute in full force; it being a question of legislative intent.

2. Act June 24, 1895 (P. L. 236), sec. 1, provides that any right of action which may hereafter come into being by reason of an injury wrongfully done to the person of another shall survive the death of the wrongdoer. Section 2 provides that "every suit hereafter brought to recover damages" for injuries not resulting in death must be brought within two years from the injury. Held, that section 2 is not limited to actions where the wrongdoer dies before suit is brought.

3. Section 1 of the act creates no new right of action, but merely provides for the regulation of a class of rights which existed before.

4. The act embraces but one subject, i. e., actions for injuries wrongfully done to the person.

5. Act June 24, 1895 (P. L.236), entitled "An act providing that the right of action for injury wrongfully done to the person shall survive against the personal representative of the wrongdoer and street car tracks, when the rear end of the wagon was struck by a limiting the time within which suit for such injury must be brought," clearly expresses in its title the second section of the act, which provides that "every suit hereafter brought to recover damages for personal injuries" not resulting in death must be brought within two years from the injury.

6. Act June 24, 1895 (P. L. 236), limiting the time in which to sue for personal injuries, does not interfere with vested rights, in so far as it applies to pending rights of action.—(Rodenbaugh vs. Philadelphia Traction Co., 42 Atl. Rep., 953.)

PENNSYLVANIA.—Relation of Passenger—One who, having received a transfer from one line of a street railway company to its other line, is proceeding from the sidewalk to the car on the latter line, which is standing at the end of the route, when she is struck by a piece of the trolley, which breaks while being changed, as usual at such point, from one end of the car to the other, is entitled to recover as a passenger for her injury, in the absence of a showing that the company has used the highest degree of care.—(Keator vs. Scranton Traction Co., 43 Atl. Rep., 86.)

PENNSYLVANIA.—Injury to Employee—Negligence of Fellow Servant.

1. Where a motorman leaves his car standing on a switch, without setting the brake, and the car, because of such neglect, being on a down grade, moves onto the main track, and collides with a car thereon, injuring the conductor thereof, the injury was caused by the negligence of a fellow servant.

2. Where a street car was off the track, and the superintendent of the road called on employees standing by to assist in replacing it, and a motorman leaves his car, without setting the brakes, and, it being on a down grade, runs away and collides with another car, the negligence causing the accident was that of the motorman, and not of the superintendent.—(Hoover vs. Carbon County Elec. Ry. Co., 43 Atl. Rep., 74.)

Improvements at Celoron

The Jamestown Street Railway Company, of Jamestown, N. Y., serves one of the best equipped pleasure resorts in the country. This is at Celoron, on Chautauqua Lake, and is owned by the Celoron Amusement Company, a company composed largely of the same gentlemen owning the street railway lines. George E. Maltby, general manager of the amusement company, and also general manager of the Jamestown Street Railway Company, writes as follows concerning Celoron:

"Regarding the improvements at Celoron, we, like all other amusement companies, are obliged to keep fresh and attractive things before the public. This year we have changed the color of all our buildings, making them snow white, as well as the large boulders, which beautify the grounds. We have also added the Paul Boynton's "Trip Down the River," ours being, I understand, the only one in this country outside of Coney Island. We also have with us the miniature train that was at the Omaha Exposition. This is certainly an attractive feature, having a miniature engine propelling six coaches, each containing two persons, the engineer sitting on the tender, and firing his engine with hard coal. We also have a school of trained seals.

"We opened on May 29 with a good company for two weeks. The third week we had refined vaudeville show; fourth week, minstrels, opening up the week of July 3 with a comic opera company for four weeks. From this on, completing the sixteen weeks which we are open, our opera house will be pleasingly filled with the best talent which we are able to procure. We have found, as, no doubt, all others have in this line of business, that refined entertainments are the only kind which attract and draw. People will not follow entertainments that are vulgar, and it is impossible to succeed by permitting them on your stage.

"We have also given a series of animated pictures and stereopticon views; for instance, on one evening we gave a set of views of Germany; on another evening, France; then England, then Switzerland, and then views of interest in the United States. We did this for the purpose of attracting and entertaining the people on the grounds, and it is barely possible that we shall give a series of the "Passion Play," animated pictures as well. These, you understand, are entirely free, and are simply to attract those who may remain in the evening. Of course, we intermingle balloon ascensions, high dives and rowing contests, and everything of interest to the public.

"From a financial standpoint, we must say that our enterprise has been successful. Of course, we have quite a large investment, but believe that a park giving its patrons clean and wholesome amusements will financially succeed.

"For the week of May 29 we had a 'Wild West' entertainment. We are also figuring with the Banda Rossa for their famous concert some week in August, and will have several displays of fireworks at different intervals during the season."

NEWS OF THE MONTH

The Birmingham Railway & Electric Company has discovered a well organized movement to defraud the company on a large scale. It has been found that a number of the employees have obtained a large quantity of used tickets, which had been torn in half and thrown away. The two halves of the tickets were cleverly pasted together with a special glue, and the tickets were then sold three for ten cents.

The Market Street Railway Company, of San Francisco, recently replaced an old turntable at the end of one of its lines by one of more modern construction. The moving of the old turntable through the streets of the city was quite an undertaking, requiring about forty horses. The immense circular frame nearly occupied the width of the street in transit.

The Denver City Tramway Company has announced its intention of advancing the wages of all its employees in view of the fact that the court has recently decided the franchises are valid. Under the new schedule the men for the first year will receive 17½ cents an hour; the second, 20 cents; the third, fourth and fifth years, 21 cents; and thereafter 22 cents. This will place the Denver employees among the best paid street railway men in the country.

In the suit of the Mercantile Trust Company, trustee of two mortgages executed by the Denver Tramway Company conveying to the trust company certain lines of street railway, to restrain the corporate authorities of the city of Denver from repealing an ordinance under which the roads conveyed by the mortgages were constructed between 1885 and 1890, Judge Hallettt has granted the request of the plaintiffs and issued the desired restraining order. Notice of appeal has been entered by the city.

The Capital Traction Company, of Washington, has increased the wages of the men on the Cherry Chase branch from $1.60 to $2 per day.

The Court of Appeals, in session at Wytheville, has reversed the decision of the Circuit Court of Alexandria in the case of the City Council of Alexandria against the Washington, Alexandria & Mt. Vernon Electric Railway Company. The City Council adopted an ordinance requiring the railway company to lay grooved rails in King Street, between Fairfax and Royal Streets, which portion of the street was ordered to be repaved with vitrified brick. The railway company declined to comply with the terms of the ordinance relative to the grooved rails, and the corporation attorney was directed to institute mandamus proceedings to compel such compliance. Judge Nicol rendered a decision in favor of the city, and the railway company took an appeal to the Court of Appeals, which reversed the decision of the lower court.

Owing to an agreement recently signed it will soon be possible to ride all over the District of Columbia for a single fare. Switches and cross-overs will be built connecting different lines, so that the cars from one system can be transferred to the tracks of the other systems. One of the features of this arrangement will be the possibility of an extensive private car service.

A bill introduced in the Florida Legislature requiring street railway companies in Florida to provide separate compartments or cars for white and colored passengers recently passed the Senate, but did not pass the House of Representatives, and therefore did not become a law.

The Siemens & Halske Electric Manufacturing plant, which came into the hands of the Illinois Electric Vehicle & Transportation Company some time ago, is to be immediately fitted up for the manufacture of the company's vehicles.

The Savannah, Thunderbolt & Isle of Hope Street Railway Company has furnished all its employees with new summer uniforms. A new rule has also been put in force requiring conductors to be courteous at all times in their treatment of passengers, and ordering them to assist ladies and old persons on and off the cars.

It has been the custom for some time to turn the cars of the Rockford Railway, Light & Power Company over to the ladies of the city one day each year, and give the day's receipts to a charity fund. This was done on June 10, and over $1,000 was cleared by the Ladies' Union Aid Society.

It is probable that an appropriation will be made by the Common Council of Chicago to enable a committee consisting of three Aldermen and two engineers to make a very careful investigation of street railway problems in other cities during the summer vacation. It is intended to have the committee examine and report upon the systems in Boston, New York, Washington and other American cities, and also in England, France, Germany and other European countries.

An order has been issued by the South Park Board of Commissioners, of Chicago, forbidding automobiles the use of the parks and boulevards within its jurisdiction. The reasons given are the illegal speed at which horseless carriages are often run, and also the frightening of horses and the consequent danger from runaways.

The Madison Electric Light & Street Railway Company, which has been employing woman conductors for over a year, reports that it is well satisfied with the service given by them, and does not intend to return to men conductors.

The Indianapolis Street Railway Company has advanced the pay of conductors and motormen one cent an hour. Employees for the first three months will receive 15 cents an hour, for the second three months 16 cents, and after that 17 cents.

Judgment against the New Orleans Traction Company in the sum of $429,246.62 has been given to R. M. Walmsley, John C. Russell and E. W. Clark, Jr., this amount being the balance left unpaid, with interest, legal expenses, etc., on $1,500,000 of trust notes on which the company defaulted as to interest, and the collateral securing, which brought but $1,200,000 at its sale.

The street railway companies of New Orleans, in view of the attempted enforcement of an ordinance requiring them to provide seats on all cars for conductors and motormen, have sent a communication to the City Council stating that it is impracticable under present conditions to manage electric cars safely if the motormen and conductors are permitted to sit down while performing their duties.

As the result of a serious rear-end collision which occurred some time ago on the Riverview Park branch of the United Railways & Electric Company of Baltimore, the cars of the system will be equipped with a rear oil signal lamp. The accident in question was caused by the stopping of a car, due to the untying of the trolley rope by a passenger on the back platform. The trolley pole jumped the wire, and in the darkness the conductor was unable to find the trolley rope in time to avoid the accident.

Through the courtesy of R. S. Goff, president and general manager of the Globe Street Railway, the inmates of the Old People's Home at Fall River were recently given a trolley outing to the company's pleasure park.

Fifty new cars are being constructed in the shops of the Detroit Electric Railway Company. Of these twenty-five are open and twenty-five closed.

The directors of the Fitchburg & Leominster Street Railway Company held their annual dinner on June 8, and their guests were, as formerly, members of the newspaper fraternity. Dinner was served in the hotel at the company's pleasure resort at Whal-

com. After the dinner the hotel and the grounds were carefully inspected, and everything was found in excellent condition.

The Consolidated Street Railway Company, of Grand Rapids, has made a reduction in the fare from Grand Rapids to Reed's Lake and North Park. This has formerly been seven cents, but it is now reduced to five cents.

A bill has been introduced in the State Legislature of Michigan making it legal for the street railway, gas and electric light companies in the State to consolidate their interests.

There seem to be indications that a severe rate war will be carried on near Detroit. In order to meet the competition of the electric railway company, and if possible force it out of business, the Flint & Pere Marquette Railroad will run a regular semi-weekly excursion train from Northville and Plymouth at 25 cents for the round trip. The regular rate has been $1.55. The electric railway fare is 70 cents for the round trip from Northville, and 60 cents from Plymouth.

The street railway employees of Detroit have asked the companies to increase the wages of conductors and motormen to 25 cents an hour. The officials do not wish to make any change in the wage scale until the municipal ownership agitation is settled definitely.

A temporary injunction has been secured restraining the Detroit, Ypsilanti & Ann Arbor Electric Railway Company from running its cars faster than 12 miles an hour in the city of Ann Arbor.

Among the bills introduced into the Legislature of Michigan is one providing for the equipment of cars over 20 ft. in length with air brakes.

At a meeting of the City Council of Duluth on June 12 a resolution was passed appointing a committee to confer with the Lakeside Railway Company, with a view to the purchase of its line by the city.

At the recent annual meeting of the Metropolitan Street Railway Company, of Kansas City, it is understood that Armour interests of Chicago came into the control of the property. The earnings for last year were at the rate of 7½ per cent on the capitalization.

The general offices of the St. Louis & Suburban Railway Company are to be removed from the Wainwright Building to the De Hodimont station.

The South Orange & Maplewood Traction Company is considering the advisability of putting automobiles in service in Orange between the Orange Music Hall and the terminals of the company's lines in Main Street.

A suit brought some time ago by the city of Bridgetown against the Bridgeton & Millville Traction Company has just been decided in favor of the city. The city had entered suit to compel the traction company to operate its cars on certain streets, the service having been discontinued on said streets when the Board of Freeholders removed the rails from one of the bridges on the route.

The Brooklyn Rapid Transit Company has furnished to the New York Stock Exchange a statement, showing that it holds in its treasury $40,449,828 par values of stocks, bonds and accounts receivable of the underlying companies. The mileage now controlled is 482.2. The assets amount to $46,433,951, as against a capital stock then issued of $38,770,000 and bonds of $7,000,000. The surplus is $248,325. A detailed financial analysis of the property was contained in the STREET RAILWAY JOURNAL for June, 1899, page 370.

A gang of robbers was interrupted while breaking into the safe of the Jamestown Street Railway Company at three o'clock on June 19, and succeeded in making their escape. The bandits had sandbagged the watchman, and were preparing to blow open the safe, when they were frightened away by a number of employees returning to work.

The third rail on the Brooklyn Bridge used for carrying the current for the elevated and bridge trains became loosened from the insulators one day recently and fell to the ties for a long distance. The accident, which was caused by a defective contact shoe, interrupted traffic for several hours.

It is stated that all the employees of the principal street railway companies in Greater New York have secretly formed an organization under a charter from the Knights of Labor.

The Middletown-Goshen Traction Company has made an advance in the wages of its employees, from 14 to 15 cents an hour, and from 12 to 15 cents. The company recently had a spotter on the road for about a week, and as a result about eighteen motormen and conductors were ordered to report to the office for various reasons.

The Ithaca Street Railway Company recently posted in the car barn a notice cordially thanking the employees for their conduct and excellent work on Decoration Day, when the company carried the largest number of passengers in its history.

Two of the double-deck trolley cars for use on the Syracuse, Lakeside & Baldwinsville Railroad were put into service recently.

C. L. Rossiter, president of the Brooklyn Rapid Transit Company, has announced that the management has under consideration an advance in the wages of all the employees of the system.

The Canton-Massillon Electric Railway Company has voluntarily advanced wages of conductors and motormen to $1.75 per day. The old rate was $1.60 per day. For extra time the men will receive 16½ cents per hour.

The city electrician of Cincinnati has recommended in his annual report that all electric wires in the city be placed under ground, including the electric light and street railway wires. If this is done it will necessitate the removal of 15,000 poles, about 275 miles of feeders and 75 miles of trolley wire.

It is stated that the system of the United Power & Transportation Company, recently formed in Philadelphia, will be operated by water power from the Schuylkill River.

A funeral trolley car service will soon be inaugurated in Wilkesbarre.

A dozen masked men entered the car barn of the Fairmount Park Transportation Company, of Philadelphia, on June 19, and, after capturing and binding six of the employees, blew open the safe with dynamite and robbed it of nearly $4,000. The robbers got away.

A defective journal caused a serious accident at Pawtucket on June 1. The car was running at high speed, and when the journal broke, tipped completely over, injuring the motorman and conductor, the only occupants.

The employees of the London (Ont.) Street Railway Company have been on strike for some time, and there is no immediate prospect of a settlement. The company's cars are running, but the public has quite generally boycotted them.

The Montreal Street Railway Company, on account of the increased receipts of the road, has decided to greatly better the condition of its employees, and a new schedule of wages has gone into effect. The schedule is $25,000 a year higher than previous

years. Conductors and motormen between their second and fifth years will receive $34 a year more than they are now getting, and after the fifth year will receive $49 more. The company has also started an insurance fund, which it will maintain at its own expense. Disabled employees will receive a weekly amount from this, and at death $1,000 will be paid to the estate of the deceased. Motormen and conductors have formerly paid two-thirds of the price of their uniforms, but the company has now made arrangements by which they will pay but one-half.

The American Railways Company, which was organized some months ago, and of which A. A. McLeod, formerly president of the Reading Railroad, is the leading spirit, is negotiating for the purchase of the Consolidated Traction Company of Pittsburgh. It is reported that 40 is being offered for the common stock and 70 for the preferred stock, payments to be made in 5 per cent collateral trust bonds of the American Railways Company. The latter is also negotiating for the purchase of the Philadelphia Company, which owns nearly all of the Pittsburgh United Traction Company's stock, and of the Pittsburgh Gas Companies' stock, and the price offered for the Philadelphia Company's stock is said to be 97½ per cent, or $48.75 per share. The details of these two purchases are not yet completed, however, and the above prices represent current rumors. The American Railways Company formally announces its acquisition of the Bridgeton Electric Company and the Millville & Bridgeton Traction Company, which latter company owns the entire capital stock of the Bridgeton Rapid Transit Company, the Bridgeton & Deerfield Turnpike Company and the Bridgeton & Millville Turnpike Company. Other companies said to have been acquired by the American Railways Company are the railway and lighting systems of Springfield, Ohio, and similar properties in a Southern city.

The International Car Wheel Company has been incorporated under the laws of New Jersey, with a capital stock of $15,000,000. It includes a number of important firms in the Northeast and Canada, among them being the New York Car Wheel Works, with plants at Buffalo, New York city and Philadelphia; Swett Car Wheel and Foundry Company, Boston; Boston Car Wheel Company, Boston; Ramapo Car Wheel Works, Ramapo, N. J.; St. Thomas Car Wheel Company, Ontario, Canada; Hamilton Wheel and Foundry Company, Montreal; John McDougall & Co., Montreal; Weston Furnace Company, Manistique, Mich., and Pittsburgh Car Wheel Company, Pittsburgh, Pa. The temporary officers are: P. H. Griffin, president and chairman of the board of directors; T. G. Smith, vice-president, and Warren P. King, secretary and treasurer.

In a recently issued statement of the condition of the Electric Storage Battery Company, of Philadelphia, it is said that sales of the finished product for the calendar year 1898 amounted to $1,340,988, as against $1,026,926 in 1897, and that during the five months ending June 1, 1899, sales were $1,360,561, as against $314,498 in the same period of 1898. The company now owns five-twelfths of the automobile business controlled by the Electric Vehicle Company and the Columbia Automobile Company, through its ownership of $4,000,000 in the stock of the former and half of the stock of the latter. These two companies have united their patents and organized a manufacturing company called the Columbia & Electric Vehicle Company, for the purpose of manufacturing all parts of automobile vehicles, with the exception of the storage batteries, which will be furnished solely by the Columbia Automobile Company. The entire product of this new manufacturing company will be purchased by the Electric Vehicle Company, and sold by it to the various electric vehicle transportation companies now organized throughout the country.

The experiment of providing a 10-cent route to Brighton has been instituted by the Brooklyn Rapid Transit Company. There are already several 5-cent routes to this and neighboring resorts, but the officials of the company believe that many people will greatly prefer to pay a double fare and thus escape the annoyance of traveling on overcrowded cars. It would seem as if this plan could be worked to advantage in other large cities, and the idea might even be extended to smaller places by running a few cars as "specials" and limiting the number of persons carried to the seating capacity. This service, however, should be an adjunct to, and should not in any way interfere with the regular service.

Rumors of labor troubles in New York have been diligently circulated in Wall Street last month, to the effect that trouble was brewing among the employees of the Metropolitan Street Railway Company, but this turned out to be wholly untrue. The management of the Metropolitan Company is probably stronger in the respect and affections of its employees than is that of almost any other railway of the country, and it would be exceedingly difficult to foment trouble among them, particularly in view of the fact that they are now receiving high rates of wages, and have many collateral advantages through their connection with the company.

Albert L. Johnson, who has been until recently interested in a large number of American street railway properties, has been investigating the opportunities for investment in England during the past year, and in a recent interview says: "The project I have in mind is not primarily for London street traffic, but to bring the seashore within reach of the great mass of the population, just as Coney Island is brought nearer to New York by trolley lines. In other words, I want to make Brighton, 53 miles from Charing Cross, a suburb of London. I intend to make a proposition to Parliament and the County Council to establish an electric road from Brighton over a private right of way to the London city limits, and then, by some arrangement through the streets to the heart of the city. It is to be an underground trolley system, similar to the Fourth Avenue line in New York. It costs $1.50 to go by steam railway from London to Brighton, and the price prohibits the masses from reaching the seashore. I propose to carry passengers the entire distance for 12 cents, running a mile a minute."

Governor Stephens has finally signed the bill permitting street railway consolidations in the State, which has been for some time in his hands, and as a consequence it is practically certain that the remaining street railway properties of St. Louis not as yet purchased by Brown Brothers, of New York, will be brought into a general consolidation. These companies include the "Chicago Syndicate lines," seven in number, one of the most important and valuable systems in the city, the St. Louis & Suburban and one or two minor lines. The system will comprise over 400 miles of track, and a large sum, stated as $5,000,000, will be spent in improvements.

J. Edgar Leaycraft, one of the State Tax Commissioners, has briefly outlined the policy to be pursued by the commission in carrying out the provisions of the Ford law for the assessment of franchises. The commission will make its headquarters in Albany, and until August will devote itself to completing ordinary routine work. It is the intention to prepare a very comprehensive blank, to be ready in about six weeks. One or more of these blanks will be sent to every corporation, and its officers will be required to fill it out to the satisfaction of the commission. Where there are any suspicious circumstances connected with the information furnished, the commissioners will make a personal and thorough investigation, but otherwise they will not make any inquisitorial pilgrimage throughout the State. The commission will first take up the franchise assessment in those counties of the State where the tax books are closed earliest, and the work will be expedited in every possible way.

The United Railways & Electric Company, of Baltimore, has purchased a lot 2100 ft. x 900 ft., upon which it will build shops, car house and general office buildings for the entire system. The various shops and houses belonging to the different companies before the consolidation, and which are scattered throughout the city, will be abandoned, and all the repair and storage departments concentrated on the new property. The United system earned, gross, during the month of May, 1899, $32,500 more than for the same month last year.

The Problem of Elevated and Suburban Electric Railway Transportation.*

BY FRANK J. SPRAGUE

Rapid transit is the science of competitive railroading, and if by wheeled vehicles, ultimately reduces to a question of the proportion of weight upon the driving wheels. All other matters entering into the question for any given case and set of conditions, such as schedule speed, traffic capacity, extent of equipment, total investment, frequency of service, operating cost, and even safety and reliability of service, are incidental to and directly or indirectly dependent upon the adhesion of the driving wheels of the vehicles to the track.

The fastest possible car movement between stations can always, under equal conditions of equipment, load, grade and power supply be made by the vehicle which has the greatest percentage of weight on the drivers. Therefore, definite theoretical and practical limits exist for railroad schedule speeds under any given conditions, and the highest schedules in any case can only be made by a train system which preserves under all circumstances the specific characteristics of a motor vehicle with 100 per cent weight on the drivers.

In the present stage of development of rapid transit systems for urban, suburban and interurban service, where stations are close together, traffic much congested morning and evening, and yard and terminal facilities limited and costly, high schedule speeds are absolutely essential. How shall they be had?

There are three distinct and generic methods of railroad passenger transportation, as follows: The single car operating independently, the locomotive pulling trail cars, the multiple unit system, or aggregation of transportation units, each fully equipped, into trains and provided with secondary control.

The first received its great impulse at Richmond in 1887-8. Its history and characteristics as illustrated by the tens of thousands of cars in daily operation need no detailed description. Each car is a motor unit, with large effective driving weight, from 80 per cent to 100 per cent, equipped with hand control, but incapable of aggregation into trains with localized control. This system broadly includes all modern street railways.

The second is the locomotive system, following steam precedents, and dictated by the limitations of steam engineering, in which there is concentrated in a single unit the weight and power necessary to handle a train under given conditions. This locomotive idea has taken two forms, one of which copies one or other of the many types of steam locomotives, with such modifications as are permissible with electric motors, but which, despite the remarkable general progress of electric transmission, still finds comparatively few applications in actual practice. Notable among these are the B. & O. tunnel locomotive in Baltimore and the proposed equipment for the Central London Railway. Among the earliest, if not the first, of the large locomotives, is one of 1000-h.p. capacity, built by the writer and his associates for the North American Company about seven years ago. Another form of the locomotive may be described as the locomotive car, which consists of a car body of the usual form, arranged to carry passengers, with one or both trucks equipped with motors, and hence with the weight distributed over a considerable distance, and with, as in the other case, hand control provided at either end of the car. Such a one was experimented with by the writer on the Thirty-fourth Street branch of the Manhattan Elevated in 1886-7, where was used the first modern railway motor, and a special car was built about the same time which was to have had an equipment of two 75-h.p. motors on each truck. This was before the days when the Richmond road was built, and therefore before the modern advance in electric railroading. This type of locomotive car was used in the Intramural Railroad in Chicago during the World's Fair, and is now in operation on the Metropolitan and Lake Street elevated railways in Chicago.

A modification of this locomotive car plan has been more recently proposed, which consists in putting a locomotive car at each end of the train, passing the main circuits through all the other cars, and providing duplicate hand controls at each end of each locomotive car for the eight motors constituting their equipment. The system is absolutely untried, presents innumerable difficulties, and has about all of the defects of the locomotive system, but constitutes an acknowledgment of the utter necessity of greater weight on drivers and greater power for meeting the requirements of modern transportation.

In matters of transportation, the passenger's demand and the wishes of an operating manager are not always alike. The passenger requires for his convenience the most frequent time intervals, the shortest station waits, and the highest possible schedule speed. The railway manager is apt to concentrate loads, increase the time intervals, and let the passenger wait, but in so doing he may lose the passenger. With a locomotive car system this is the inevitable result, because otherwise the entire motive equipment would be kept in continuous operation at low economy and at great expense.

All these methods—the single car, the locomotive, the locomotive car and the doubling up of locomotive cars—fall short of meeting the requirements of a flexible railway system to be operated on a high schedule. The single high-power car, using all of its weight on the drivers, needs no commentary so far as ordinary application is concerned, but the methods proposed for the aggregation of cars and the handling of trains through the medium of a locomotive or locomotive car, or aggregation of hand-controlled locomotives occupying fixed positions, utterly ignore the possibilities of electric application and the advantages manifest in every car operated on the street. In some form or other this has been recognized for a number of years, and it occurred to a number of engineers that for increased adhesion and to provide more power with distributed weight motors could be distributed throughout the train, the mains carried through it, and the system governed by a controller at the leading end.

One of the earliest of these proposals was made before the Society of Arts in Boston in 1885, just prior to conducting experiments on the elevated railroad, at which time I contemplated the use of motors on each car or every other car and a pilot locomotive of car containing an adjustable controlling apparatus which could be made effective for handling one or more cars. This project, however, never reached fruition, and, of course, fell short of the possibilities. Much more seemed certainly feasible. The excuse for the last mentioned proposal is found in the evident engineering truth that if greater power is applied to a train, and a high percentage of the weight on the drivers utilized during acceleration, higher schedules with reduced strain were possible.

Considering for a moment a single car as a unit, and putting all the available power in the motors connected to each of the axles which space permits, it is readily possible to put on motor equipment which will develop over 20 h.p. per ton moved, and to use 100 per cent of the weight on the drivers. The possibilities of this unit, that is, using the entire weight of the car for traction, and all the power which can be put within the space permitted, is the limit, and absolutely the only limit of the possibility of the speed to be attained by an electric car. If now this unit is lengthened, that is, cars aggregated into a train, and the same ratio of weight on the drivers and the same horse power per ton is maintained, then it matters not what the length of the unit, identically the same schedules can be made with the train as with the single car.

The most effective train operation, however, requires something more than schedule speed, and it seemed that, considered from a competitive standpoint, and with the idea of gathering every passenger possible, the proper method of operating a railroad should be something as follows: Starting at the time of least traffic, to operate the smallest allowable unit at intervals determined by the ratio of the increased cost of operation to the increase of passenger receipts to be obtained by shortening the interval. Then, as traffic increases, to shorten up this time interval as far as is consistent with safety, then to increase the size of train unit while maintaining the same interval and high schedule to take care of the greater traffic.

It is said that smaller train units cost more to operate than larger ones. This is to a certain extent true, but against this is the simple fact that on the scale of wages paid on many railroads the difference in total cost between operating two two-car trains and one four-car train is one passenger per car for every fifty stations as spaced on the elevated railroads in New York. In view of this fact it can hardly be questioned that if shorter intervals are made possible then more passengers would be gathered than represented by these differences, and trains would, if a practical system were devised, be operated in any length from one car up.

These, I think I may fairly say, were the views which finally came to be held by such transportation authorities as Chief Engineer Wallace, of the Illinois Central Railroad, and Chief Engineer Cornell, of the Brooklyn Elevated, in the spring of 1897, and in this connection it is interesting to note a chronological review of various proposals which had from time to time been made for elevated railroad equipment and operation, which is appended to this paper, which will serve to illustrate a diversity of ideas and recommendations which have done much to bring ridicule upon the professions of electrical engineers.

This review is not intended to give a complete or detailed history of electric railway development, but is a running commentary on a variety of proposals made for train operation on elevated or suburban railroads from the year 1880 to the present time. A sur-

* Abstract of a lecture delivered before the American Institute of Electrical Engineering, on May 16, 1899.

vey of this record for the first seventeen years, up to and including the first proposals made as late as the spring of 1897 to the South Side road, shows that with the exception of proposals made by me at various times, beginning at the Society of Arts, in Boston, in 1885, and ending in definite proposals to the Manhattan Elevated Railway in 1896 and 1897, there were no propositions, or even a suggestion, from any manufacturing corporation or individual to equip a railroad on any other than a locomotive or locomotive car plan, with the single exception that on the Liverpool Overhead Railway two-car trains are operated as a unit, each unit having a motor disposed at the leading and back ends, and with a hand controller at each end. Typical important installations were on the locomotive plan pure and simple in 1895 at Baltimore, and on the locomotive-car plan, under the supervision of W. E. Baker, on the Intramural Road at the World's Fair in Chicago, 1893, and on the Metropolitan West Side Elevated Railroad, under the same supervision, in 1895, at the former of which Mr. Baker had to override recommendations in favor of a locomotive.

The variety of ideas indicated by these notes and the inexcusably wide divergence of expression concerning the commonest engineering facts, as well as the crudeness of many electric railway proposals, was never more sharply shown than in a paper by Mr. Wallace, of the Illinois Central Railroad, on the subject of "The Substitution of Electricity for Steam as a Motive Power for Suburban Traffic," before the American Institute of Civil Engineers, Feb. 3, 1897, and in the discussion which followed it. Mr. Wallace, having, in December, 1891, been directed by the management of the Illinois Central Railroad, of which he was then the chief engineer, to investigate the subject of adopting electricity on the Illinois Central Suburban Railroad, after a careful consideration of the requirements of the road, issued a list of forty-five categorical questions covering the operation of a fairly fixed equipment at 20 miles an hour. These questions were sent to all the various electrical companies except the Sprague, which had at that time been absorbed by the Edison General Electric Company. Consequently, for the Sprague Company and for myself I must disclaim any responsibility for the "mix up."

I will not attempt to review the answers to all the inquiries as presented by Mr. Wallace, but only touch upon a few of them, to illustrate the disparity of recommendations made, but for an interesting detailed comparison refer to the comments at the meeting by Charles Henry Davis, who began his remarks with a statement partly quoted from Mr. Wallace, that: "The engineers giving this matter their attention have been enthusiastic electricians; they have seldom been practical or expert mechanics, and the writer would add, usually inexperienced as railroad engineers."

But let us briefly take note of the recommendations. The motor capacity varied from 100 h.p., divided into four units, to 200 h.p., divided into two units, and distributed from one to two motors on each of two trucks under a locomotive car carrying passengers, or on, the other hand, aggregated into a locomotive pure and simple, without passenger capacity.

Both ring and drum armature construction was recommended, and driving wheels of from 30 ins. to 42 ins. diameter. About every possible form of axle driving, except chain or belt transmission, was proposed. One company was indifferent as to whether the motors were directly on the axles or gear transmission was adopted; another recommended spur gearing; another, cranks and parallel rods; and still another, no form of gearing under any circumstances, but an armature mounted on the hollow shaft surrounding the axle.

The central station equipment varied from 4800 h.p. to 18,000 h.p., and the steam units, from 400 h.p., driving single machines, to 1500 h.p., driving double machines. Horizontal compound and vertical triples had their advocates, and rope or belt as well as direct connection between engines and dynamos. The space required for the central station varied from 12,000 to 75,000 sq. ft., and the cost of power plant, not including real estate or buildings, from $320,000 to $1,169,000. Amount of fuel required per horsepower, from 2 to 3½ lbs. The annual cost of power plant operation ran from $60,000 to $225,000. The potential varied from 500 to 1000 volts. The cost of trolley lines and feed wires varied from $40,000 to $172,000, and repairs to the same and other line expenses, from nothing to $23.50 a day. The practical curvatures ranged from "50-ft. circle" to "150-ft. radius."

On one subject there was unanimity of agreement, the transmission was to be by continuous current, and by overhead trolley. Despite Mr. Wallace's request for information about a third-rail supply, it was incontinently waved aside. The multiple unit system was not in any form proposed, but there was discussion on the subject of the relative advantages of small independent units versus trains.

The recommendations made hardly need extended comment, and one can well imagine the reasons which stopped any then further action on the part of the Illinois Central Railroad. The whole paper is one of great interest, but from the discussion I will extract only a few comments which, in view of the immediate subsequent developments, are important.

Thomas C. Clarke, the past-president of the Society, stated as follows:

"The author, under the head of 'minor problems,' speaks of 'the size of transportation units and whether independent motors of large power shall be used to haul long trains of trailers, or whether small transportation units, run at more frequent intervals, shall be adopted.' with motors on the cars. In designing the rolling stock and structure of elevated electric railways in cities, this is the main point, and not one of minor consideration. Neglect to study this and to come to the correct conclusion has led to the financial failure of one of the largest electric elevated railways that has been constructed, and will lead to the financial failure of all others that follow the same lines.

"Carrying passengers in a city does not differ from any other business. The first requisite is to get abundant traffic; the second, to handle it with economy. Elevated lines run in competition with surface lines, and charge the same fare. The surface lines can beat them in all points but one. They afford more frequent stops; there is no climbing of stairs; cost of construction and, consequently, interest is less, and the system of transfers to branch lines is a great accommodation to the public. The elevated trains, not being impeded by surface traffic, can make better time; but for that, no person would ride in them, except to escape crowding.

"Common sense would indicate that the managers of elevated lines should try to approach, so far as possible, the conditions which have made surface lines a success. Frequent stops can only be attained, without losing too much time, by having a great power of acceleration. Any amount of power can be sent from the central reservoir, but if the wheels of the car slip, a limit is reached. Therefore, instead of having only one-third of the weight of the train available for adhesion, as is the case where an electric locomotive draws a train of trailers, utilize the whole weight of the train and passengers by putting motors on every car, connected electrically and mechanically, and worked by a motorman at one end of the train. Another advantage resulting from this is that gradients can be steepened, and the height of the station and their stairways reduced. If, in addition to this, short trains of light cars are used, the weight and cost of the structure can be greatly reduced, and the interest charges also. Small trains mean frequent trains to enable the traffic to be carried, and everybody knows there is no means of attracting traffic so powerful as that of frequent trains, as there is then no waiting at stations, which everybody hates.

"The summing up of the whole matter is, that to make city elevated railway a success, the surface electric system must be copied, and placed above obstructions from other traffic, and not the steam locomotive system of long trains at greater intervals. The process of evolution which develops everything along the fittest lines will make the city elevated railway of the future one of light structure, carrying light and very frequent trains, with motors on the cars themselves—a development of street trolley lines, and not of steam locomotive railroads."

Walter H. Knight said:

"The whole object of the elevated railroad is speed, and speed cannot be made with short headways. It would make little difference, as far as speed is concerned, whether the cars were all equipped with motors, or all the electric apparatus concentrated on one car."

Mr. Wallace stated that:

"One of the practical difficulties in the way of placing motors on each axle of the car and on several cars of the train, and coupling them up so that they can all be used and under the control of one motorman, is that, so far as the author's investigations have gone, there is as yet no perfect and adequate controller in use in the United States which will provide for the proper manipulation of more than two motors."

And his conclusions seemed to be that while a train system did not give that which was necessary, nothing had been presented to him in answer to all his inquiries and his painstaking research which gave him any promise of successful departure from his then existing method of operation.

There is small cause to wonder that the early project for electrically equipping the Illinois Suburban was for the time abandoned.

At the time when Mr. Wallace's paper was presented a committee, including himself and some other officers of the road, had been formed, with John Lundie as engineering secretary, and with a number of assistants, was making some further investigations as to the possibilities of electric application. A report was made about the end of the year, and accompanying it was a proposal from me to guarantee a 24½-mile schedule on the suburban service of the road, instead of the 18½, which was then being accomplished by steam, and if I am not mistaken, all further consideration of a locomotive pulling trailers was abandoned.

I think, as events have turned out, that with regard to the diametrically opposed views presented by Mr. Clarke and Mr. Knight, the former may well rest content with the position he assumed.

THE MULTIPLE UNIT SYSTEM

Such was the generally unsatisfactory state of electric railway development for all else than ordinary street roads in the spring of 1897, and the conclusions which I have already given, together with apparent advantages which would accrue, pointed unerringly to the necessity of the third generic system of railway equipment and operation, that which I have termed the *multiple unit system*, which is the most logical, and seems to me a finality in railroad development. It may be briefly described as a semi-automatic system of control, which permits of the aggregation of two or more transportation units, each equipped with sufficient power only to best fulfil the requirements of that unit, with means at two or more points on the unit for operating it through a secondary control, and a "train line" for allowing two or more of such units, grouped together without regard to end relation or sequence, to be simultaneously operated from any point in the aggregation.

For any given weight to be moved, whether it be in one or two cars, there is a certain capacity of motive equipment with which it is best to operate it under fixed conditions, and that is the motor equip-

ment which should be put on that unit, not something either larger or smaller, and then when more capacity is required, to simply add another unit of like character.

A unit may be a single car or a pair of cars, and the number of motors used whatever desired. The logical equipment is two motors for each car, and when so equipped the importance of some of the practical results is emphasized.

Among the advantages which such a general system when fully developed must possess, may be mentioned, first:

Similarity of Equipment.—This gives absolute flexibility of train operation. It insures like characteristics for trains, whatever the length, and whatever the combination of cars. The motor equipment is directly proportional to the number of car units. There is a practical fixed relation between the weight on the drivers and the total load, whatever the length of the train, and it is a matter of indifference to the motorman whether he is operating one car or any aggregation of car units in a train, for its characteristics are always the same.

Independence and Facility of Operation.—Each car being lighted, heated and braked independently, has independent movement in yards or car houses or on the tracks, wherever stored, and thus inspection, repairs and train combinations are facilitated. The head and tail switching characteristics of locomotive practice is entirely abolished. Trains in whole or in part can be reversed at any crossover, thus reducing the dead mileage and intensifying the car movement to meet the conditions of passenger movement. Cars can be added to or taken from a train in a third of the time that is possible with a locomotive system.

Where a system has main tracks with branches, car units for the different branches can be aggregated on the main line and then split at the junction, thus preserving the time intervals on the branches, but doubling the distance intervals on the crowded sections. The fullest use can be made of all sidings and tracks, wherever located, for storage, and in a large measure for inspection, which insures less dead mileage and useless returns, and effects concentration of car movement impossible where the cars must be stored in one place.

Increased Schedules.—Any required rate of acceleration or schedule speed up to the maximum becomes possible, thus giving the highest schedule with any given maximum, and the lowest maximum with any given schedule. A partial equipment may be made by equipping alternate cars, and this schedule later increased by additions to the existing equipment without changing its character. Local and express service can be operated with greater or less aggregation of motor equipments.

It has been suggested that with a locomotive system, when trains are reduced in length, and the service on the road is diminished the locomotive car can then increase the schedule, and that during the times of heavier traffic it still has capacity enough to pull a train.

Such an argument is a reflection on the common sense of a railway manager, and such practice a parody on railway operation. The time above all when schedule speed, capacity and effective operation are required is when traffic is greatest and the road most liable to congestion. It is difficult to see how any engineer can seriously offer such an argument in support of locomotive practice, for it is directly contrary to the most vital requirements on a railroad.

If, as is vital in competition service, a high schedule is necessary, and ignoring for the moment all questions about relative strains, weights, facility of making up and controlling trains, and the advantages of variable train lengths and intervals, when we come to six or seven-car train units a high schedule with short interval stations is impossible, except with two heavy four-motor locomotive cars or with every car equipped with a pair of motors. And, from every point of view, the latter is preferable.

Reduced Strains.—This is of importance where elevated structures or bridges are used, especially when already possibly strained. It is apparent that the weight of cars, truck and motive equipment between columns is necessarily less than with any locomotive or locomotive car system. All the longitudinal or shearing strains are greatly reduced.

The hammering on the rail joints, with the resulting shock to the structure and to the moving train, will be diminished because of the less weight per driver. The thrust strains for any given rate of acceleration are equalized and distributed over a considerable length of structure, and become practically the reverse of the braking strains. The strain on car bodies, platforms and couplers are reduced to a minimum.

Increased Density.—The safe time interval between trains for a given schedule and for any given length of train and station stop is dependent upon the maximum speed and the rates of acceleration and braking, and the greater these latter with any given schedule, that is, the lower the maximum speed and, consequently, the less the travel of the train after the brakes are applied, which distance varies roughly as the square of the speed at the time of applying the brakes, the shorter can be both the time and the distance interval between trains.

If there were an infinite rate of acceleration and braking, then there would practically be necessary, barring accidents, only that time limit between trains occupied by a train at and blanketing a station. In practice, a motorman will approach a station with more confidence and under closer headway when his maximum speeds are low, and the braking distance which he travels short, and when he has confidence that the train ahead, once started, will promptly accelerate and increase speed while that of his train is rapidly diminishing.

It is apparent, of course, that the length of a train is only limited by the platform accommodation.

Better Equipment.—From this standpoint better motor manufacture is insured. There are fixed limitations of wheel base, track gage, wheel seat, diameter of axles and distances between axle and bolster, and hence there are practical limitations to the outside dimensions of motors. The smaller the capacity of the machine put into that space, the greater the margin for increase of dimensions of the essential working parts, such as bearings, gears and commutators, and the greater the freedom for inspection. Likewise, also, is there greater space for the application of any kind of brakes, electric or mechanical.

Reduced Number of Cars.—With any given maximum hourly mileage the number of cars in service or on relay will vary inversely as the schedule. The advantage is further augmented by those already instanced, the concentration of car movements where most desired, and the storage of cars at the most convenient points, with consequent less dead mileage.

Simplicity of Operation.—The operation of the multiple unit system becomes the simplest. Every motor car or pair being a transportation unit, and every aggregation of such being, so far as the motorman is concerned, simply an extension in the length of the unit, without in any manner changing its character, the operation becomes almost automatic, a sort of second habit. Like hand and like train movement exists whatever the combination, and wherever the motorman is situated. The making up of trains, so far as electrical features are concerned, is as simple as coupling up an air hose. No main currents are carried from car to car, only small currents through reversible jumpers, and the electrical combinations are effected automatically, however the trains are made up and whatever the end relation of the cars.

Protected by the automatic features, a child of ten years can handle full-sized trains on regular service with less trouble so far as the electrical apparatus is concerned, and with less instruction than is required for the simplest form of air brake.

Ease of Inspection.—The train line and the main motor circuits being absolutely independent, and provision being made on any car for cutting out a set of motors, facility exists for an easy inspection whe ever the cars are located. Almost all the working parts of the motors can be inspected through the trap door in the bottom of the car, and since the cars have independent movement and can be rapidly run through an inspection shed over a pit, a little practice enables an inspector to make the most rapid survey of trucks, brake rigging, motors and everything else which is under a car.

Economy.—Transportation wages per car mile, the largest element of cost, are reduced because of the simplicity of operation, and because of the increased schedules. With the same efficiency, there is less power per car mile expended, and hence less coal burned, for any given high schedule with like conditions of traffic than with a lower rate of acceleration, because of the less amount thrown away in braking. The increase of power required because of low acceleration over high is anywhere from 25 per cent to 50 per cent.

When it is realized that a system like the elevated railroad would use only one-sixth of the power actually used now if it made no stops the importance of this fact may be seen.

The question of coal economy is of less importance, however, than many other features of railroading, and, from a financial standpoint, far less important than getting absolute freedom in determining train intervals and train lengths. In this connection it should be noted that altogether too little consideration is given to the question of car construction and car weights, and it seems to be forgotten by many engineers that useless tons of dead weight moved represent unnecessary investment in plant, and a continuous charge against operating expenses, and it is about as sensible to ignore this question as it would be to add pig lead to a car having all of its weight on its drivers to increase its traction. If half the gray matter was spent in reducing useless tonnage moved as there is in bargaining on the cost per kilowatt of apparatus, the cost per car mile and the ratio of operating expenses to receipts would be gratifyingly reduced.

Safety.—The highest safety is essential. In the case of fail-

ure of brakes or on slippery rails, the machines throughout the entire train can be safely reversed. The current input to the machines is automatically limited on each one to its safe capacity. In case an accident should happen to an operator, and he lets go of his controlling handle, the entire power is instantly removed from the train, and in case the controlling apparatus on the leading car should become disabled the train can be operated from either end of any other car. In fogs and on slippery rails a fixed schedule can be maintained more effectively because of the lower maximum speed, the less distance traveled in braking, the greater confidence in approaching a station, and the promptness of the leading train in getting away. On account of the reserve capacity of the machines it is possible to make up time in clearing a road, which is a matter of the gravest importance on a congested system. The automatic cutting off of current will have an important bearing in a not distant future when a Legislature is apt to, and should, prohibit the operation of a train with only one man in front unless there is some certain method of removing the driving power in case of accident to the operator. This is an instance of where a small thing, possibly determining the employment of several hundred extra men, has a vital importance.

Least Cost.—The multiple unit system means lowest first cost, as well as lowest cost of operatoin. This is contrary to first impression, but the explanation is simple in that the cost of the delivery of electrical energy to the car shoes per unit of constant use is eight to ten times the cost per unit of maximum capacity of car equipments, and by using the higher rate of acceleration rather than the lower for any given high schedule, the aggregate cost of the total equipment from power house to car equipments for any given hourly mileage is less, because, notwithstanding the increased cost of car equipment, the difference of economy creates a saving in that portion of the electrical equipment, that is generation and distribution, which costs so many times more per unit equipment than the units of car equipment, that the latter increase is more than made up by the saving in the former.

All this is readily proven, for I know of no problem presenting greater and more interesting possibilities of exact determination so far as results are concerned than that of electrical railway engineering; yet, on the other hand, I know of none in which there is a more reckless disregard of possibilities than in this very profession. In this, as well as in every other problem of kinetics or construction, and just as certainly as in the construction of a bridge, great increase of first cost and cost of operation may accrue from a disregard of the essential relations of all parts of the system, and on the other hand great savings may be achieved by a thorough knowledge of them. Despite these facts, it is curious to note oftentimes the inversion of the sound engineering with which the consideration of the electrical equipments of a road is often attended.

On any existing road whose traffic is known, the problem, put in the briefest form, should be: Given the existing maximum car mileage and schedule, how best and most cheaply, both as to first cost and cost of operation, most quickly and with the least interference with service, and without increase of strains on elevated structures or bridges, can the existing mileage be maintained, how much can it be safely increased, what possible schedules can be made, and what will be the effect on the traffic and operating expenses of the road?

The fact that there is a most intimate connection between the generating, transmission and the motor parts of the equipment seems often to be lost sight of entirely. The natural procedure would be to determine what results are desired, and then find the best method of getting them. Instead of that, oftentimes a purely empirical decision is made as to portions of the equipment, such as the capacity of the central station and size of its units, and the results so far as the movements of cars are concerned left to take care of themselves. This procedure reminds me of the architect who desires to erect a sky-scraper, deciding upon the foundation without regard to the weight of his building or the character of the soil beneath it.

There is, in fact, the most intimate possible relation, as should be perfectly evident, between the various parts of the equipment, and this relation is such that the cost of each part is seriously varied with exactly the same schedule, grade and load conditions by variations in the manner of making those schedules.

This is in no manner more effectively shown than in John Lundie's most interesting methods of detailing the essentials of first cost and cost of operation for various schedules under various rates of acceleration, all referred to a common factor, the percentage of weight on the drivers.

Such, then, are the practical advantages to be derived from a properly devised multiple unit equipment, but to be effective the details of the system had to be developed at great expense and much experience to a state of absolute reliability and reasonable simplicity. It may be stated, now, that the essentials of the multiple unit system are not complicated, despite the remarkable variety of functions which they have. They may be stated briefly to be as follows:

1. The master controllers on the platforms at each end of a transportation unit. They are of the simplest and most reliable character.

2. The master controller and train line cables, which become parts of the permanent wiring of a car, and are just as reliable and as simple as that for the lighting system. These secondary controlling cables are absolutely independent of the main motor circuits, and carry very small currents.

3. The jumpers, which are removable sections of the train line, connect the parts of the latter, which are permanent to each car, just as air hose couplings connect up a brake line.

4. The main controller, which is composed of the following parts: (*a*) certain relays and a throttle, developed in electric elevator service; (*b*) pilot motor with automatic limits, something like that used in elevator controls, but of more robust make; (*c*) a rheostat cylinder, with or without motor grouping switches, the parts similar to those of hand control; and (*d*) a reverser with like parts, but independently operated.

The braking system, whether using automatic air or electric, is something like the multiple unit electric system. There is a train line with means at each end of each transportation unit for simultaneously applying the brakes. When automatic air is used there is a train and equalizing line, a compressor with an automatic governor, illuminated gages, and a simple form of engineer's valve at the ends of each car for each transportation unit.

RESULTS OF THE MULTIPLE UNIT EQUIPMENT ON THE SOUTH SIDE ELEVATED RAILWAY

[Here follows a complete technical description of the installation of the Sprague multiple unit system on the lines of the South Side Elevated Railway Company, the substance of which has already appeared from time to time in the columns of the Street Railway Journal.—Ed.]

The financial results of operation on the South Side Elevated Railway are as follows, the months of November and December, 1897 and 1898, being the first strictly comparative months:

In addition to all "loop" expenses there is a rental charge equal to 10 per cent of the gross passenger receipts of the road. This should be considered really as an interest charge, not as an operative expense.

For these two months, with an average of 489,979 car miles on the main line, the comparative table following shows:

(*a*) Ratio of expenses to earnings, *including* "loop" rental, taxes and licenses;

(*b*) Ratio of expenses to earnings, *excluding* "loop" rental, but including taxes and licenses;

(*c*) Net earnings.

	(*a*)	(*b*)	(*c*)
November, 1897, steam.....	87.3	77.7	$10,603.80
November, 1898, *electric*.....	57.3	47.7	39,448.56
December, 1897, steam.....	83.6	73.8	14,691.69
December, 1898, *electric*.....	55.0	45.4	45,355.68

The succeeding months show increasing traffic and equally favorable results.

The operating expenses per car mile during November, 1898, on the main line, including and properly apportioning to it everything except licenses, taxes and rental, were less than 7½ cents on an average and maintained schedule of 15 miles an hour, with stations 2080 ft. apart.

So much for the actual results accomplished on the South Side road. The question naturally arises: Have there not been difficulties, and if so, of what character?

Of course there have been, and I should have been surprised, and almost sorry, if it had been otherwise, because it is only through the difficulties incident to the earlier operation of a system of this character that the essentials are fully determined and apparatus developed to a state of perfection. It is curious, however, that there have been more troubles with what is classed as "standard apparatus" than with that individual to the multiple unit control. These latter troubles were, first, with the rheostats, which were of new construction, and later, poor brush terminals, cracked gear cases, and with the earlier type of air governors.

With the specific multiple unit apparatus the principal troubles were with poorly and hastily wound relay coils, too light and unsubstantial construction of auxiliary contacts, and improper jumper construction, causing an occasional opening of the controlling circuits.

Taken all in all, however, the president and superintendent of the road state there were less troubles than when starting with their compound locomotives, and on the whole the success of the road has been unparalleled in electric railway history where so radical a departure has been taken.

ESTIMATES OF SAVING ON MANHATTAN RAILWAY, NEW YORK

Coming to New York conditions, I may say that, based upon the Chicago performance, and allowing for difference of coal cost, the Manhattan road, now operating at 12½ miles actual schedule during time of actual load, and making about 43,000,000 miles annually, can be operated at over a 16-mile schedule at not exceeding 9 cents, instead of 11.9, and on the existing mileage this would mean a saving, excluding interest on investment, of about $1,250,000 per annum, or, allowing interest on investment, of about $750,000, to say nothing of any other gains. A 17-mile schedule can actually be made with two motor equipments.

In closing, perhaps I may venture an opinion as to the general features which should characterize a suburban passenger railway equipment. I think it may be safely stated that the first is the use of the continuous current in the motor equipment, in spite of the claims which have been made and the results accomplished with alternating current motors, at least so far as we can judge by any present developments.

The problem, then, is whence shall be derived this continuous current, and that depends upon distances. For moderate distances, continuous current generators supplying current directly to the line, with or without the addition of storage batteries, are preferable. When the extent of the line becomes at all serious, then it must be considered as made up of a number of shorter sections joined together, each of which derives its principal source of supply from a local station, which station can be driven directly by water or steam power, or by an alternating current from a distant station, using a motor-dynamo combined in a single type of machine, the rotary converter, or joined in the form of a directly coupled set, the dynamo end being for continuous current and the driver a synchronous or induction type of motor.

Generally the sub-station should be supplemented by a storage battery, to take care of fluctuations in the load, to make even the duty on the sub-station and as far as possible at the central station, and to take care of some portion of the peak load caused by abnormal variations in the aggregate service at different times of the day. Of course, with the storage battery comes the necessity of a means of some kind of automatic regulation; there are various methods, but I will not enter into them here. Looking forward, however, to a perfectly assured future of a heavy service over considerable distances, I may state that the general equipment of such a road should generally involve the following essentials:

1. High potential alternating current transmission from one or two well-placed central stations, with or without static transformers.
2. Motor-dynamo sets, or rotary converters, at a number of conveniently placed sub-stations, to convert high pressure currents into continuous currents of about 600 volts' pressure.
3. Storage batteries of quick charge and discharge capacity at the same sub-stations as the motor converters to equalize their duty and to prevent sharp variations in the generating plant, as well as the sub-station.
4. A system of feeders and main conductors.
5. A power rail or trolley wire supplying continuous current, but ordinarily without any switching of currents.
6. Individual transportation units with a multiple unit control, so that combination of cars without regard to sequence or end relation can be made up at any portion of the line independently, and controlled from any selected point.

Chronology of Modern Electric Railroad Operation

Accompanying Mr. Sprague's paper on the "Multiple Unit System," read before the American Institute of Electrical Engineers, on May 16, was the following interesting chronology of modern electric railroad operation from 1880 to 1899.

1880.—Edison built and ran at Menlo Park an electric locomotive, and subsequently designed some others.

1883.—Daft, at Mt. McGregor, ran the Ampere, pulling one car, and Field, at Chicago, the Judge, also pulling one car.

1884-5.—Vandepoele, at Toronto, and later in 1885 or 1886, at Minneapolis, pulled trains of cars with an electric locomotive.

1885.—Daft, at Baltimore, operated a locomotive and trail car, subsequently increasing the equipment, and on the elevated road pulled a train with an electric locomotive for experimental work.

DECEMBER, 1885.—At Society of Arts Sprague stated some of the possibilities on the elevated railroad, and pointed out the advisability of putting motors under each.

1886.—Sprague built the first locomotive car. This was intended for experimental work on the elevated road, but was abandoned before the motors were completed.

1886.—About this period the Rhode Island Locomotive Works, under direction of Knight & Bentley, designed a locomotive for rapid transit train operation, but it was not built. About this same time Stephen J. Field designed an electric locomotive for the same purpose.

1886-87.—Sprague operated a standard elevated railroad car with two single reduction motors axle centered, and with one end spring supported from the truck body, on the Thirty-fourth Street branch of the elevated railroad, and also pulled a trail car, and prior to this, a platform car, with the same motors, in the Durant sugar refinery on Twenty-fourth Street, New York. This was followed by the Richmond equipment, the beginning of the modern development.

NOVEMBER 4, 1890.—City & South London Road opened. Originally designed for cable. Light trains operated by electric locomotives having two gearless motors with the armatures rigidly mounted on the axles of drivers.

1892.—Sprague, Duncan & Hutchinson designed, afterwards building it, a 60-ton electric locomotive for experimental work in connection with the North American Company. It was not put to use.

FEBRUARY 4, 1893.—Liverpool Overhead Railway. Operates two-car trains, each car having one motor disposed at the leading and back ends of the couple, the two cars being kept together as a unit. Hand control at each end.

SPRING OF 1893.—Under the general supervision of W. E. Baker, assisted by B. J. Arnold, in charge of the steam plant, and Charles H. Macloskie, in charge of the car equipment, the Intramural Railway was constructed at the World's Fair. The General Electric Company was largely interested in this enterprise. Four-motor cars, with hand control, were used to pull three trail cars, this plan of distributed motors under the passenger car having been advocated by Mr. Baker in opposition to the general opinion then in favor of electric locomotives. The third-rail supply, with the flexible sliding contact shoe, was here used for the first time, and the road may be said to be the first real practical train operation on any serious scale in this country.

NOVEMBER 3, 1893.—The General Electric Company's engineers, in a communication to Col. Hain, general manager of the Manhattan Elevated, recommended eight-car trains to be pulled by a single 40-ton, four-motor car, guaranteed an increase of 14 per cent in schedule, and stated that the motor car could pull thirteen-car trains as easily as present steam locomotive could pull five cars.

Proposed potential of about 600 volts, direct supply, unspecified number of stations, and did not suggest alternating currents, boosters or storage batteries.

MAY, 1895.—Metropolitan West Side Elevated Railroad equipped under the supervision of W. E. Baker, and using General Electric Company's apparatus, opened on locomotive car plan, using two motors on locomotive cars. This was the first commercial elevated road put into operation in the United States.

JUNE 27, 1895.—First of three 95-ton locomotives put in operation in Baltimore, by General Electric Company, for pulling freight and passenger trains through B. & O. tunnel.

SEPTEMBER 20, 1896.—Lake Street Elevated Railroad, which had been operated since October, 1893, with steam, began electrical operation, plans similar to those on the Metropolitan.

FEBRUARY 1, 1896.—(Daily paper.) Electric Storage Battery Company, of Philadelphia, described and proposed a storage battery locomotive to pull trains, storage batteries to be used in combination with current from third rail.

FEBRUARY 8, 1896.—(Daily Paper.) Sprague, in reply to strictures on the capacity of electric motors, in a daily paper, offered, under $50,000 forfeiture, to equip a train which could be pulled by a locomotive car, and also by motors under each car simultaneously controlled, and to make a speed of 40 miles an hour on express service.

APRIL 17, 1896.—In interview in daily paper, Westinghouse, on behalf of the Westinghouse Electro-Magnetic Company, with what was called the Westinghouse Wheeless system, proposed for all elevated and suburban roads the use of a contact pin system and the continuous current. At the same time it was stated that in ten days public demonstration was to be made to demonstrate success of the Tesla alternating current motor for this purpose.

JULY 16, 1896.—Exhibition of contact pin system for the benefit of Manhattan Elevated officials.

JUNE 6, 1896.—Sprague proposed to Messrs. Gould, Sage and Galloway, special committee of Manhattan Elevated, to make demonstration equipment of multiple unit system.

MAY, 1896.—Nantasket Beach Railroad put in by the N. Y. & N. H. R. R., under the supervision of Col. Heft, was opened—used General Electric apparatus and a locomotive car carrying passengers and pulling a trail car.

November 29, 1896.—Under the supervision of C. C. Martin, electric service was instituted on the Brooklyn Bridge Railroad. Twenty motor cars, each equipped with four General Electric Company 62½-h.p. motors and hand control, replaced the steam shifting engines, and were used in connection with the cable.

December 10, 1896.—The General Electric Company, through its Western office, proposed to the South Side Elevated Railroad an equipment of three and four-car trains, one of which should be a locomotive car having two motors, and six-car trains, one of which should be a locomotive car having four motors, guaranteeing that on the first combination 35 miles an hour could be made, and on the second 45 miles an hour between stations 2000 ft. apart. No central station system was described, either alternating or continuous, nor any potential determined.

December 10, 1896.—The Walker Manufacturing Company proposed to the South Side Elevated Railroad a system as follows: Continuous current, station in middle, pressure 600 volts, three and four-car trains, one being a locomotive car having two 125-h.p. motors, and guaranteed to save seven minutes in the trip from Congress Street to Sixty-third Street, a distance of about 8½ miles, that is, to make a schedule of nearly 19 miles.

February 14, 1897.—Sprague again stated the possibilities of the multiple unit system to the Manhattan Road, and again offered to make a demonstration equipment and to work up to eight-car lengths under every possible condition.

February 25, 1897.—Sargent & Lundy reported on general equipment for South Side Road, giving summary of locomotive car proposals and their recommendation, one of which was to double up trains.

February 26, 1897.—Potter, engineer of the railway department of the General Electric Company, reported to the third vice-president at Schenectady his recommendations of a system for the Manhattan, with details as follows:

Direct current,three-wire system, the cars on one track being in series with those on the other, 650 volts on each line, and 1300 volts between power rails on the two tracks, the track rails to be used as the neutral wire; two power stations equipped with 2300 kilowatt generators, direct current supply; five-car trains to be pulled by a single motor car with four motors; possible boosters or storage batteries at South Ferry alone; no alternating current, no sub-stations proper, and no storage battery regulations at sub-stations.

About the same date, a system diametrically opposed in almost every essential was proposed and recommended to the general contractors for the Central London Railway, by Mr. Parshall, of the British Thomson-Houston Company, with the General Electric Company in consultation as sub-contractors.

This proposition opposed the three-wire system, and on about 6 miles of road, recommended alternating current machines, four sub-stations with rotary converters, no storage batteries, five-car trains pulled by electric locomotives pure and simple, instead of locomotive cars. The locomotives are now being built and weigh 45 tons each. The schedule is moderate, and acceleration and braking are aided by having the station at peak grades of from 2 to 3 per cent.

The Westinghouse Company made proposals of something the same nature and the Siemens-Halske also, but the latter proposed the three-wire system, one track being in series with the other.

March, 1897.—Sargent & Lundy issued general specifications calling for alternative proposals for:

Thirty-six locomotive cars each having four 125-h.p. motors.

Forty-five locomotive cars each having two 150-h.p. motors.

One hundred and twenty motor cars each having two 35-h.p. motors.

April, 1897.—General Electric Company, through W. B. Potter, engineer of the railway department, proposed to the South Side Elevated Railroad four and five-car operation, one car being a locomotive with four motors.

April, 1897.—Westinghouse Electric & Manufacturing Company proposed to South Side Elevated operation of five-car trains, one being a locomotive car equipped with four 125-h.p. motors, and guaranteed to make an 18-mile schedule.

April 7, 1897.—Sprague, as consulting engineer, condemned the locomotive car system for South Side road, and recommended the adoption of the multiple unit system.

April, 1897.—Messrs. Sargent & Lundy, after report by Sprague, abandoned the locomotive plans for the South Side Elevated, and fully endorsed the multiple unit system.

April, 1897.—Chief Engineer Wallace, of Illinois Central Railroad, stated that trains could be run in any length, from one to a dozen cars, and he hoped to be able to run them with a push-button.

April 17, 1897.—Sprague tendered to the South Side Elevated Railroad a proposal to equip 120 cars on multiple unit system.

May, 1897.—Chief Engineer George B. Cornell, of the Brooklyn Elevated Road, stated that two essentials of his endorsement of any change from steam to electricity on that road were increase of schedule speed and a control which could enable him to run single cars or any desired aggregation of cars into trains.

July, 1897.—Short, for Walker Manufacturing Company, proposed locomotive car operation on Brooklyn Elevated Road.

July 16, 1897.—Sprague made demonstration at Schenectady of two-car multiple unit train, and ten days later of six-car train.

November-December, 1897.—Sprague made working test of multiple unit train on Metropolitan Elevated of Chicago of five-car multiple unit train.

Fall of 1897.—On the Brooklyn Elevated Railroad the General Electric Company's engineers recommended for a 15-mile schedule four and five-car trains, two of the cars being locomotive cars, each weighing about 35 tons, and equipped with four motors, with through connections of the main circuits, so that either the four or five-car unit could be operated from either one of the locomotive cars from a hand control. No independent operation of other cars was proposed. An alternating current central station, with sub-stations, rotary converters and storage batteries were also recommended.

1897.—Short, for Walker Manufacturing Company, proposed locomotive car plan for Manhattan Elevated.

December 23, 1897.—Sprague Electric Company sent the Illinois Central Railroad Company on specifications of John Lundie, the consulting engineer, a bid for an equipment for the suburban service of the Illinois Central Railroad, to use direct current system, with storage battery equalizers, individually equipped cars, multiple unit system, and to make a schedule speed of 24½ miles with stations averaging 2900 ft. apart.

December 23, 1897.—On same specifications, General Electric Company made similar bids to the Illinois Central, under agreement to get controllers for same from Sprague Company, in case their bid should be accepted.

January 12, 1898.—Mr. Sprague proposed to Mr. Gould to operate any combination of from one to ten cars under any conditions of rail on multiple unit system.

February 18, 1898.—Sprague tendered to the Brooklyn Elevated Railroad the multiple unit system. For temporary use, twenty-four equipments were consolidated on twelve cars to be used first as locomotive cars, and afterwards to be distributed.

The motor equipments were to be designed for 17-mile schedule, with existing station intervals.

Those on the South Side were designed for a 15-mile schedule, but make 16½ miles at times, with longer intervals.

February, 1898.—The General Electric engineers offered to supply on the first twelve cars actually equipped by the Brooklyn Elevated Railroad, motors with either hand or semi-automatic control, and proposed to supply four or five months later, when developed, a full multiple unit control.

April 20, 1898.—Sprague began operations on South Side road with multiple unit system.

June 18, 1898.—Sprague began operation on the Bridge end of the Brooklyn Elevated road.

July 12, 1898.—Waterloo & City, London. Straight run 1½ miles, no mid-station. Operates light four-car train units, the two end ones being motor cars with two motors, and the intermediates being dead cars.

July 27, 1898—Multiple unit system in full operation on South Side road, and steam abandoned.

Equipment on South Side road afterwards increased to 180 cars, 150 of which are fully equipped, and thirty for emergency service, partially equipped.

November 1, 1898.—Westinghouse Company began to put twenty cars on the Kings County Elevated Railroad, each equipped with two sets of two motors with controllers actuated by air pistons and controlled by a secondary electric circuit. Four only out of the twenty cars are in use at present and for locomotive purposes.

1898.—General Electric Company proposed six-car trains and double locomotive cars for the Manhattan Elevated, and three-car trains, with one single locomotive car, for the Boston Elevated.

And finally the engineers of the General Electric Company are credited with an intention to operate an experimental multiple unit train.

Of course, there are a number of other proposals which have been made both for multiple unit and other systems, and for various roads, of which, however, mention is unnecessary for the present.

Electric Traction on Tramways

Upon this subject, J. Clifton Robinson, M. Inst. E.E., A. Inst. C. E., managing director and engineer of the London United Tramways, Ltd., and the Imperial Tramways Company, Ltd., and engineer to the Bristol Tramways and Carriage Company, Ltd., read an interesting paper before the Cleveland Institution of Civil Engineers, of Stockton-on-Tees, England, May 29. The extent of the paper precludes its publication in this journal, but parts of it relating to the roads in which Mr. Robinson is interested, are given below.

BRISTOL TRAMWAYS

The Bristol tramways demand our attention as practically the first line in England where overhead electric traction was shown in its modern aspects. In the construction attention was seriously given to the provision of a solid roadbed, with heavy girder rails properly bonded, so as to secure a perfect return. The Board of Trade automatic recorder, now placed in the power house for the registration of any drop in voltage beyond the margin of 7 volts between any two points in the system, has commanded the most patient attention; and here, as in every line constructed subsequently under my supervision, this automatic record has remained from day to day and from hour to hour well within the margin.

The power station is located about the center of the present system. Its equipment has been extended and altered since the station was originally designed, and the two boilers have been increased to four; but they are all of the Lancashire type, and are fitted with Vicars' mechanical stokers, and one Green economizer in flue for the complete battery of boilers. The engine room contains four direct-coupled sets. Each unit consists of a 250-h.p. McIntosh & Seymour engine, driving one of the British Thomson-Houston type M.P. 6—150—200 generators. The total capacity of the station is 920 h.p. The engines are of the horizontal tandem compound type, with high-pressure cylinder 13 ins. in diameter; the low pressure 23 ins., and stroke 17 ins. The speed is 200 r.p.m., and the steam pressure 160 lbs. The economical load is 230 h.p. at one-third cut off.

In addition to the four traction generators there is a motor-generator which supplies current for the lighting of the station, and a negative booster for reducing the difference of potential on the rail return circuit. There are also four electric motors, of which two drive the feed pumps, one the mechanical stokers and fuel economizer, and one the machinery in the repair shops. Each of these motors will give up to 20 h.p. if necessary. The motor-generator is capable of developing on its secondary terminals an output of 230 amps. at 135 volts; its general construction is similar to that of the large generators. The motor portion of the machine is compound wound in such a manner that the e.m.f. at the secondary terminals is constant, but the compounding of the field is done entirely from the motor armature and not from the secondary armature, so that this latter may be used in connection with the accumulator battery. The primary terminals of the machine are connected to the main station bus bars, and have, therefore, to work at a potential of 500 volts. In connection with the shunt winding of the fields of the motor-generator there is a regulating switch with twenty steps and a suitable resistance, enabling the potential between the secondary terminals to be varied between 135 and 105 volts.

The total distance from the power station along the track to Staple Hill is 5.6 miles, and as there are usually about twenty-four cars distributed over this part of the system, there would be a drop on the return of about 9 volts, under these conditions. In order to diminish this drop and bring the operation into agreement with the Board of Trade regulations, a portion of the current is drawn from the rails by means of the negative boosters previously mentioned. This machine consists of a 500-volt motor, direct coupled to a separately excited, series-wound generator, having a maximum capacity of 300 amps. at 500 volts, on the terminals. The generator armature is connected in series with the negative bus bar through an insulated cable leading to the rails, while the field is in circuit with an insulated feeder connected from the positive bus bar to the trolley wire. It is instructive to watch the recording voltmeter in series with the test wire connected to the Staple Hill terminus, as the field of the negative booster is varied. The drop on this section with the booster cut out is 9 volts, and with the booster in, and with approximately zero potential on the rails, the drop is only 3 volts, or well within half the maximum limit allowed.

An armored feeder cable is laid underground the whole length of the line, and is connected about every half-mile to the cast iron section boxes containing switches and lightning arresters. In addition to the feeder there is a small three-strand insulated conductor laid the whole length of the system. One of these strands is for the Board of Trade leakage tests. It is only connected to the rail at the extreme ends of the line and at the power station to the Board of Trade panel. The other two wires are for telephones, an instrument being fixed in each of the section boxes for use by the company.

The trolley wires running from end to end of the line are of hard-drawn copper, 0.32 in. in diameter, and are divided by section insulators about every half-mile, where the two ends are brought to the switch boxes and joined to the feeders through the switches. Any section can thus be cut out, if necessary, without disturbing the traffic on the rest of the line.

The practical success of the early installation at Bristol has led the company to undertake the electrical conversion of all their lines, which amounts to some 50 miles. Work is also being vigorously pushed forward at the new central power station at St. Philip's Bridge, on the River Avon. The site is located advantageously in respect to coal and water. This station will be equipped with the highest type of plant and machinery, one unique feature being that the engine room is on the ground floor, and the boiler room vertically above.

The engines are of the vertical cross-compound Corliss type, with cylinders 22 ins. and 44 ins. x 43 ins. stroke, running at 90 r.p.m., and each has direct coupled a 500-kw. electric generator. The flywheels are 16 ft. in diameter and weigh 85,000 lbs. The steam consumption of these engines is guaranteed to be 12.7 lbs. of steam per i.h.p., with a mechanical efficiency of not less than 92 per cent. On account of the central location of the power house the distribution will be on the continuous current principle. The generators will be of the 10-pole type to generate 1000 amps. at 500 or 550 volts, as may be required.

The steel frame building will be 140 ft. long, 52 ft. wide and 93 ft. in height from the basement to the roof trusses; the basement being 9 ft. in height, the engine room 37 ft., the boiler room 20 ft. 8 ins., with an additional floor above the boiler room 15 ft. in height to contain the water tanks, coal storage bunkers, economizer flue, etc. A 25-ton electrically driven overhead crane will traverse the whole length of the engine room.

The boiler room will contain eight horizontal water tube boilers, each with the capacity of evaporating 8250 lbs. of water per hour, at a steam pressure of 160 lbs. Each furnace will be fed by an electrically driven mechanical stoker of the "Coking" type, and the ashes will be removed by the return line of the conveyor, and received into a tank outside the building, from which they can be drawn off into barges.

The coal supply will be received from barges by automatic shovels and delivered into a coal storage tank at the back of the building, from which conveyors of the noiseless gravity bucket type will deliver the coal into the bunkers above the boilers, and from these the supply will be drawn off for the furnaces through weighing hoppers.

The smokestack will be erected at the end of the boiler room, having 10 ft. clear inside diameter and being 200 ft. in height above the foundations. It will be built up of steel plates in rings lap-jointed and riveted, tapering upwards, and finished with an ornamental cap at the top. It will be entirely self-supporting, and will be lined throughout with firebrick.

On the floor above the boiler room there will be located the economizer, consisting of 360 tubes in thirty-six sections, and here also there will be two water tanks of 6000 gals. each.

The engine room will also contain two lighting sets, consisting of two two-crank tandem compound high-speed engines, running at 400 r.p.m., and each having direct coupled a 50-kw. 500-volt lighting generator, and three motor generators, each of about 40-kw. capacity, for use in connection with the rail return.

The condensing apparatus will consist of two surface condensers of the Admiralty type, each containing 3200 sq. ft. of cooling surface and located on the engine room floor. The air pumps will be of the vertical twin type, one set for each condenser. The circulating pumps will be motor-driven 8-in centrifugal pumps, one for each condenser. The condensing plant and auxiliary steam piping will be located in the basement. The boiler feed pumps will be of the vertical compound duplex type, and will be located in the boiler room.

The hot well will consist of a cylinder 96 ins. long and 48 ins. in diameter located in the basement; the water from this hot well being lifted to the water tank on the economizer floor by two electrically driven three-cylinder pumps.

The switchboard will be of white marble panels 8 ft. in height, bolted to angle-iron frames on a raised gallery at the bridge end of the engine room. It will consist of four generating panels,

two lighting generator panels, three booster panels, sixteen feeder panels, one lighting circuit panel and one meter panel; all complete with instruments and switches of the most approved type and design.

The system, including the St. George & Hanham Light Railway extension, when completed, early in the coming year, will have an equipment of 250 cars, and will prove in its organization to be one of the most modern and complete systems of electric tramways in the world.

DUBLIN TRAMWAYS

Only second in interest to this first Bristol line, and of more importance as regards length of line and the special and important mechanical and electric equipment which the greater length of line demanded, is the Dublin, Kingston & Dalkey Electric Tramway, 8 miles in length. This line was inaugurated as an electric tramway by the Lord Mayor of Dublin on May 16, 1896.

In point of construction of the permanent way all the experience of Bristol was adopted, and, where possible, improved upon, and as the line at some places in Kingstown and Dalkey lay along curved and sometimes rather narrow streets, and considerable differences in levels and contours of roadways had to be adjusted, the roadbed formed a problem which it took much care and contrivance to solve. But in the general detail, so far as the line below and above was concerned, the Dublin line merely repeated and accentuated the experience in Bristol.

It was different as regards the power house and the distribution of the current. The stringency of the Board of Trade regulations at once demanded that on a line of such extent special provision must be made, because, despite the greatest care in insulation and in the proper bonding of the rails as a return for the current, it was almost impossible to preserve so small a drop in voltage as the Board of Trade regulations allowed. In place of distributing the current for the whole 8 miles from one center, two substations were established—at Blackrock and Dalkey—so that the work of distribution was made from three points. Had the service been from the main power house only, the current would have been always in one direction, and the accumulation of minor (and unpreventable) leakages would no doubt have rendered the preservation of a maximum drop of 7 volts difficult, if not impossible. The means taken to counteract this difficulty I shall now proceed to describe.

In the initial plant the power house contained four Willans & Robinson engines, the flywheels carrying 18-in. belts, by which the electric generators were driven. Two of these generators are direct current, each capable of giving 100 kw. continuously, or 120 kw. on emergency. These dynamos supply directly the section of line nearest Dublin. The other two engines drive two three-phase alternators, which constitute the special feature of the installation. These alternators are six-pole, of capacity of 150 kw., and are driven with a frequency of 30 periods per second. The general design and construction of these machines were effected by the eminent electric traction expert, H. F. Parshall, who has been my coadjutor in most of the various works in this country, and whose idea of the three-phase distribution had its first extensive illustration here. From the power house at Ball's Bridge, two cables carry the currents generated by those machines to the substations at Blackrock and Dalkey. The current is carried at high tension, averaging 2500 volts, and at the substations it is transformed to the required line current of 500 volts continuous. At Blackrock there are two three-phase synchronous alternate current motors connected direct with two direct current railway generators, capable of working up to 75 kw., and from the latter the portion of line nearest Blackrock is supplied with current of the standard 500 volts. Similar apparatus at Dalkey, somewhat less powerful, takes off the high tension current from the cable and transforms it for the supply of the third section of the line.

Some of the practical advantages of this system are that by its use a much greater number of cars can be operated without breaking the Board of Trade rule; that the three-phase method of distribution requires about three-fourths the weight of copper which would be required by a single-phase alternating current system of the same voltage; that the motor generators may be run from either the 500-volt continuous or the 2500-volt three-phase mains; and that by the use of the synchronous motor the phases of the alternating currents can be so governed that the amount of power delivered to any substation can be regulated as desired.

The convenience and flexibility of the motor generator method of transmitting power is quite apparent when it is borne in mind that the reaction on the field of the synchronous motors can be compensated for by a few turns of wire in series with the armature of the generator to which it is coupled, thus keeping up the counter e.m.f of the motor, and insuring that under no circumstances whatever can the motor be thrown out of synchronism. The combined efficiency of the motor generator set is 85 per cent at full load. Another feature of the station which gave great satisfaction was the operation of the switches on the three-phase circuit. They consist of three switches mechanically operated from a single line through wooden connecting rods about 3½ ft. long. Their efficiency was tested by repeatedly breaking the circuit, and no instance of an arc being maintained is yet recorded.

During the tests which were made on this system the railway generators which are directly coupled to the three-phase motors in the substation were directly short circuited, and also run for some time at 60 per cent overload, but under no circumstances was it found possible to pull the synchronous motor out of step. The switchboard in the Blackrock substation has two panels for the distribution of power from the 500-volt generators. On the three-phase part of the board there are five three-phase switches, one for cutting out each of the cables coming in from Ball's Bridge, one for cutting out the cable that extends on to Dalkey, and one for cutting out each of the synchronous motors.

The three-phase synchronous motors are excited by means of the 500-volt continuous current machine. These three-phase motors are self-starting, but in normal practice the machines are brought to speed by means of the continuous current generator used temporarily as a motor, and driven from the 500-volt trolley line, which receives this starting current from the main power station at Ball's Bridge. This is the modus operandi of starting up one substation when neither of the machines is running. When one of the machines is running the current for starting the other is, of course, obtained from it.

The success of the Dublin Southern was so marked that the Dublin United Tramways Company has been led to convert to electricity the whole of its lines, which amount to some 75 miles of single track. The central power station at Ring's End, now under construction, will have a capacity for operating 600 cars. The coal handling is to be done entirely by automatic machinery. The boilers are of the water tube type, equipped with Vicars' stokers. The engines are of the vertical cross-compound type, with Corliss valve gear, and run at 90 r.p.m. Owing to the favorable location of the new power house it will be found possible to work the whole system by continuous currents. Earth boosters and pairs of test wires are run from the station to various points in the earth return system, so that the voltage drop can be regulated to any desired extent.

MIDDLESBROUGH, STOCKTON AND THORNABY ELECTRIC TRAMWAYS

The power station of this road contains three alternators of the three-phase type, each of 300 kw. capacity, 32-pole 2500 volt, giving a frequency of 25 cycles at 94 r.p.m. The fields are excited from the 500-volt bus bars. To supply light when the machinery is shut down and to start the dynamos in the morning a battery of accumulators has been provided. These are by the Tudor Company, and consist of 260 cells, with a discharge rate of 48 to 70 amps.; the capacity at the lower discharge rate being 240 amp.-hours. For charging these accumulators a boster is connected in series with the 500-volt bus bars. This booster consists of a rotary converter fed from step-down transformers of special design. Each transformer has the primary and secondary separated so as to give the effect of a considerable reactance, this arrangement giving a large range of voltage on the rotary converter to provide for the alteration in the charging volts required by the cells. The rotary converters employed at the generating station and at the substation are of comparatively recent introduction into this country, and have been employed in preference to motor generators on account of the high efficiency which they give and the general ease of their manipulation. They consist essentially of direct current generators, to the armature winding of which connections are made at suitable points to a set of three collector rings on the end of the shaft opposite that occupied by the commutator. The three-phase current is led into these collector rings and the machine is run at the correct speed for 25 cycles. The same winding thus serves both for the alternating current led into the machine and for the direct current taken out.

The system of distribution of electrical power is further specially designed to give the maximum power at any point of the system on the most economical basis. A 500-volt continuous current direct from the rotary conyerters in the central power house feeds the trolley lines on either side, while the Middlesbrough and Linthorpe sections of the lines are fed by a current transmitted at 2500 volts from the central station to the substation at Newport, and there transformed down so that power is delivered from this subcenter direct into the line at 500 volts.

The considerations leading to the adoption of this method of distribution had reference not only to the position of the main generating station and the properties otherwise available as car sheds, machine shops, etc., but to the length of the line, and the

regulations of the Board of Trade as to the earth return. The experience in Dublin was repeated here. With the number of motor cars to be operated on the lines in the borough of Middlesbrough, had the current been supplied at 500 volts direct from Stockton, the drop in the earth return between the termini at Linthorpe and Ormesby Road and the Stockton main station might have exceeded the prescribed limit, and in order to secure compliance with the Board of Trade regulations a substation was established at the Newport depot for the distribution of the current.

The feeder cable which transmits the three-phase current at 2500 volts from the central power house to the substation consists of two three-core cables, in each of which are three conductors of copper suitably insulated, each conductor having an area of 50 sq. mm. or .0775 sq. in. With this small section it is possible to transmit 300 kw with a loss of less than 5 per cent. At the substation this current is reduced by step-down transformers of 80 kw. capacity to 320 volts, and this current is then passed into the alternating current side of a rotary converter, from which a direct current of 500 volts is drawn to feed the portion of the line supplied from the substation. The two four-pole rotary converters of 200 kw. capacity running at 750 r.p.m. in the main power station feed direct into the portion of the lines supplied.

A novel feature of the main station equipment is the combination of static and rotary transformers for charging the batteries, specially designed for this installation. The charging current is passed through the rotary, and raised from the line voltage 500 volts to a maximum of 650 volts for charging. There being no direct current primary generators in the station, it became a problem how to charge the batteries for supplying the excitation to the three-phase generators. This was solved in the following manner: A rotary converter was designed to supply the difference between the line voltage and the variable voltage required for charging; combined with this is a static transformer having a ratio of transformation of 330 to 80 volts on a non-inductive load. The transformer was designed with a large amount of leakage between the primary and secondary, the leakage being adjusted so that by changing the phase of the armature current by variation of the field current of the booster, the transformer ratio is varied, and consequently the voltage on the collector rings. In this way it is possible to vary the voltage on the continuous side of the rotary from 40 volts to 150 volts. The charging current is 60 amps. The armature of the rotary is designed to carry 60 amps. continuously.

In common with the Bristol and Dublin lines, two wires are extended above the tracks from end to end of the system, and convey current to the car motors by means of trolley poles fitted upon each car. The wires are of hard-drawn copper, .364 in. in diameter, and are divided electrically in half-mile sections by sectional insulators. There are overhead points and crossings at the ends of the lines and at the branches leading into the main and substations, and on the lines as well as in the substations the cars are moved and handled entirely by the trolley.

The section pillars are placed at each half-mile section on the road. They are about 4 ft. in height, and are placed on the curb lines, so that they are accessible from either side. The "Columbia 0000 rail bond" is used.

The Middlesbrough & Stockton track has a gage of 3 ft. 6 ins., and it will be obvious at once that the problem of constructing roomy and commodious vehicles is much more difficult on a gage of 42 ins. than (as in Ireland) on a gage of 63 ins. The cars carry sixty passengers, thirty inside and thirty outside, and this is seven more than were carried by the first electric car put on the Dublin-Dalkey line, and sixteen or seventeen more than were carried on the first electric cars at Bristol. We have thus shown that by judicious planning even the narrow gage line can give on each car as much public accommodation as where the lines are wider. The use of the larger type of bogie-truck motor cars, which I especially designed for this line, obviates the use of trailer cars, which are opposed to the most advanced principle of street railway practice—namely, to employ as units of service self-contained cars run at short intervals.

THE LONDON UNITED TRAMWAYS

The main work at hand in this kingdom at present in the extension of electric traction is that in the western suburbs of London, on lines owned and projected by the London United Tramways, occupying the district extending from Hammersmith to Hounslow and Hampton Wick on the southern boundary, and from the Central London Electric Railway terminus at Shepherd's Bush to Hanwell and Uxbridge on the north, with junction lines uniting these tramways into one vast system, amounting, if all that has been proposed should be carried out, to over 39 miles of road line, and practically to 75 miles of track. As regards actual accomplishment, the system already extends (working or under construction) to about 27 miles of route, and the balance is, to the extent of 13½ miles, actually under promotion, while a section of main road of about 2½ miles through the suburb of Ealing will come before Parliament next session.

On 1 mile of this the London County Council insists that we shall experiment with some method of underground electric conduit.

The London United original system, which is under process of reconstruction as described, is unique in its electrical arrangements. On account of the requirements of the committee of the Royal Society appointed to protect Kew Observatory, the company has been debarred from using the rails as an earth return, consequently the overhead wires are on the double insulated trolley system. Such a system, when connected up on the two-wire principle, requires, practically, twice as much copper in the conductors as a trolley system installed on the usual lines. To overcome this difficulty, and likewise to increase efficiency, the overhead trolley wires are connected up on the three-wire system, the two center wires forming the neutral, and the outside wires the positive and negative side. The neutral wire is grounded at the station, and at the central station only.

In the present session we are promoting extensions from points on the Hounslow line, to bring into direct tramway relation with London the favorite residential suburbs of Twickenham, Teddington and Hampton Court. Should our application to the Light Railway Commissioners prove successful, we shall, when completed, have a comprehensive system of 40 route miles of electric lines, with 250 motor cars in operation.

The power station will be in High Road, Chiswick. It will be a one-story building of brick and freestone, 154 ft long and 106 ft. wide, divided into an engine and boiler room. The boiler room will be 45 ft. wide, and consist of a steel frame structure in order to carry the heavy weights due to the coal storage bunkers (holding 500 tons), economizers, flue and water tanks, which will be located on a floor above the boilers. This steel structure will extend to the roof, and thus make the boiler room practically independent from the engine room.

The coal supply will be delivered from the ground level outside the building to the coal bunkers above the boilers by a noiseless gravity-bucket type of conveyor, capable of handling 40 tons per hour. This conveyor will also remove the ashes, dumping them into a special ash bin, from which they can be readily removed. An additional coal store of 2000 tons' capacity will be provided north of the boiler room. It is intended to deliver coal to the stores direct from the North & South-Western Junction Railway's depot, about 700 ft. distant from the boiler room, by means of a gravity-bucket conveyor. Alongside the coal siding, and entirely below the surface, will be placed a receiving hopper with the necessary apparatus for the delivery of coal to the conveyor, thus enabling the coal to be handled automatically direct from the railway trucks and to and from the company's coal stores and to the stoker hoppers.

The boiler room equipment will consist of eight horizontal water-tube boilers, each having a capacity of evaporating 8250 lbs. of water per hour at a steam pressure of 160 lbs. Each boiler will be fed by a mechanical stoker of the "Coking" type, the coal being delivered to the stokers by weighing hoppers from the coal bunkers above the boilers, thus securing a record of the exact amount of fuel consumed by each boiler.

The economizer, located on the floor above the boiler room, will consist of 360 tubes in thirty-six sections, provided with motor-driven scraping and cleaning arrangements. Here also will be two water tanks of 6000 gals each.

The smokestack is to be 10 ft. clear inside diameter, and 200 ft. in height above the foundations. This stack will be built of steel plates in rings, lap-jointed and riveted, tapering upwards, and finished with an ornamental cap. It will be entirely self-supporting and lined inside with firebrick.

The engine room will contain one 25-ton overhead traveling crane traversing the length of the room. There will be three vertical cross-compound condensing 750-h.p. engines, with cylinders 22 ins. and 44 ins. x 42 ins. stroke, three of them running at 90 r.p.m., and each of these having two 500-kw. electric generators; the fourth engine, running at 94 r.p.m., will be direct coupled to a 500-kw. three-phase 5000-volt generator, with a frequency of 25 cycles per second.

The lighting sets will consist of two two-crank tandem compound engines, each directly coupled to a 75-kw. 500-volt generator, and running at 400 r.p.m.

The condensing apparatus will consist of surface condensers of the Admiralty type, each containing 3200 sq. ft. of cooling surface, and located on the engine room floor. Each condenser will be supplied with a vertical cross-compound combined air and circulating pump, with steam cylinders 8 ins. and 15 ins., and air and water cylinders 20 ins., double acting, all 15-in. stroke.

Two cooling towers will be erected for cooling the water for condensation, these being of the twin type, arranged in two sections, having capacity to care for 4000 h.p., covering a ground space of 40 ft. x 15 ft. and 38 ft. high. The mats composing the cooling surface will be of galvanized iron wire netting, and a proper distributing system for the water over these mats will be provided. There will be two air propellors for each section of tower, operated at 160 r.p.m. by a direct-connected electric motor when giving maximum capacity; two vertical compound duplex boiler feed pumps, each of sufficient capacity, will feed all the boilers. The hot well will consist of a cylinder 48 ins. in diameter and 96 ins. long, the feed water for the hot well being passed through two feed water filters to thoroughly extract all oil before passing to the boilers. An auxiliary feed water heater will be supplied, having 520 sq. ft. of heating surface for heating the feed water before passing it into the economizer, exhaust steam from the boiler feed pumps and other auxiliaries being available for this purpose.

One motor generator set, consisting of one three-phase synchronous motor, having 500 kw. capacity at 5000 volts, and direct connected to two 250-kw. 500-volt generators, will be located in the engine room for converting from direct to alternating current and vice versa, for convenience on light loads and as a spare generating unit.

The switchboard of white marble 2 ins. thick, bolted to angle-iron framing, will contain ten generator panels, two lighting generator panels, one instrument panel, nine feeder panels, and also two three-phase generator panels, and two three-phase feeder panels, and will be supplied with the necessary instruments and switches.

The electrical current will be distributed over the whole of the company's system by lead-covered paper-insulated cables, drawn into cement-lined wrought-iron pipes laid under the footpaths of streets. As many as thirty of these cables radiate from the central power station at Chiswick, over one million feet of these pipes being required.

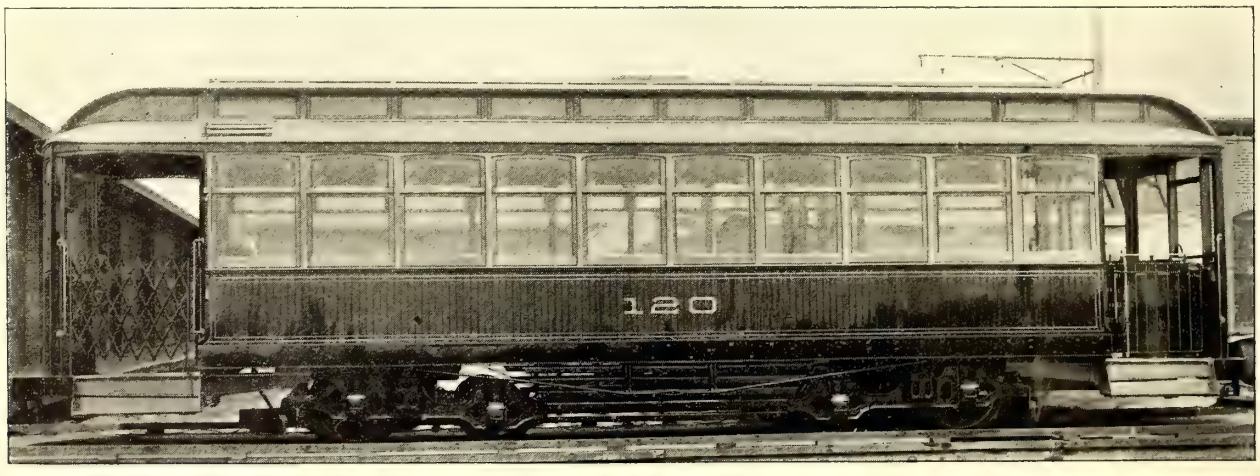
The London United system is almost entirely double track, and over the rails of each track will be located two trolley wires about 21 ft. in height from the ground, the two inside wires being interconnected and forming the neutral. The overhead lines will be divided into half-mile sections, and in order to meet the Board of Trade's requirements, each 1½ miles of the line being supplied by an independent feeder running direct from the power station, the neutral return also being reinforced for each section of 1½ miles by a separate feeder.

A section of the line furthest from the center of the system, about 8 miles in length, will be operated from a substation. This substation will be fed from the central power station through duplicate three-core lead-covered paper-insulated cables, power being transmitted at 5000 volts on the three-phase system. The substation will have a switchboard consisting of two three-phase high tension feeder panels, six transformer panels, four rotary converter panels, four feeder panels, and two instrument panels, the switchboard being similar in design and finish to that in the main generating station. In the substation will be provided seven static transformers (one being an extra), each of 150 kw. capacity at 25 cycles per second, transforming 5000 volts to approximately 350 volts. The cooling air for these transformers will be supplied by an electric motor directly connected to a suitable fan. Four rotary converters will also be supplied, each of 200 kw. capacity, and 6-pole machines running at 500 r.p.m, and delivering current at 550 volts, for supplying sections of the line radiating beyond 6 miles from the central power station at Chiswick.

The substation is designed generally on the lines of that already existing at Stockton, but there is a difference in the electric connections, owing to the rotatory converters feeding into a three-wire system. These machines will be electrically connected, so as to act both as rotary converters and as balancers; that is, in case one side of the three-wire system be overloaded, the rotary converter acting on the opposite side of the system will act as a motor, and thus assist the overloaded machine.

New Cars for Camden

The Camden & Suburban Railway Company, of Camden, N. J., has recently put into service on its interurban line a large number of 40-ft. double-truck cars of the design shown in the accompanying illustration. These cars were built by the St. Louis Car Company, from plans and drawings upon which considerable time had been expended, as the desire was to get a convertible car to answer the purpose of both a summer and winter car in every particular. The length of the body from outside to outside of corner posts is 28 ft., and from outside to outside of vestibules 38 ft. These cars are built on the style of steam coaches, with straight sides, and have ten windows on each side.



The side sills are plated with ⅝-in. x 8-in. steel plates, and the platform knees with ½-in. x 7-in. steel, while the bumpers are faced with ½-in. x 8-in. steel plates. The bottoms of the cars have truss rods extending from the corner of the sills through the inside sill to hold up the platform end of the car, and there is also a center truss rod between trucks underneath the sill. The cars are equipped with the St. Louis Car Company's patent sand boxes, and ratchet wheel brake, and are very handsomely finished throughout with solid bronze trimmings, highly polished.

The cars are furnished at each end with a vestibule 5 ft. long, with three drop sash in the end. The sides of the vestibule are open, and one side is provided with a Wood gate, while the other side is fitted with a large channel iron folding gate. Arrangements are made for one illuminated sign and hangers above the center sash in vestibule.

The interior finish of the cars is of the best quality white cane ash, finished in natural color. The ceiling is of quartered oak, finished in natural color and neatly striped. The seats are of the St. Louis Car Company's spring rattan "walkover" type. There are sixteen seats, accommodating two passengers each, and one stationary seat at each end accommodating three passengers each, making the seating capacity thirty-eight passengers to the car. The sides of the car are so constructed that when the sash are dropped down they are completely out of sight, and are held firmly by guides so they do not rattle. The opening is covered by a cap, which extends the entire length of the window pane. The windows are fitted with the best quality of Pantasote curtains, with the St. Louis Car Company's patent wire cable fixtures. One end of each car is fitted up as a smoking compartment, with sliding doors in the partition, but these doors and partition are so arranged that they can easily be moved by the railway company if so desired.

The roof is of the full ventilator, steam coach style, and is fitted with ornamental glass. The cars are wired for four two-light clusters, and one light at each end for illuminating the sign in the vestibule.

The bodies are mounted on the St. Louis Car Company's steel

DOUBLE TRUCK CAR FOR CAMDEN, N. J.

maximum traction trucks, No. 13. The diameter of the large wheels is 33 ins., the tread 2 ins., and flange ¾ in. The car will be equipped with No. 38 Westinghouse motors.

Report of the Detroit Street Railway Commission

On May 23, 1899, the commission appointed by the Detroit City Council to consider the purchase of the Detroit street railway system rendered a report to the Council, which is given in its entirety below, together with the report of the commission's actuary, Prof. Edward W. Bemis, of the Kansas State Agricultural College. A few words of preliminary explanation are perhaps necessary in order that the full meaning of this report be understood.

On March 24, 1899, the act known as the "McLeod Law," which authorizes the city of Detroit, Mich., to construct, acquire, maintain and operate street railways, was passed by the Legislature of Michigan and approved by Governor Pingree. It provided for the appointment of a street railway commission of three members, to be given authority to construct and acquire the railways for the city and to operate and maintain them. The Common Council of Detroit, in accordance with the act referred to, on April 1, 1899, selected H. S. Pingree, Elliott G. Stevenson and Carl E. Schmidt as members of the Detroit street railway commission.

The negotiations with the representatives of the street railway companies were concluded on May 23, 1899, and the result is given in the following report of the commission to the Common Council of Detroit:

To the Honorable, the Common Council of Detroit:

Gentlemen—We hereby report to you the result to date of the steps taken by the undersigned members of the street railway commission, looking to the acquirement of the street railways of Detroit for the purposes of municipal operation.

Two elements have entered into the question of fixing the value of such properties:

First. The physical property—real estate, power houses, cars, tracks, equipment, etc.

Second. The franchise rights and privileges, controlled and owned by the companies now operating such railways. This element, in short, is made up of the profit the present owners of the railway properties would make above operating expenses, fixed charges, interest upon value of physical property, etc., during the life of existing franchises.

To ascertain the value of the physical property we secured the services of the following experts: Prof. M. E. Cooley, J. D. Hawks, Gilbert Wilkes, George Dingwall, Albert Albrecht and Henry Spitzley, who were given instructions to take all the time necessary to thoroughly examine and ascertain the conditions of all the physical property, to verify the inventories submitted by the present owners, and to appraise such property at its present cash value—that is, what it would cost at this time to reproduce it, making proper deductions for depreciation on account of its use.

The experts named, we believe, have faithfully discharged their duties, and have reported the result of their labors. Their several reports fix the aggregate value of the physical property, after making allowance for depreciation, at $7,808,737.42.

The railway company insisted that this amount was too low by a million dollars. We have carefully investigated the claims made by the company as to the points of difference, and have reached the conclusion that, as to some parts of the property, the appraised value is a minimum value, and as to other parts it is the full value, and that, on the whole, the work of the appraisers is approximately the fair cash value of the property.

But for the purposes of our investigations and the calculations to be made to ascertain the value of the franchise, we have proceeded on the basis of the value being $8,000,000.

We have done this for the reason that in so doing the result in reaching the value of the entire property—physical and franchise—is not materially affected.

To make clear what we desire to express in this regard, it should be borne in mind that the franchise value is the aggregate of profits that would be realized during the lives of the franchises (reduced to present worth), and that to ascertain the profits, operating expenses and interest on the physical property necessary to produce the earnings, are to be deducted from the earnings. If the larger amount, $8,000,000, is taken as the value of the physical property, the amount deducted from the net earnings for interest on value of physical plant is larger, and therefore the franchise value is reduced, so that in reaching the net result, the difference, whether the value of the physical property be taken at $8,000,000 or $7,808,732.42, is comparatively slight.

To ascertain the value of the franchise owned by the railway companies Mr. E. B. Hutchinson, an expert accountant, has made a very complete examination of the books, records, vouchers, etc., of the railway companies, covering a period of four years, the entire period during which the railways have been operated with electricity as motive power. His report shows that the net earnings of the railway properties for the year ending April 1, 1899, were $805,000. While the work of Mr. Hutchinson was entirely satisfactory, we took the precaution to have it, in respect to the question of the gross and net earnings of the companies, verified by Prof. E. W. Bemis, whom we employed as actuary to make the necessary calculations to fix the franchise value of the property.

Prof. Bemis confirmed the result reached by Mr. Hutchinson as to earnings, but as a matter of precaution concluded it was prudent to deduct $55,000 from the net earnings as shown by the books for the past year, to cover possible, if not probable, increase in operating expenses, depreciation, etc.

The report made to us by Prof. Bemis fixes the aggregate value of the franchises owned by the railway companies at $8,478,563.86. His computation is made on the basis of $750,000 net earnings, deducting 4 per cent on $8,000,000, value of physical plant, and allowing for 4 per cent annual increase of traffic and earnings during the lives of the franchises. This franchise value, viz., 8,478,-563.86, added to the value of the physical plant, viz., $8,000,000, makes the total value of the street railway property and franchise rights $16,478,563.86. We submit herewith Prof. Bemis' report, showing the method adopted by him in reaching the conclusion he did, as well as observations made by him on the general subject under consideration.

In the matter of the franchise value, as in nearly every matter considered, we have had more or less controversy with the railway companies' representatives, and it is perhaps but fair that we give to the public their contention in relation to this subject, as contained in a communication submitted by them on being advised as to the result reached by Prof. Bemis, and the basis upon which he reached it. They contended as follows:

"1. That the method followed by the actuary of valuing the franchises is very unfair to us, because it allows only a 4 per cent annual increase in net earnings, while the net earnings of the company for the past four years have increased at a very much higher rate than the gross earnings. The gross earnings have increased at the average rate of 6.3 per cent per year, as shown by the report of your actuary. If a period of five years be taken, the increase in gross earnings is shown to have been nearly 8 per cent, and in view of the very much larger increase shown in the last few months, and the fact that the last four years have not been typical years of growth, the percentage of increase adopted by the actuary is entirely too small.

"2. That Prof. Bemis arbitrarily reduces the net earnings of over $805,000, as shown by your accountant, to $750,000, and as a result of this deduction of $55,000 a year, with its proportionate increase, the franchises are valued by him at over $1,000,000 less than they should be valued by the method of appraisal adopted by you."

In relation to the contention of the railway company above set forth, we were of the opinion that while the estimate as to increase of traffic and earnings upon which our calculations were based was lower than that shown by the experience of the railway company company here, as well as in other cities, during the four years referred to, yet we ought to have some margin in this record to offset possible reduction of receipts upon inaugurating three-cent fares.

In reference to their complaint as to the reduction of amount of net earnings to $750,000 from $805,000, we were of the opinion that it was justified as a matter of prudence and caution, and are therefore of the opinion that the amount fixed by Prof. Bemis represents the full value of the property.

After Prof. Bemis had given us the result of his investigations and calculations the railway companies' representatives submitted their first definite offer as to price, fixing their price for all the railway properties and rights at $17,500,000—the property being that a new security franchise covering all the lines be granted to a new company, which new company would execute bonds secured by mortgage on all the property of the companies and the security franchise for $17,500,000, and then the city would acquire such property, subject to the payment of such mortgage indebtedness.

We have strenuously endeavored to obtain concessions in the matter of price, and have succeeded to this extent only: The company offers to turn over to the commission, to be used for the purpose of making extensions, payment of interest, or carrying out the sinking fund provisions of the mortgage referred to, $400,000 of bonds, and one of the parties interested has offered to turn over for the same purpose an additional $300,000 of bonds, which would provide $700,000 as a safety fund, and practically reduce the purchase price to $16,800,000.

We feel warranted in saying that no better price can be secured on the terms indicated, which are substantially the only terms upon which we can negotiate.

We have had frequent conferences with representatives of the railway company with reference to the terms of the proposed security franchise, and have disagreed upon several important features.

We have contended for a thirty-year limit, while the company's representatives have insisted that under such a limit the sinking fund payments would of necessity be so large and unusual as to materially affect the saleability of the bonds. It is apparent that it would be of decided advantage to the city to distribute the payment of the mortgage indebtedness over a period approximating fifty years, so that the city might inaugurate three-cent fares, and pay such indebtedness out of the surplus earnings, after providing for reasonable extensions of track, increased equipment, cars, etc., to accommodate increased traffic, resulting from low fares. The contemplated arrangement, however, would permit of the payment of the whole or any part of the indebtedness at any time during the fifty years.

However, it was and is our view that without increasing the payments referred to, the security would be ample, even though but one-half of the bonded indebtedness should be provided for at the end of a thirty-year franchise, for the physical property—now worth $8,000,000—with necessary extensions, increased equipment, etc., would be ample security for the payment of what should remain unpaid at that date. But we have been unable to obtain the assent of the sellers to this view, or to any modification as to the length of the franchise, other than this: The security franchise to be for the term of thirty years, with the provision that at the end of that time if provisions shall not then be made for the payment of the balance of the mortgage indebtedness and the mortgage discharged, the franchise shall be extended until such indebtedness shall be paid, not exceeding eighteen years, the limit of time for paying it under the sinking fund provisions referred to.

So that at the end of thirty years, or for that matter at any time before that, by providing for the discharge of the mortgage indebtedness, the security franchise and all rights under it would terminate.

We have contended that the new security franchise should not disturb the provisions of the Detroit Railway franchise, which for twenty-six years secures to the people accommodated by it fares at eight tickets for 25 cents during the day. The representatives of the companies have contended for a franchise uniform in its provisions and embracing all the lines.

The company has finally receded from its position in this regard, and assents to the proposition that the provisions of the Detroit Railway franchise shall continue until the expiration of the same—twenty-six years hence.

We have contended for extension of hours for workingmen's tickets and transfer privileges, reduction of fares to school children, etc. The companies' representatives have stood for an extension of existing franchises, but have finally acceded to the following:

Six tickets for 25 cents, good at any time.

Eight tickets for 25 cents, 5:30 A. M. to 7:30 A. M.

Eight tickets for 25 cents, 5:00 P. M. to 6:30 P. M.

Ten tickets for 25 cents, 7:30 A. M. to 5:00 P. M., for pupils attending school; all with universal transfers.

To intelligently determine as to the advisability of acquiring the street railway properties upon the terms outlined, the controlling consideration, in our judgment, should be whether such a plan as is outlined can be carried out successfully and insure to the people of the city of Detroit three-cent fares immediately and permanently. With that end in view we have conducted our investigations, and have also given consideration to the consequences that might result from failure. We have, to the best of our ability, weighed all arguments for and against the plan, and have reached the conclusion that under the plan outlined, three-cent fares with universal transfers can be immediately and permanently secured to the people of Detroit.

In reaching this conclusion we have not only had the benefit of the judgment of people who are more competent to judge wisely in reference to the question than we are, but have also had the actual experience of the Detroit Citizens' Railway Company for seven months in 1896, during which time it operated its lines on the basis of eight tickets for a quarter. We found, according to the investigations made, that the gross earnings of the company were during that period greater on the basis of eight tickets for a quarter than they were during the same period the following year at six tickets for a quarter. The expense attending the handling of the increased traffic, however, exceeded the expense during the same period the following year, and the net earnings were slightly less than under the operation at six tickets for 25 cents.

The report of Prof. Bemis submitted herewith, as stated, outlines the basis upon which he reaches his estimate of the franchise values of the railway properties. The following shows the basis upon which the mortgage indebtedness referred to will be discharged through the sinking fund provisions of the mortgage:

$50,000 on the 1st of September, 1900, 1901, 1902 and 1903.

$75,000 on the 1st of September, 1904, 1905, 1906 and 1907.

$125,000 on the 1st of September, 1908, 1909, 1910 and 1911.

$180,000 on the 1st of September, 1912, 1913, 1914, 1915, 1916, 1917, 1918, 1919, 1920 and 1921.

$200,000 on the 1st of September, 1922, 1923, 1924, 1925, 1926, 1927, 1928, 1929, 1930, 1931, 1932, 1933, 1934, 1935, 1936, 1937, 1938, 1939, 1940, 1941, 1942, 1943, 1944, 1945, 1946, and $37,800 September 1, 1947.

Those payments, together with the interest on the bonds, purchased for the sinking fund, by their use, will retire all of the $17,500,000 of bonds September 1, 1947.

It will be noted by the report of Prof. Bemis that he recognizes the possibility that for the first five years of operation on three-cent fares the net earnings of the properties may not exceed the net earnings of the past year at the higher rates of fare. Having this in mind, the sinking fund provisions have been so regulated that there will not be any danger, even if no increase in earnings is realized for five years, of not being able to meet the interest and pay the money required for the sinking fund.

To illustrate, the interest upon $16,800,000 would be $672,000; the sinking fund provision for the first four years is $50,000 per year, making a total of $722,000 annually, a sum $83,000 below the net earnings as shown for the past year, and $28,000 below such net earnings after making the deductions referred to for increased operating expenses, etc.

In fact, it will be seen from the figures submitted, that if no increase in the earnings over the last year was attained for twelve years, the interest upon the entire bonded indebtedness, and in addition the payments for the sinking fund, would be provided for safely, and the largest sum that will be required at any time, commencing approximately twenty-five years hence, would represent but $122,000 more than the net earnings of last year, as reduced by Prof. Bemis—an amount which would be largely made up by one item—of withdrawing deadhead tickets and having every one pay his own fare on the reduced basis.

That there are many items representing large amounts that can be saved under municipal operation, there can be no question—so many that we feel no hesitation in expressing our confidence that the security franchise, if granted, would never become more than a security franchise.

But, as stated, we have given consideration to the possibility of our judgment proving erroneous, and to the result that would attend the failure of municipal ownership and operation, and as we see it, the result would be as follows:

In any event, the city would control the situation, and the alternative would not be presented of having to pay the bonded indebtedness or permitting the security franchise to become an active one.

And the city could, in the event of being dissatisfied with the result of municipal ownership, lease the railway properties on the best terms attainable, using the rental, so far as necessary, to keep up the payments to which reference is made. Or, if any corporation or other organization would undertake the operation of the railways of Detroit on terms more favorable than the terms provided for in the security franchise, the city having control of the situation, could then make any bargain it saw fit, and either at once discharge the mortgage indebtedness by payment, or meet it as it matured under the provisions of the mortgage. This is made possible by a provision of the proposed mortgage that the mortgage indebtedness can be discharged at any time upon sixty days' notice.

If no more favorable terms could be obtained, the worst situation the city could be placed in would be that the security franchise would become an active one on the terms specified above. Such a situation would be much more favorable than the present, for the following reasons:

While the owners of the present railway properties give to the public six tickets for a quarter, they are not obliged to do so, but could at any time exact straight five-cent fares on all lines except the Detroit Railway lines. Under the security ordinance, if it shall become an active one, the railway companies would be required to sell six tickets for 25 cents, good at any time.

Under existing conditions, the eight tickets for 25 cents on the Citizens' line (workingmen's tickets) are good only between 5:30 and 7 A. M., and 5:15 to 6:15 P. M. No transfers are provided for on workingmen's tickets. Under the proposed security franchise workingmen's tickets at eight for 25 cents would be good from 5:30 to 7:30 A. M., and from 5 to 6:30 P. M., and transfers would be issued on all lines having same rates of fare.

The present franchises do not compel the railway companies to

grant transfers, although they do so at present on certain lines. Under the proposed security franchise the right of universal transfer on all lines having same rates of fare is secured.

Under existing conditions no concessions are made to pupils attending public or other schools of the city. Under the proposed security franchise for the use of pupils attending public and other schools in the city tickets good from 7:30 A. M. to 5 P. M. will be sold at the rate of ten for 25 cents.

On the whole, we think it will be recognized that even if the security franchise should become an active one, very substantial advantages are secured to the people of the city under its provisions. But, as stated, we feel confident that the security franchise would never become an active one, and that if the plan suggested can be carried out with the co-operation of your honorable body and the public, the people of the city of Detroit would immediately and permanently have the benefit of rates of fare as low as three cents, with universal transfers.

Before closing this report we desire to state that for several weeks past we have endeavored faithfully and earnestly to secure a reduction of the price. We have been unsuccessful, owing, we believe, in part to the fact that by the arrangement, as the owners view it, we would be securing the benefit of the use of this property without paying anything whatever upon its purchase price, or ever being required to pay anything except out of the earnings of that which is turned over by the present owners.

We would not look with favor upon the city becoming obligated to provide for the purchase price of the property, fearing that an increase for such purposes in the obligations of the city might hazard its present excellent credit. The proposition that is here presented is one that does not call for the payment of a single dollar by the city, or for the city in any way, directly or indirectly, becoming obligated, in any manner or at any time, for the payment of any part of the purchase price of the properties, nor is it rendered possible that in carrying out the plan the taxes of any taxpayer can be increased in providing for the purchase price.

The easy conditions under which the city can undertake the operation of the street railways undoubtedly enhance the cost, but the result, in our opinion, even at the enhanced cost, is simply to defer the time when rates of fare upon the street railways of Detroit can be reduced below three cents.

On the other hand, it should be understood that if the city should not acquire the railways under the proposed plan, the people of Detroit will pay to the owners during the life of the present franchises, in fares, more than the amount of the indebtedness which it is proposed to place on the property.

A study of the statement of payments required for the sinking fund will, we think, satisfy any one who will carefully consider the situation, that there can be no question as to the earnings providing for the payment of the property, even at the price demanded, and at the same time give the people of Detroit the low fares desired. The reduction of fares to three cents alone will represent a saving to the people of Detroit of $500,000 to $800,000 a year, which, within the life of existing franchises of the company, more than represents the franchise value of the properties of the railway companies.

This we report as the best price, terms, etc., we have been able to secure—the best, we believe, that can be secured. The question as to whether they are such as to warrant their acceptance is one which we feel ought to be settled by the electors of this municipality. It is a responsibility that the undersigned are not willing to assume without the sanction of the electors of the municipality, and we therefore report the situation to you, with the recommendation that, at a proper time, the question be submitted to the people for their decision. But we cannot recommend that any steps looking to the granting of a security franchise be taken under existing conditions, in view of the legal questions raised as to the power of the municipality to enter upon municipal ownership and operation of the railways.

If the security franchise referred to should be granted, and bonds secured by mortgage, including such franchise, were issued and sold to innocent purchasers, the franchise might—probably would—be held valid, even though the court might decide that the city could not, by reason of the constitutional objections raised, avail itself of the advantages we have been endeavoring to secure.

We therefore thought it prudent to co-operate in having the legal questions involved definitely determined, and regret that we feel it necessary to recommend that the matter of submitting the question as to whether the people desire the street railways of Detroit purchased upon the best terms we have been able to secure and operated on the lines indicated, be deferred until a decision shall be reached in the case now under consideration by the Supreme Court.

It does not follow, even though the decision of the Supreme Court should be against the constitutionality of the law under which we are now proceeding that the people of Detroit will, of necessity, be deprived of the advantages we have indicated they would secure under municipal ownership and operation of the street railways.

We have contemplated the contingency suggested, and have worked out a plan which, if acceptable to the owners of the railways, and should be approved by your honorable body and the electors of the city, would enable the people of Detroit, even in advance of the decision of the Supreme Court if desired, to avail themselves of such advantages under private ownership, surrounded by such safeguards as will protect the people in their enjoyment until the power shall be secured to enter upon municipal ownership and operation, if such power does not now exist.

H. S. PINGREE,
ELLIOTT G. STEVENSON,
CARL E. SCHMIDT,
Members Detroit Street Railway Commission.

RALPH STONE,
Secretary of Commission.

May 23, 1899.

REPORT OF EDWARD W. BEMIS, ACTUARY.

April 30, 1899.

To the Detroit Street Railway Commission:

Dear Sirs—I herewith submit as full a report of my investigation of the street railway properties as the time at hand allows, reserving for four or five days the presentation of such additional information within my possession as the needs of the commission may require:

I.—THE VALUE OF THE PHYSICAL PLANT

The appraisal of the structural value of all the street railway properties of Detroit, as given by your experts, is as follows:

Track, 175.95 miles, appraised by J. D. Hawks..		$4,350,183.42
Overhead construction, including feeders, ground wires, etc., appraised by Gilbert Wilkes		760,939.00
Citizens' power house	$440,894.04	
Detroit power house	366,249.32	
Citizens' repair shop	8,003.49	
Total power plant	$815,146,85	
Tools and supplies	75,990,59	
Rolling stock	1,102,212.39	
Total power plant, rolling stock, tools and supplies, appraised by Appraiser M. E. Cooley..		1,993,349.83
Car houses, land incident thereto and other land and buildings, appraised by George Dingwall, Henry Spitzley and Albert Albrecht...		523,248.30
Certain other buildings, fixtures and furniture, appraised by Messrs. Spitzley and Albrecht..		179,016.87
		$7,806,737.42

The average cost per mile, if based on the mileage report by the company of 177 miles of single track in the streets, is $44,106. The cost is much greater in Detroit than in most cities, because of the unusually fine roadbed, laid upon expensive concrete foundation, with steel ties.

Mr. Hawks allowed inspection charges of 2 per cent, engineering charges of 5 per cent, incidentals 10 per cent, and interest on the necessary investment during the course of construction at 5 per cent, thereby raising his portion of the appraisal to $24,150 per mile of a single track, or 22 per cent above the mere cost of material and labor. Such allowances, however, are common, and indeed necessary in such construction. It is also customary for street and steam railroad companies to give a contractor's profit of 10 to 15 per cent on the actual cost of construction. Companies even then will save money rather than by doing their own building. Mr. Hawks balances this contractor's profit over against depreciation, and makes no direct allowance for either in the above figures.

Mr. Wilkes does not explain in his appraisal whether he allows for engineering charges, incidentals, etc., but deducts an 8 per cent depreciation from his total of $827,108, in order to reach the figure given above, of $760,939.

Prof. Cooley has allowed 10 per cent as contractor's profit on the cost of reproduction of the Detroit Citizens' power house, and also 5 per cent a year for four years, or 20 per cent depreciation on the machinery there, including generators, 2½ per cent a year for four years, or 10 per cent, on the cost of electrical equipment, excluding generators, 2½ per cent a year for four years, or 10 per cent, on the cost of the building, or a total depreciation of 14 per cent. A similar treatment was applied to the power house of the Detroit Electric Railway, although for a shorter time, three years in the case of the machinery and generators, since they have

been more recently constructed. As Prof. Cooley states, "In obtaining the present value of the rolling stock and equipment parts, the condition of each separate article has been noted and a record made. The equipment parts were valued on the spot, but the valuation of the rolling stock was made after taking into consideration the amount of money spent per annum for repairs. The average percentage of depreciation for all rolling stock amounted to 16.8 per cent, or, in other words, the present value is 83.2 per cent of the cost of reproduction to-day."

The street railway officials would like to add $66,000 to Mr. Wilke's figures and $90,000 to Prof. Cooley's, on the theory that there is no present depreciation in the efficiency at least of the rolling stock; but there is a form of depreciation undoubtedly due to the progress of the art, the growth of invention, developing better types of cars, and ultimately forcing a company to discard cars that are as strong as when constructed. The company would also like to add $80,000 to Mr. Dingwall's appraisal, and $20,000 to that of Messrs. Spitzley and Albrecht, or a total of $256,000. Even admitting this claim, the grand total would only be raised to $8,062,737. In view, however, of the fact that there is that form of depreciation just spoken of above from the progress of the art; in view, further, of the exceptionally high prices of material to-day, although the same may continue for quite a while, and for other reasons developed in my talk with the appraisers, I am not disposed to concede any large portion of the $256,000. It is fair, however, to concede that several of the appraisers did not take into account, as indeed they were not asked to do, any interest during construction on the necessary investment, although it was done in other cases. It may fairly, therefore, be conceded that it would cost $8,000,000 to duplicate the present plant to-day, without making any allowance for any loss of profits during construction. In valuing the property in the further computations of this report, I shall, therefore, assume $8,000,000 as the fair cost of duplication. It would make no material difference, however, in the final conclusion, whether it be taken as a little higher or a little lower, because what is added to or taken away from my allowance of interest charge on the structural value of the plant would affect to nearly as great an extent in an opposite direction the allowances for franchise earnings.

II.—THE FRANCHISE OR MONOPOLY VALUE

Of the $8,000,000 total valuation of the tangible assets of the Detroit railways the following has been apportioned by the various appraisers as the valuation of the Detroit Electric Railway:

Track	$1,374,256.15
Overhead construction	255,327.00
Power houses	366,249.32
Other real estate	69,457.37
Rolling stock	201,705.00
Tools and supplies	7,599.06
Total	$2,274,593.90

This total of $2,274,593.90 is $41,659.22 per mile. The appraisers valued the property of the Citizens' Company at $5,532,143.22, or $45,197.24 for each of the 122.4 miles of track that the Citizens' Company seems to have, although Mr. Hawks allowed them a mile less. Reckoning 4 per cent as a fair interest on the structural value of the plant, or $90,983.76 payable yearly, the problem before us is to determine the remaining earnings of the plant during the next twenty-six years of the life of the franchise. The process taken has been the following: The total net income of all the city plants was $805,883.62 during the year ending April 1, 1899. Although the plant has been kept up out of operating expenses in such a state of physical efficiency as almost to justify the claim of the officials, that the plant is as efficient now and has as long a life before it, so far as wear and tear is concerned, as when it was constructed; nevertheless there is, as has already been stated, a depreciation because of the progress of invention, change in the taste of the people for style of cars, etc., which must be allowed for. The vice-president of the road, Mr. Hutchins, estimates that from $60,000 to $75,000 a year will have to be spent for the next ten years in enabling the plant to take care of increased traffic on the present miles of track, and it seems fair to consider $55,000 at least as nearly balancing the depreciation just mentioned, leaving the actual net earnings $750,000, or 93.03 per cent of the $805,883.62. Applying this same percentage to the net earnings of the Detroit Electric Railway last year of $135,996.79, there remains a true net profit of $126,558.64.

Further, the gross earnings of all the Deetroit railways have increased in the last four years at the rate of 6.3 per cent yearly, and the net earnings still faster. This is a lower rate than during the same time in Boston (rate, 8 per cent), Worcester (11 per cent), Springfield (12 per cent), and Lowell (10 per cent), Massachusetts, where sworn reeturns are made to the State. The present year, January to December, 1899, gives indications of yielding from 10 per cent to 12 per cent more than during 1898, if we may judge from the receipts since January 1. It has, therefore, seemed a conservative estimate to assume a future rate of growth of 4 per cent yearly. The competition of the bicycle is not likely to be any keener in the future than in the past, while the growth of population is on the outskirts, at greater and greater distances from places of work. To be sure, there are possibilities of invention, like that of the automobile, but when it is borne in mind that the total expense for motive power to-day in Detroit is less than 8 cents per car mile, and less than one-fifth cent per passenger, or 10 per cent of the total expenses, it will be seen that the possibilities for further economy in motive power are not great.

Returning again to the Detroit Electric Railway, let us assume its corrected net earnings of $126,558.61 increase during next year 4 per cent, or up to $131,620.95. Deducting from this the $90,983.76, as above found for interest on physical plant, there remains a monopoly, or franchise, revenue of $40,637.20, which would have a present worth, discounted at 4 per cent, of $39,052.34. Assuming for the second year that the above $131,620.95 increases at 4 per cent, and there would be at the end of the second year a net revenue in hand of $136,885.78. Deducting again the $90,983.76, we have $45,902.02 as the monopoly earnings during the second year. This has a present value on the same basis as before of 4 per cent of $42,413.47. Continuing this process, we have the following result:

Present worth of monopoly earnings of the Detroit Electric Railway:

First year	$39,052.34
Second year	42,413.47
Third year	45,729.93
Fourth year	48,739.41
Fifth year	51,844.17
Sixth year	54,631.08
Seventh year	57,349.15
Eighth year	60,020.98
Ninth year	62,582.38
Tenth year	65,038.95
Eleventh year	67,397.03
Twelfth year	69,663.83
Thirteenth year	71,847.44
Fourteenth year	73,956.92
Fifteenth year	76,002.40
Sixteenth year	77,995.11
Seventeenth year	79,791.99
Eighteenth year	81,542.64
Nineteenth year	83,261.08
Twentieth year	84,962.78
Twenty-first year	86,467.38
Twenty-second year	87,967.96
Twenty-third year	89,483.68
Twenty-fourth year	91,035.60
Twenty-fifth year	92,400.36
Twenty-sixth year	93,562.68
Total	$1,834.736.74

The present worth then of the probable monopoly earnings of the Detroit Electric Railway is $1,834,736.74. To this should be added the value of the physical plant as above determined, $2,274,594, or a total of $4,109,330.74.

Next, this method may be applied to the remaining railways of the city, which I classify under the general name of the Detroit Citizens' Railway. Since we assumed $126,558.61 as the present total net earnings of the Detroit Electric Railway, the remainder of the $750,000 above computed as the total revenue of all the lines in the city, or $623,441.39 is the present net earnings of the Detroit Citizens' system. Also assuming, as has been done above, that $8,000,000 is a fair value of the physical property, 4 per cent as interest on this is $320,000. Subtracting from this the interest, $90,983.76, allowed on the Detroit Electric Railway, and there remains as interest on the physical plant of the Citizens' lines $229,016.24. Following the same method as with the Detroit Electric Railway, we may assume the above $623,441.39 as increased 4 per cent yearly by increase of traffic. The total net earnings then during the first year would be $648,379.04. If from this we take the interest, $229,016.24, just found, there remains a monopoly earning of $419,362.80, which has a present value of $403,007.65. We then increase the $648,379.04 by 4 per cent for the second year's net earnings, and again deduct the interest charge of $229,016.24. Continuing this process for the ten years and eight months in which the entire Citizens' system has an uninterrupted franchise, and we have the following result:

Present worth of the monopoly earnings for ten years and eight

of the Citizens' Railway (including all except the Detroit Electric Railway):

First year	$403,007.65
Second year	411,455.21
Third year	420,320.76
Fourth year	427,274.97
Fifth year	435,774.80
Sixth year	442,270.42
Seventh year	448,865.05
Eighth year	455,670.60
Ninth year	462,151.31
Tenth year	468,334.75
Eight months of eleventh year	316,411.75
Total	$4,691,537.27

The total monopoly value of the Citizens' Railway for the next ten years and eight months may be assumed, therefore, as $4,691,537.27, to which may be added $5,274,594, as the value of the physical plant, making a total of $9,966,131.27. After ten years and eight months the eastern end of the Fort Wayne & Belle Isle Railway, which is that portion east of Clark Street, continues for seven months. That portion of the road had net earnings last year of $44,859.60, or 6.7 per cent of $623,441.39, assumed as the real net earnings of the whole Citizens' system. It should, therefore, be charged with 6.7 per cent of the interest charge of $229,016.24, or $15,344.09. The net earnings of the entire system the tenth year, on a 4 per cent increase, would be $922,845.51, and 6.7 per cent of this, or $61,830.65, may be considered as that portion of the total earnings of the Citizens' system that may legitimately be assumed as connected with this branch of the Fort Wayne system ten years hence. This would increase in seven months to $63,273.36. If from this be taken $15,344.09, as above described, there would remain a net earning of $47,929.28, but such a value eleven years hence is equivalent to $39,818.53 to-day. This may, therefore, be assumed as the value of that portion of the Fort Wayne franchise. The other portion of the Fort Wayne franchise, namely, that west of Clark Avenue, runs for twenty-three years instead of for eleven years and three months as does the portion east of Clark Avenue, and that portion of the line had net earnings of $30,307.29 last year, or 4.52 per cent of the total earnings of the Citizens' system; 4.52 per cent of $229,016.24 interest charge is $10,351.53. The same percentage of the net earnings of the tenth year of the whole system, namely, $922,845.51, is $41,712.62. During that year we must not only count, however, four months as not already included in the eleventh year in the previous computation of ten years and eight months. Continuing the same basis of reckoning as in the case of the Detroit Electric Railway, and the main franchises of the Citizens' systems, we reach the following result:

Monopoly value of the western portion of the Fort Wayne & Belle Isle system, after ten years and eight months:

Remainder of eleventh year	$ 7,145.39
Twelfth year	21,893.37
Thirteenth year	21,941.80
Fourteenth year	22,183.63
Fifteenth year	22,420.12
Sixteenth year	22,656.77
Seventeenth year	22,848.80
Eighteenth year	23,040.46
Nineteenth year	23,234.85
Twentieth year	23,435.42
Twenty-first year	23,592.11
Twenty-second year	23,757.77
Twenty-third year	23,936.78
Total	$283,087.27

The total monopoly earnings, then, of the portion of the Fort Wayne system west of Clark Avenue during the balance of the franchise is $283,087.27.

The Grand River Avenue system runs sixteen years and nine months from now. It had net earnings in the year ending April 1, 1899, of $161,615.38, or 24.12 per cent of the total earnings of the Citizens' system; 24.12 per cent of the entire interest charge of $229,016.24 on that system is $55,238.72. The same percentage of the total profits of the Citizens' system ten years hence, $922,845.51, is $222,590.34. There were only four months of the eleventh year, however, not included in the computations of the first ten years and eight months of the entire Citizens' system. The methods adopted above will give the following result for the remainder of the franchise of the Grand River system.

Present monopoly value of the Grand River system after ten years and eight months:

Eleventh year	$ 38,129.22
Twelfth year	115,761.35
Thirteenth year	117,087.08
Fourteenth year	118,377.59
Fifteenth year	119,644.92
Sixteenth year	120,902.42
Three-quarters of the seventeenth year	92,334.21
Total	$722,236.79

The main line of the Woodward Avenue expires in ten years and eight months, but the portion north of Pallister Avenue or thereabouts is a perpetual franchise, and is growing in traffic more rapidly than most of the city. It is also claimed by the company that if it should fail to secure a renewal of its main line on Woodward Avenue, it could build a short spur just north of the city limits to the Detroit Electric Railway line, which runs for twenty-six years, and thereby get to the heart of the city. It has been thought well, therefore, to compute the monopoly earnings of the Woodward Avenue line at 4 per cent for twenty-six years; that is, for fifteen years and four months after the expiration of the main line of the Citizens' system. This portion of Woodward Avenue now has net earnings of $44,077.72, or 6.58 per cent of the total earnings of the system. This percentage of $229,016.24 makes the interest charge to be apportioned to that part of the system $15,069.27. Likewise, 6.58 per cent of the net earnings of the whole system the tenth year, $922,845.51, is $60,723.24. Using the same methods as previously, the following result is reached.

Present value of monopoly earnings of Woodward Avenue north of Pallister Avenue after ten years and eight months:

Remainder of eleventh year	$10,365.44
Twelfth year	31,580.00
Thirteenth year	31,941.67
Fourteenth year	32,293.72
Fifteenth year	32,639.45
Sixteenth year	32,982.50
Seventeenth year	33,262.07
Eighteenth year	33,541.08
Nineteenth year	33,824.07
Twentieth year	34,116.06
Twenty-first year	34,344.16
Twenty-second year	34,585.38
Twenty-third year	34,845.93
Twenty-fourth year	35,132.63
Twenty-fifth year	35,358.67
Twenty-sixth year	35,519.09
Total	$516,331.92

This $516,331.92 is thus the present monopoly value on the above basis of that portion of Woodward Avenue north of Pallister, after ten years and eight months.

The last system to be considered is that of the Grosse Pointe line, east of Concord Street. This line also has a perpetual franchise, is one of the most rapidly growing lines in the city, and has a connection on Concord Street with the Detroit Electric Railway, which it can use for twenty-six years, although its direct connection on Jefferson Avenue expires in ten years and eight months, and on Congress Street in sixteen years and nine months. The net earnings of this Grosse Pointe line in 1898-99 were $33,365.04, or 4.98 per cent of the total of the Citizens' system; 4.98 per cent of the $229,016.24 interest charge is $11,405, and the same percentage of $922,845.51 gives the computed net earnings of the eleventh year of this road as $45,956.71. Taking the same basis of computation as in the previous cases, we have the following result:

Present worth at 4 per cent discount of the monopoly earnings of the Grosse Pointe line from ten years and eight months to twenty-six years hence:

Remainder of eleventh year	$ 7,872.27
Twelfth year	23,900.29
Thirteenth year	24,174.01
Fourteenth year	24,440.46
Fifteenth year	24,702.52
Sixteenth year	24,961.76
Seventeenth year	25,173.35
Eighteenth year	25,384.47
Nineteenth year	25,598.73
Twentieth year	25,819.72
Twenty-first year	26,009.88
Twenty-second year	26,174.92
Twenty-third year	26,372.11
Twenty-fourth year	26,589.10
Twenty-fifth year	26,760.17
Twenty-sixth year	26,881.58
Total	390,815.34

Thus the total monopoly earnings of the Grosse Pointe line on

the above basis, after ten years and eight months, may be computed at $390,815.34. This Grosse Pointe line increased 9.3 per cent in 1898 over 1897, and the Woodward Avenue line 7.91 per cent in net earnings, while the Fort Wayne increased 5.7 per cent, and the total increase for the whole city was 7.15 per cent. The actual net earnings were made the basis of the above computations, except in the case of Woodward Avenue north of Pallister, and in the separation of the Fort Wayne system into the division east and west of Clark Street. In these two cases the railroad kept no data, except the number of miles traversed by the cars during the last year on the separate divisions of Woodward Avenue and of the Fort Wayne system. But as the number of cars is regulated as closely as possible to the amount of traffic, it is a pretty fair test of net earnings, except as between lines like the Detroit Electric and the Citizens' where different rates of fare are charged.

No attention has been paid to the franchise value of the Michigan Avenue line west of Livernois of 4.36 miles, which has a twenty-eight-year franchise, nor of a long franchise on Mack Avenue of 1.53 miles. The latter, however, is not considered especially valuable.

We may sum up the results thus far by saying that the monopoly or franchise earnings of the various systems have the following value at present on the basis of 4 per cent increase.

Present worth of franchise earnings and of conservative prospects of growth:

Detroit Electric Railway	$1,834,736.74
Citizens', for ten years and eight months	4,691,537.27
Fort Wayne east of Clark Street, from ten years and eight months to eleven years and three months	39,818.53
Fort Wayne west of Clark Street, from ten years and eight months to twenty-three years	283,087.27
Grand River system, from ten years and eight months to sixteen years and nine months	722,236.79
Woodward Avenue north of Pallister, from ten years and eight months to twenty-six years	516,331.92
Grosse Pointe, from ten years and eight months to twenty-six years	390,815.34
Total	$8,478,563.86
Value of physical plant	8,000,000.00
Total	$16,478,563.86
Total value of physical plant and franchise, detroit Electric Railway	$4,109,330.74
Total value of Citizens' system	12,369,223.12

The above basis of reckoning has been accepted as correct by the commission and by the street railway, with the possible exception of some doubt as to the value of the Fort Wayne, Grand River, Woodward Avenue and Grosse Pointe lines, after ten years and eight months. The total on the basis taken in this computation, including all these lines, at the normal rate of growth of the whole system, is $16,478,563.86, or about $16,500.00.

This is practically the same result as would be obtained by reckoning the average life of all the franchises as a whole at sixteen years, nine months.

In the discussion of three-cent fares which follows, it is held that it would be probably wise to reckon on its taking about five years under such reduced fares to get back to the present rate of profits. Applying that to this calculation, it would appear that if the system is worth to the present owners $16,500,000, it is worth that to the city, less a postponement of five years, and plus the value to the people of a reduction of 1.1 cents per passenger, since the present fares average 4.2 cents for the 44,981,091 revenue passengers in the year ending April 1, 1899. The latter saving in fares would be about $500,000 a year to the people, therefore, on the present basis of traffic, or much more than the value of the five years' postponement.

Further calculation has been made of this kind. Suppose that during the next five years the net earnings of the system under three-cent fares only average the same as now, $750,000, being perhaps reduced to $500,000 the first year, and rapidly growing until the average of the five years was $750,000. We may even assume that the sixth year the net profit was only $780,000, and that it increased at 4 per cent thereafter. Assume further that every year from the start the city was obliged to pay $700,000 as interest at 4 per cent on any bonds issued for the plant, but in the first five years was only able to pay into the sinking fund sufficient to buy $250,000 of those bonds, the sixth year, to buy the difference between $780,000 and $700,000, or $80,000; the next year the difference between $780,000 compounded at 4 per cent, or $811,200, and $700,000 or $111,200, and so on for thirty years. At the end of this thirty years the city would have paid for $15,153,806, and in two years longer would be able to pay off $3,000,000 more, if that much were still due. However, I am decidedly of the opinion that it would be wise for the city to insist on having forty to fifty years for paying the bonds, with option of paying them at will sooner, and cancelling the security franchise. The great reason why it is proper for the city to take forty to fifty years while conceding to a private company only thirty years is that a private company is never known to the world over to attempt to repay to its stockholders and bondholders the value of the physical plant. That continues as an investment for the earning of profits. But in this Detroit case the commission is obligating itself to cancel the entire principal or cost of the physical plant, looking forward thus to the time when it will be no longer necessary to earn any interest or sinking fund charge, and when, therefore, fares may be reduced even to two cents or less. Further, in order to introduce three-cent fares, the city must count on the possibility of some reduction of earnings for three or four years, and a very heavy increase thereon afterwards, much beyond probably the normal rate of 4 per cent assumed above, unless contingencies now unforeseen should arise. It is therefore in the interest of the city to avoid any danger of defaulting on its bonds during the first few years, and this could best be secured by making the early payments into the sinking fund as small as possible.

THREE-CENT FARES

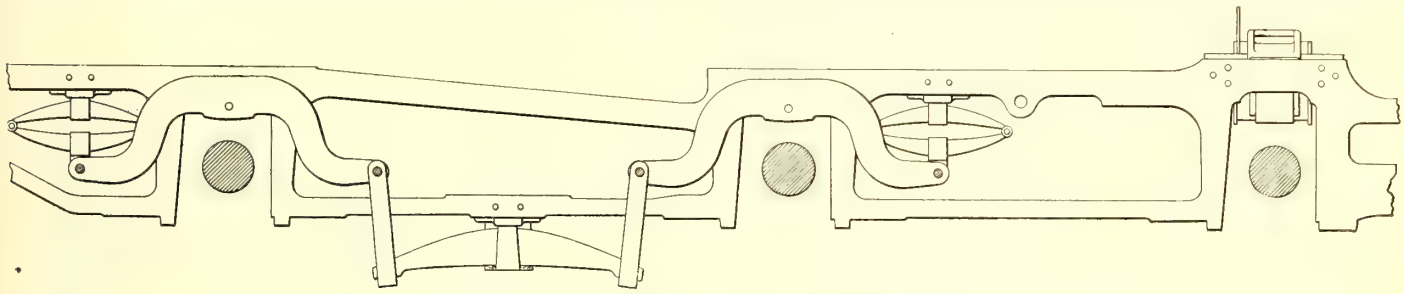
With regard to three-cent fares, I would say that the gross receipts per mile of track during the first seven months of 1897, under present rates of fare in the Citizens' Company, were $6,403. For a similar period in 1896, with fares of 3.45 cents, or .8 of a cent less than the year later, the receipts were $6,086 per mile of track. If we assume that the traffic in 1896 would have been fully 6.3 per cent less than in 1897, the receipts of 1896 would have been expected to be only $6,023, or 1 per cent less than they actually were. Since scarcely any increase per car mile of track was required to take care of this increased traffic, this basis of computation is not far out of the way, although in the course of years, increase of traffic would require some increase of equipment, and, therefore, of the interest charged per mile of track.

While the gross receipts were favorable under eight tickets for a quarter, because of the fact that increased traffic met reduced fares, the greater number of stops that the car must make per mile to take on and let off the larger number of passengers, the 1-7 more passengers per car mile and other reasons led to the fact that the expenses per mile of track in 1897 were $3,326, and in 1896 were $3,691, so that the net profits per mile of track, which were $3,077 per mile of track in 1897, were $2,395 in 1896, leaving a reduction of $682, that is, 28.3 per cent of the $2,395. Assuming that traffic would increase no faster under three-cent fares than it has done under four-cent fares, namely, 6.3 per cent yearly, it would have required about four years to have brought receipts per mile to the amount actually received in 1897, $3,077, that is, it would take four years to secure one year's gain, and it would require a fifth year, and possibly a sixth, to recover the losses of the first two years of the reduced fares. To-day the average receipts per passenger on all of the lines are 4.1 cents, although on the Citizens' line they are 4.244 of a cent per passenger. It should be stated that when the reduction was made in 1896, the state of war between the Citizens' and the Detroit Electric Railway compelled the Citizens' Company, according to their claim, to disregard many economies in the running of cars, which ordinarily would have been secured, and second, that since no one secured the advantage of cheaper fares except by ticket it did not reach the masses, who do not, as a matter of fact to-day, buy tickets by the quarter as much as do the rich and well-to-do.

This indicates considerable possibility of development of railway transportation with a straight three-cent rate.

Again, owing to the war then under way between two Detroit companies, a boycott was enforced against the Citizens' Company by many sympathizing with the efforts of the then Mayor, Mr. Pingree, to introduce low rates through the new Detroit Electric Railway. I should think, however, that it would be fair to consider that the average profit for the first five years under three-cent fares, would be about the average profit of the year just closed, namely, $750,000. It might be, of course, a little less, but could not be alarmingly so. A reduction of one cent of fare on the present 45,000,000 passengers would still leave $300,000 out of the $750,000, and, inasmuch as the traffic this year is already about 10 per cent more than last year, and would undoubtedly jump very much more than that for a while under three-cent fares, that item of increase alone would probably double this $300,000 in five or six years, to say nothing of various economies which would follow the increased traffic and saving incidental to municipal operation. And then in about five years the city might reasonably count on a 4 per cent rate of growth of net earnings upon $750,000. Giving 50,000,000 and more passengers yearly, a one-cent gift means half a million dollars a year, or 5 per cent on $10,000,000,

and when the traffic doubles, of course the benefit to the public would be proportionately increased. The people must pay the existing rate of fare to somebody for an average of seventeen years at least under private ownership, or give an equivalent for it in giving a company the right to exist during twenty or thirty years longer with a new franchise at higher rates of fare than the actual cost of transportation in future would render necessary.



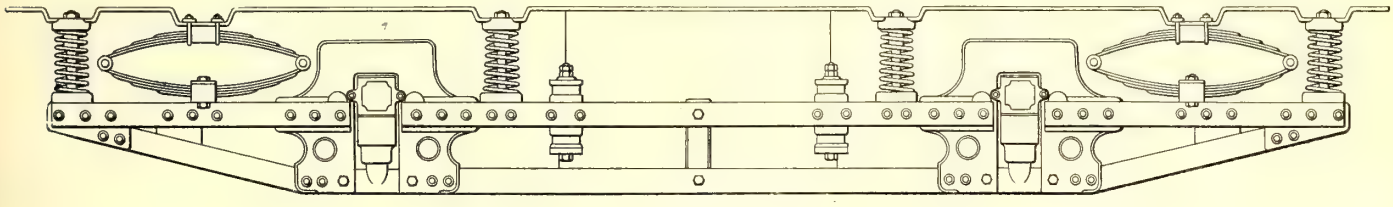
With regard to the practicability of universal transfers, I would say that while I have not much data on the transfer question, it has not seemed likely that universal transfers would diminish revenues more than they would increase them in the long run, because transfers would encourage many to ride who now walk.

EDWARD W. BEMIS.

The Functions of the Electric Truck II.

BY EDGAR PECKHAM

In the June issue of the STREET RAILWAY JOURNAL I took the position that the electric truck and the framing of a locomotive were not comparable, because of the difference in the burden and the duties imposed upon them. That I may still further substantiate this position, I have taken the framing of the Brooks express passenger locomotive of modern type, illustrated in the May issue, and propose to show that the horizontal and vertical stresses are very different in their ratios and intensities from that imposed upon an electric truck.



SIDE VIEW OF FRAMING OF BROOKS LOCOMOTIVE

Attention has already been called to the fact that an electric car is merely called upon to propel itself with an occasional trailer, while the locomotive is designed and intended to haul a heavy load, while its own propulsion is merely an incident to the work by which its earning powers are measured. In the case of the locomotive under consideration the cylinders are 18 ins. in diameter, with a piston stroke of 26 ins. With a steam pressure of 180 lbs. per square inch, this piston will produce a horizontal stress upon the frame of 45,800 lbs.; a stress that must be carried from the cylinder back to the front driving wheel pedestal, beyond which it is reduced for distribution to the other wheels. But there are positions of the crank when the whole of this enormous force must be carried by the frame back to the main driving wheel pedestal, a distance of 12 ft., so that the frame must be constructed with all the elements of a column capable of sustaining that load without buckling. Under such circumstances it is essential that the frame should have a high degree of lateral, as well as vertical stiffness. The former is obtained in the case in hand by using bars 4 ins. wide, and the latter by using two bars, thus obtaining a total depth of 23½ ins. between the pedestals, which is amply sufficient to meet any demands that may be made upon it. This is the American practice, and it is rapidly coming to be considered the best, though it is by no means universally acknowledged to be so. The plate frame must be stiffened laterally in order to meet these demands.

In the matter of vertical stresses the case is quite different. The front end of the frame carries no load whatever. The whole of the weight of the cylinders, the smoke-box and the front end of the boiler, with all of the extra attachments, such as the pilot and the like, at the forward end, rest directly upon the truck and the front drivers without any intervening vertical stresses on the frame. In fact, the whole front end of the frame is *carried* by the cylinder castings, and the only demands that are made upon it vertically are that it should have sufficient strength to carry its own weight; a condition that is very easily fulfilled, and which does not call for the great width and depth that are always given to these frames.

The rear end of the frame carries the back end of the boiler, and it is here that the only vertical stresses of the structure are to be found. Let us see how these weights are distributed. The bottom of the fire-box rests at two or three points on top of the upper rail, back of the main driving wheel. The frame itself is carried on three points. The equalization is such that one-half of the burden is carried by the two outside springs, and the other half by the one in the center. It will be seen, from an examination of the engraving, that the rear support is located directly beneath the fire-box, so that the vertical stress upon the bar of the frame at that point is merely a crushing stress upon the metal, and need not be considered. At the front end there is the same weight to be carried, and this does put a vertical stress on the frame. It comes from the weight of the frame itself, and that portion of the fire-box weight that is carried forward to it. As the distance out to the point of support is short, and as the stress is carried to it by that portion of the frame which is the heaviest, it may be disregarded and our attention turned to where the greatest stresses are to be found.

It will be seen that this is at the central portion, and that one-half of the total weight imposed upon the driving boxes is carried on the lower rail running between the pedestals of the main and rear drivers. This rail has a width of 4 ins., a depth of 2½ ins., and a length of 5½ ft., that may be attributed to this section. The stress put upon the rail is well within the elastic limits of the iron from which the frame is forged, as the load imposes a fiber stress of less than 6000 lbs. per square inch upon the metal when standing, and which does not rise to more than 9000 lbs. under the most unfavorable conditions of running, for the actual static load carried at this point is about 10,500 lbs. To this, 50 per cent may be added for the running load when moving over a rough track.

SIDE VIEW OF FRAME OF CANTILEVER TRUCK

It appears, then, that the builders of the modern first-class locomotive fully realize that the duty of the frame is to haul a load and not to carry one, and they therefore design accordingly.

Let us now consider the electric truck. The framing illustrated is that used to carry the ordinary electric car. The conditions are that it shall carry a car body weighing about 8300 lbs., and in addition thereto about one-half the weight of two motors, or 2500 lbs. more, which is distributed on two points of support. To the weight of 8300 lbs. must be added that of the passengers, which may be taken at 15,000 lbs. more, for a maximum, making a total of 25,800 lbs., which, owing to greater liability to track inequality than in the case of steam roads, should, with the motor weight, be increased by 50 per cent. This gives a total running load to be carried by the truck of 38,700 lbs., making a running load of 9675 lbs. for each axle box.

Again, as the total weight of the loaded car, including wheels and axles, is about 33,100 lbs., we may take one-quarter of this as the effective weight at the rail for each wheel. If we assume the

coefficient of friction between the wheel and the rail to be .35, the propulsive force exerted by each wheel at the rail will be:

$$\frac{33{,}100 \times .35}{4} = 2721.25 \text{ lbs.}$$

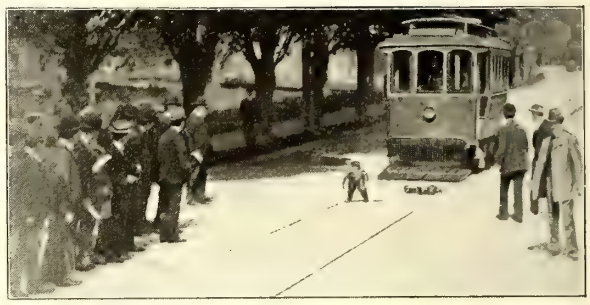
Deducting that due to the wheel and one-half the motors, which are taken to be equal to 1100 lbs., and treating this weight in the same way, we have 2336 lbs. as the propulsive effect of each axle box upon its pedestal; a thrust whose intensity is divided between the cantilever overhang and the central portion of the truck, in proportion to the weights carried on these parts respectively, and which will now be shown.

Reverting the vertical stresses which the cantilever truck is called upon to sustain, and which it is capable of sustaining, carefully conducted tests have shown that the cantilever will sustain a load of 5 tons at a distance of 38 ins. from the center of the oil box without being strained beyond its limit of elasticity, showing no permanent set after the removal of the load, while a load of more than 10 tons was required to buckle the lower bar and distort the frame. This places the sustaining power of the cantilever truck frame at 190 inch tons, or 380,000 inch lbs.

With the ordinary running load of 9675 lbs. per wheel, that has been assumed, the spring deflection ordinarily used has been found to be 2⅜ ins. The weight is carried by three helical and one elliptic springs. Calibrations of these four springs show that the stresses applied by them to the frame, when deflected 2⅜ ins., are as follows:

	Pounds.
Helical spring between boxes	2,753
Elliptic	2,749
Intermediate helical	2,753
Outer helical	1,420
	9,675

The distances of the elliptic, the intermediate helical and the outer helical springs from the center of the axle box are 22 ins., 38 ins. and 47 ins. respectively. Multiplying these weights carried by the springs by their several distances from the axle center, we find that the total running load upon its cantilever is 231,832 inch lbs. or exactly 61 per cent of a load that is still within the limits of elasticity of the structure.



What I wish particularly to emphasize at this point is the fallacy of that position which assumes that the stresses upon a locomotive frame and that of an electric truck are at all comparable. I have shown that the horizontal stresses in the former amount to 45,720 lbs., which must be sustained by a column 12 ft. long, whereas in an electric truck the horizontal stress on the cantilever is but 2336 lbs., divided into items of less than 800 lbs. each, located at distances of 20 ins., 36 ins. and 45 ins. from the base. When the relative dimensions of the column are considered, any comparison of the horizontal stresses imposed simply become ridiculous.

The same absurdity appears when the vertical stresses are taken into account. With the locomotive having a total weight of 130,000 lbs. the greatest vertical stress on the frame is 10,000 lbs., while the horizontal thrust is 45,720 lbs., or a ratio of .24 to 1. In the case of the electric truck, on the other hand, with a total weight on the wheels of 33,100 lbs., the vertical stress amounts to 6922, while the horizontal stress is but 2336 lbs., giving a ratio of 3 to 1, or a difference in ratios of about 1 to 12. It is no wonder, then, that the lines upon which the framing of the locomotive and the successful electric truck have been developed are quite different. They are intended for different purposes, and naturally they do not and ought not to resemble each other either in design or in the distribution of the metal of which they are composed.

Now, as to the durability of the riveted cantilever truck frame. The first Peckham cantilever trucks of their present design were furnished to the Brooklyn City Railway, of Brooklyn, in 1892, for use under its 20-ft. closed (28 ft. over all) cars. As these were the first electric cars constructed of this length, they were considered experimental, it being a question as to the ability of a single truck with a 7-ft. wheel base to support a 20-ft. closed car. To determine this and the truck best adapted for the purpose, the Brooklyn City Railway gave every truck maker an opportunity to test his truck under these cars, and ten or eleven different styles of trucks, including the solid forged truck, were represented. As the result of this trial the Peckham extra long cantilever truck was adopted, and over 1200 were supplied to the Brooklyn City Railway during the years 1893, 1894, 1895, all of which are now in service. The rivets in these trucks are still tight, and give no evidence of becoming loose. Twenty-five trucks of this design were also furnished to the Broadway Cable Railway in 1893 for use under its 22-ft. closed (30 ft. over all) cars, and have been in constant use, winter and summer, ever since, and no trouble has been experienced on account of broken or loose rivets, although at that time the riveting was done by hand instead of by pneumatic power, employed the past four years. Considering the severe service to which they have been subjected under these heavy cars, which are frequently overloaded, the fact that they have run such a length of time (seven years) without the rivets becoming loose demonstrates the shallowness of the claim that the rivets are an element of weakness, and likely to work loose as a result of the jars to which they are subjected, and also as to the ability of the cantilever truck to successfully support a 20-ft or 22-ft. closed car under the most severe conditions. As to the comparison of the service between the cantilever and the solid-frame trucks, it would be very interesting to know the history of the solid-framed trucks put into service in 1892 and 1893, and how many changes have been made in their design and construction since that time to overcome their demonstrated defects, and also as to their ability to carry 20-ft. or 22-ft. car bodies without the aid of an auxiliary pipe truss, which is never used under closed cars with the cantilever truck.

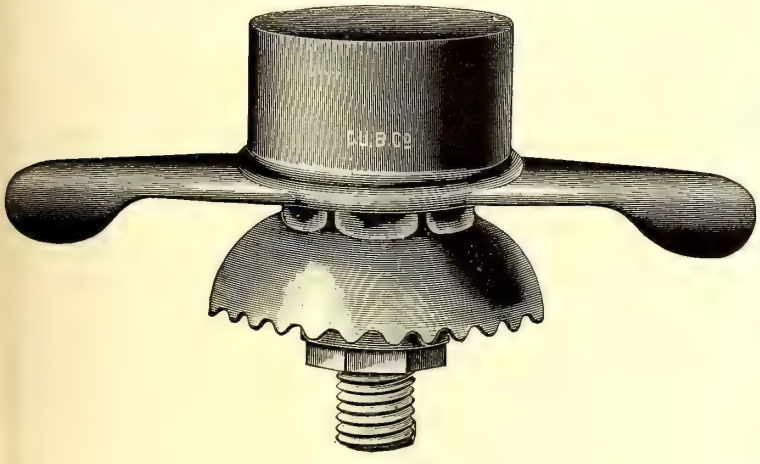
Photographing a Fender Test for the Mutoscope

In these days of business activity, when Yankee genius and energy are being taxed to the utmost to develop new and successful methods of increasing trade and selling goods, an idea, to deserve special mention, must be exceedingly novel and valuable. To the

VIEWS SHOWING FENDER IN SERVICE

Hipwood-Barrett Car & Vehicle Fender Company, of New York, however, unquestionably belongs the credit for furnishing one of the cleverest and most unique schemes of advertising that has appeared for some time.

This company's fender has been in operation for about twelve months on the Newton & Boston Street Railway, of Newtonville, Mass., and in that time has fully demonstrated its value as a life-saving device. So sure were the inventors that the fender would pick up any object in its way under all conditions that they opened negotiations with the American Mutoscope Company for taking photographs of a practical demonstration of the device, for re-



production in the mutoscope and biograph throughout this country and Europe, on the grounds that a moving picture of this kind could not fail to excite general interest. These negotiations were successful, and on May 10 a very satisfactory test of the fender was made at Newtonville, and photographed by the mutoscope camera. The picture secured makes one of the most interesting views owned by the Mutoscope Company, and will be shown in nearly every city in America and in the largest cities abroad. It was shown at Boston, and also daily for two weeks at Keith's Theatre in New York, to large crowds, who never failed to manifest special interest when it was thrown on the screen. The fender company also has a mutoscope at its New York office, showing the test. Although taken primarily for its popular interest, the picture is, of course, a splendid advertisement for the Hipwood-Barrett fender, and the company is to be congratulated on its enterprise in arranging the details for the mutoscope demonstration. While the views were being shown in New York, representatives from nearly every street railway company within a radius of 25 miles accepted invitations from the fender company to attend the performance at Keith's, and, of course, saw about as forcible an argument as to the ability of the device to save life as could be desired.

Some of the details of the demonstration will be of interest. Two dummies stuffed with sand and sawdust were employed, one weighing about 30 lbs. and the other about 50 lbs. The smaller one was laid upon the track with its head upon one rail, and one of its arms extending out in the direction from which the car was coming. It is particularly noteworthy that this arm was only about 1 in. in diameter. The other dummy was placed about 10 ft. from the first, and in a standing position. The car was started at full speed, nearly two blocks from where the dummies were placed, and was going at about 15 miles an hour when it reached the spot. The fender was dropped 1½ ft. from the first dummy, and picked up both of them without the slightest difficulty. No marks or tears of any kind appeared on the bodies. The mutoscope camera was directed toward the car through the entire operation, and every detail is very clearly brought out in the picture. The photographic film was 160 ft. in length, and there were 1200 separate views. It took just twenty-seven seconds to complete the test. In the accompanying engravings are shown three of the scenes that go to make up the complete picture.

Straight Line Hanger

The accompanying illustration shows a straight line hanger known as "The Gem," manufactured by the Central Union Brass Company, of St. Louis, and sold through the Central Electric Company, of Chicago, as general agents.

The hanger was designed on the well-known West End lines, but changed so that, it is claimed, there is no possibility of trouble

"THE GEM" STRAIGHT LINE HANGER

from the loosening of the cap which holds the insulated bolt in place, due to the continual vibration of the trolley wire.

It will be noticed that this hanger has no cap to jar loose, the skirt of the hanger being that part which holds the insulator bolt in place by the pressure of the span wire against the corrugation in the neck of the skirt. The skirt in the hanger has a fluted or beaded edge, which, in heavy rain storms, forces the water to run off in streams, therefore cutting down the leakage to a minimum. In this manner of construction it is possible to make several combinations of materials, such as using a malleable iron body with a bronze skirt, or malleable iron skirt with a bronze body or all iron or all bronze. The threaded portion of this hanger is so well protected that it is absolutely impossible for any moisture to get through into the insulation.

When double-petticoat glass insulators were first placed upon the market they became a universal standard, owing to their having less leakage than any other insulator made at that time.

The beaded skirt of "The Gem" is claimed to offer the same amount of protection against the leakage of current as the double petticoat does to the glass insulator.

Mechanical Power Brakes

The subject of brakes is one of the most important to be considered in the equipment of the modern electric railway. That the increased weight and high speed of the modern motor car demand a more powerful and effective brake than was necessary for slow-moving horse cars is generally admitted. Since the general adoption of electricity on street railways, various brakes have been put on the market, operating by compressed air, electricity and other agents. One of the most widely adopted substitutes for the old-fashioned chain and spindle brake is the Sterling safety brake, made by the Sterling Supply & Manufacturing Company, of New York, and introduced about five years ago. Since that time the brake has been extensively adopted, and its reliability and efficiency proved in service. A severe test of this brake has been made at Troy, N. Y. The line of the Troy City Railway extends for the greater part of its distance over a series of grades, some of them being over 10 per cent. The company has from thirty-five to forty of its cars equipped with the Sterling brake, and the management states that it is fully efficient and reliable. The brakes have also been used for three years by the Buffalo Railway Company, which has had seventy equipments. The Sterling Company also reports brakes in use in Rochester, N. Y.; Worcester, Mass.; Manchester, N. H.; Indianapolis, Ind., and many other cities. Its salient features are safety, ease of operation, great power and durability, and these advantages are realized with extreme simplicity of design.

It is, strictly speaking, a mechanical power brake, and is made up of a double sprocket wheel carrying two continuous chains and geared to the brake staff. The ratio of gearing is sufficient to afford easy and positive operation without sacrificing quickness of action, multiplying the motorman's power and enabling him to manipulate the brake shoes so as to greatly overcome the sliding of wheels. The wear on chain and gears is reduced to the minimum, being equally distributed, and there is not the continual "grinding," wearing through and replacing of chain, common to the ordinary brake. This is quite an important item, as the old-fashioned chain on a spindle shaft wears out on an average in from four to ten months, and costs considerable for maintenance. The Sterling brake is also adaptable to either single or double truck cars, and can be easily applied to old as well as new cars. With this device the motorman is enabled to control the car in any emergency with comparative ease.

Naturally it is argued that heavy cars and heavy grades create the principal demand for safetey brakes, and in service, the Sterling brake has proven fully effective as a medium of safety on heavy cars and grades. However, its adoption and use has not been limited to roads having heavy grades, as experience has proven to the majority of managers that even on a level, or a slight grade only, emergencies arise which require more safety and efficiency than is afforded by the ordinary brake. Hence the Sterling safety brake has been adopted, not alone because of its efficiency on heavy grades, but on any grade, and because of the medium of safety it affords against accidents, and suits for damages consequent thereto.

Sales of Hose Bridges

The portable hose bridge manufactured by the Ohio Brass Company, of Mansfield, Ohio, and which was described in the last issue of the STREET RAILWAY JOURNAL, is meeting with an increasing demand. The manufacturers report recent sales among some of the largest and best known street railway companies in the United States, bridges having been shipped within the last month to the Syracuse Rapid Transit Company, Chicago City Railway Company, Toledo Traction Company, Nashville Street Railway Company, Knoxville Traction Company, the People's Railway Company, of Dayton, Ohio, and numerous others.

The Provincial Council of Macerata, Italy, has voted a subsidy to the town of Camerino to construct an electric railway between that city and Castelraimondo.

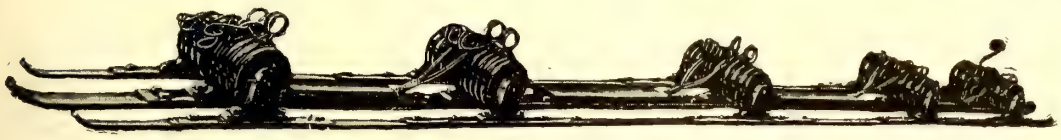
Surface Contact System at Tours

The tramway company of Tours, France, has recently installed the Diatto surface contact system for electric railways, and the first section of this line was put in operation April 22, before a large assembly of French electrical engineers and tramway managers. Considerable interest has attached to this system, owing to its adoption on such a large road, as the tramways in Tours measure 23 km. (14 miles) in length, and of this 12 km. (7 miles) will be equipped with the surface contact system, and the rest with the trolley system.

The principle of the Diatto system consists in the operation of a plunger by magnets carried on the car, the plunger making contact between the main source of supply and a surface knob, from which the current is taken by a skate to the motors. The special features of the system consist mainly in the method of improving the magnetic circuit about the plunger, so as to secure better control over it from the car.

A section of one of the contact boxes is given on page 487. The upper part of it consists of a block of asphalt, in the center of which is a button, *C*, of soft iron, resting in a flange, *A*, of bronze or other non-magnetic metal. The button *C* terminates in a carbon contact point, *D*. The plunger, which is of iron with a carbon head, is shown at *K*, and slips inside of an ebonite tube, which is partially filled with mercury, so that the plunger floats normally in the position shown in the cut.

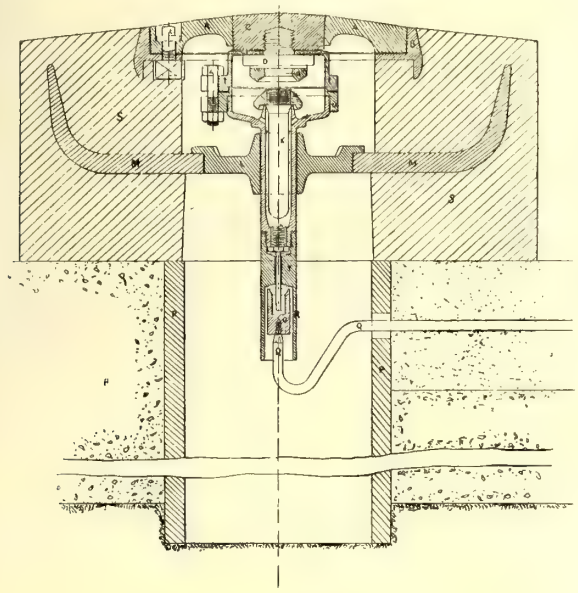
SECTION OF COMPLETED TRACK



LAYING THE TRACK

The lower part of the mercury is connected with the main source of supply, *Q*, and at the upper end of the plunger is a carbon contact button of proper shape to engage with the button *D*. On each side of the plunger tube are two large soft iron wings, *M*, embodied in the asphalt, and with upturned extremities, so as to assist in completing the magnetic circuit as they are turned up toward the magnets carried on the car.

The skate, or collector, on the car is composed of three bars with upturned ends, as shown on page 487, between which is mounted a set of electric magnets, so arranged that the central shoe will be of north polarity, while the outside shoes are of south polarity. When carried on the car the central shoe passes directly over the contact knob and the outside shoes over the extremities of the flanged magnetic yoke in the asphalt. The plunger will then be attracted upward, when it will be brought into contact with the carbon button on the surface knob, and current will be taken into the cars through the central shoe.



After the car has passed, the plunger drops down to its original position by gravity. Owing to the curved shape of the ends of the contact shoes, it is claimed that the electrical contact will be broken before the magnetic circuit. Consequently, any arcing which may occur from breaking the circuit will take place between the shoe and the contact button, and not inside the contact box, as no current will be passing from the button when the plunger falls back to its original position by gravity. It is claimed, however, that there will be no arcing whatever, as the skates are long enough to span two contact buttons. It is claimed that the amount of residual magnetism possible to be retained by the soft iron contact block is insufficient to overcome the weight of the plunger, and that consequently there is no possibility of the latter sticking in a raised position. Nevertheless, to satisfy the City Council of Tours, the railway company has attached to every car

a short circuiting device, consisting of a grounded brush, which is carried at some distance behind the car. If this brush should pass over a live contact block it will sound an alarm and also blow the main fuse of the car. To operate the magnets at starting, a small storage battery is carried on the car.

SKATE OF TOURS CAR

The length of the line now operated in Tours on the Diatto system is 2 km., and on the trolley system, 3.6 km. The Tours Tramway Company is building a large electric power station to operate its lines. There will be three 300-h.p. engines, built by Piguet & Co., Lyons, each belted to a 200-kw. generator, supplied by the Société d'Applications Industrielles. The generators will be wound for a voltage of from 550 to 600, with 12 per cent compounding. The cars of the company were supplied by the Compagnie Générale de Construction, of St. Denis, and the material for the overhead line, rail bonds, I. T. E. circuit breakers, etc., by R. W. Blackwell & Co.

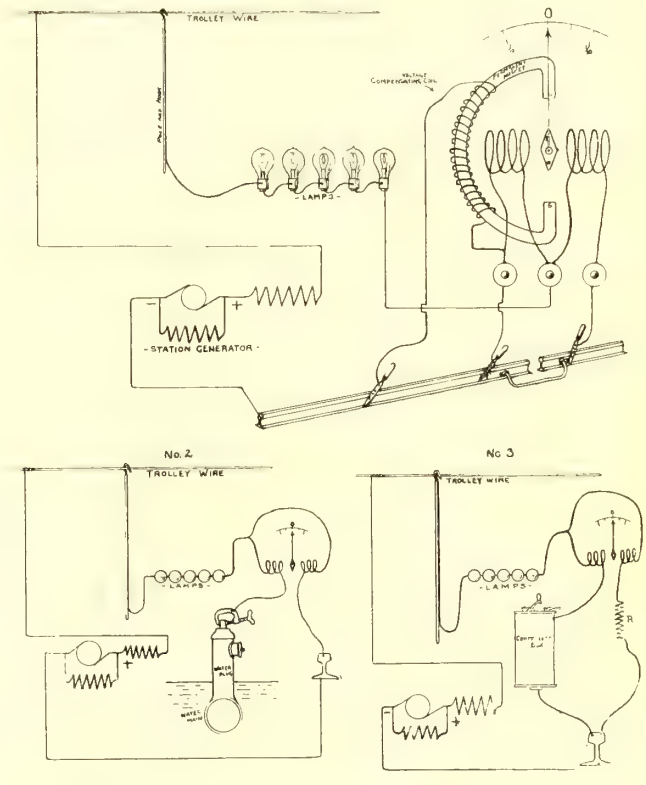
SECTION OF CONTACT BOX

The Diatto system will also be installed at Lorient and Rheims, France.

New Cars for the Chicago City Railway

The new closed electric cars for the Chicago City Railway Company, which are now being completed by the John Stephenson Company, Ltd., at its Elizabeth works, are extremely tasteful in design and finish. The cars are 20 ft. long over corner posts, and 30 ft. over all. They have concave and convex paneled sides, with body 7 ft. 6 ins. wide at belt rail, and 6 ft. 2 ins. wide at sills.

The platforms are 4 ft. 6 ins. long, and are enclosed by vestibules having three drop windows, angularly placed. The front of the vestibule, however, is curved in form below windows, and is faced with sheet steel. The platforms have entrances at both sides, and are fitted with three-part doors, folding against vestibule. The steps are pressed steel, with rubber treads. The platforms are also fitted with angle-iron buffers.



The body has six windows on each side, and all glass and sash frames are set in specially molded rubber pockets, which prevent all rattle whatever from this source. The interior finish is in cherry, stained dark, with hand-carved window and door pilasters and pressed mouldings, giving a very rich and handsome appearance. The ceiling lining is birdseye maple veneer. The seats are of the side pattern, with spring cushions and backs, covered with olive green carpet, and were supplied by the Hale & Kilburn Company. The metal trimmings are extra heavy bronze throughout.

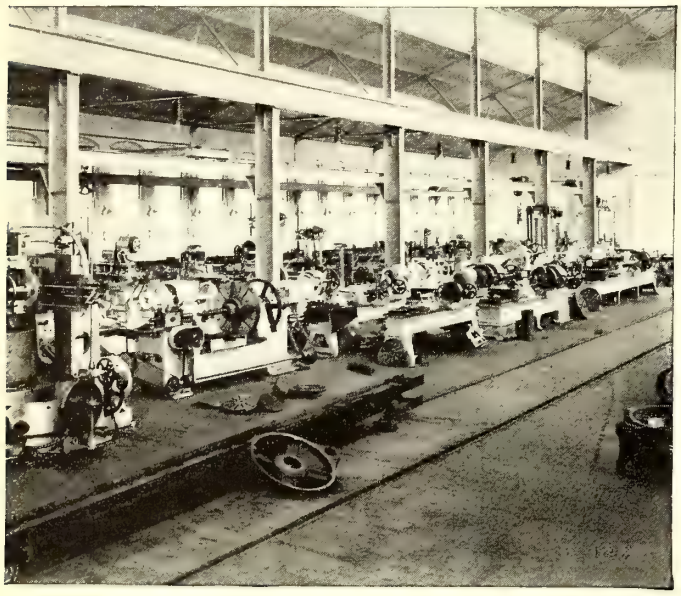
Cars are painted in olive green in varying shades, the deck sash being set in green rippled glass to match. On the hoods are Hunter illuminated signs. The cars are wired for two light circuits, *i. e.*, eight lights in the body, arranged four in each corner of the monitor and two along the sides of the monitor, and one over the door on the platforms. The cars are also wired for conductors' signal, with buzzers on each platform and push buttons in the window pilasters.

The weight of the car body is 9000 lbs., and it will be mounted on Moore electric trucks with 9-ft. wheel base, equipped with Price power brakes.

A Resistance Detector

The accompanying diagram shows a differential resistance detector recently invented by John C. Henry, of Denver, Col., for determining slight differences of resistance. Fig. 1 shows its application to track joint testing. The indicating needle is normally held at zero by a permanent magnet. One-half an amp. is taken through the instrument from trolley to ground. This current divides between the solenoidal coils within the instrument, depending upon the resistance of the joint which is being measured, and moves the needle proportionately. The coil surrounding the permanent magnet is placed in shunt with the rail, the spaces depending upon the weight of the rail, and it is intended to balance

RESISTANCE DETECTOR

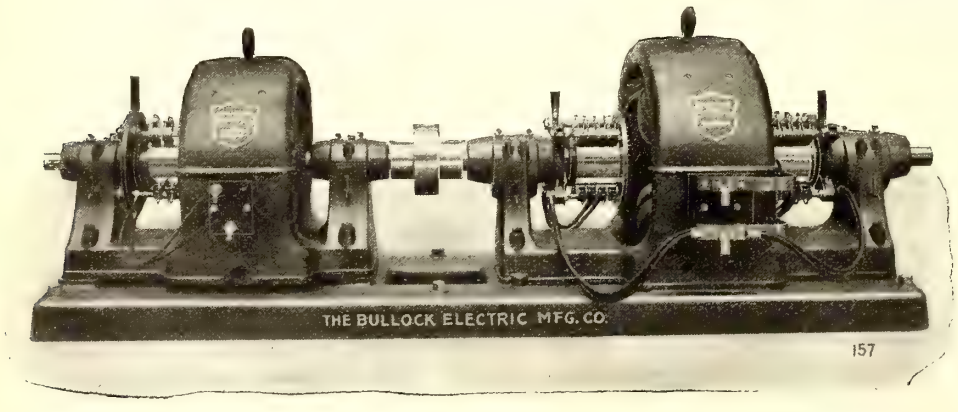


the variation in the resistance of the joint, which is caused by fluctuations of the current. For other purposes, when it is desired to compensate for drop in voltage, the coil can be connected in shunt with one of the lamps. Where the tests are made at night, when the cars are not running, the compensating coil need not be used. Where there are two bonds, one of which is in good condition and the other not, or where the current can be shunted around the bond through a cross connection, the instrument, of course, would not show the defect, but this is also true of most other detectors.

Fig. 2 shows the connections used to compare the relative conductivity of the track and water mains. In this case the deflection of the needle also indicates the direction of any current and voltage between the conductors. Fig. 3 shows the method of using the instrument to test controller connections. In this case the controller is then turned a notch at a time, and the indications noted on the dial, which should correspond with the known proper resistances of the different combinations.

Works of the Bullock Electric Manufacturing Company

The works of this company were completed last summer, and are located at East Norwood, Ohio, one of the suburbs of Cincinnati, and less than 5 miles from the heart of the city. The B. & O. S. W. Railroad cross the tracks of the Pennsylvania Railroad at this point, and both roads have switches entering the works, giving the Bullock Company excellent facilities.



The company manufactures a large variety of electric machinery, including motors, boosters and generators, and some of its apparatus has been illustrated in the columns of this paper. It has recently gone into the manufacture of large generators for railroad in sizes up to and including 800 kw. These machines are built on the same lines as the other standard Bullock machines.

INTERIOR VIEWS OF WORKS

The Bullock electric machinery is used for power distribution purposes, and throughout the works of the company there is no line shafting and counter shafting, but each machine is equipped with a Bullock electric motor. Among the tools equipped in this way are cranes, power presses, planers, drills, milling machines, hydraulic presses, boring mills, etc. The motors used for driving these tools are specially designed and adapted for the work which they have to perform. The economies effected by the application of motors to machine tools, though in the first cost slightly more expensive than the use of the line shafts, belting and counter-shafts, soon justify the additional expenditure.

BOOSTER

The power house is provided with vertical water tube boilers, and equipped with automatic stokers. A cross compound engine, directly connected to two of the Bullock Electric Manufacturing Company's engine type generators, supplies current, not only for the lighting system, but for the Bullock multiple voltage power system used throughout the entire plant. The accompanying engravings show views of the company's machine shop and a standard booster for railway work.

The Eastern Massachusetts Consolidation

The prospectus of the new "Massachusetts Electric Companies," which is a virtual consolidation of thirty-one street railway and several electric lighting companies, covering the greater part of the territory north of Boston as far as Newburyport and Gloucester, and Nashua, N. H., and south as far as Fall River, Newport and Providence, R. I., has just been issued, and is an interesting document. It is a "voluntary association," managed by a board of fifteen trustees, who hold the title to its assets. The declaration of trust contains strong provisions against the creation of any indebtedness whereby any stockholder or trustee can be held personally liable. The board of trustees includes some of the best known and most highly esteeemed citizens of Massachusetts, five of whom are elected for one year, five for two years and five for three years.

The board of trustees have issued certificates of participation to the amount of $12,000,000 in 4 per cent common shares, and $12,000,000 in 4 per cent preferred shares, and each holder of a certificate will be entitled to a proportionate interest in each and all shares of stock held by the trustees. These securities are offered at public subscription at a price of $1,050 for ten preferred shares and five common shares.

The new company controls 647 miles of track, 1426 cars and eighteen power stations, the latter having a total rated capacity of 28,423 h.p. The earnings in 1897-1898 applicable to dividends upon the new shares of the Massachusetts Electric Companies were $733,233, equivalent to a 4 per cent dividend on the $12,000,000 preferred shares, 2 per cent dividend on the $12,000,000 common shares, and a surplus of $13,232.

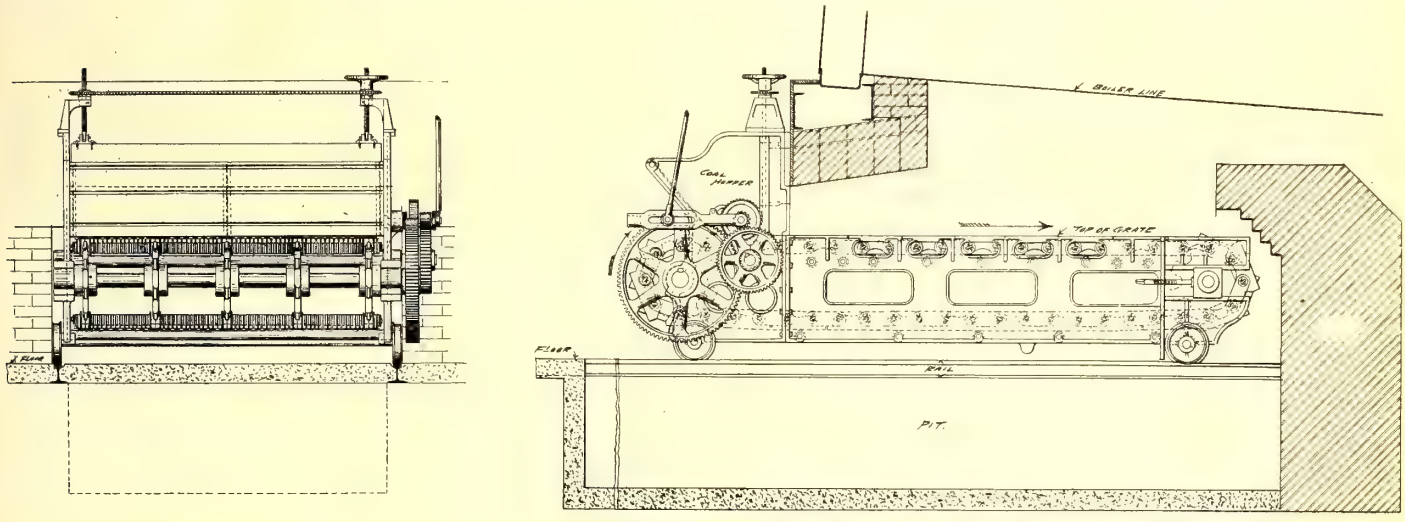
It seems reasonable to expect that by a consolidation of these properties, substantial economies can be effected, particularly in the distribution of load among the many power stations of the system.

The "Compagnie Générale d'Enterprises Electrique de Para" is the title of a new company organized May 10 in Brussels, Belgium, to operate the electric tramway and lighting system of Para, Brazil. The capital stock is frs. 1,000,000. The board of directors consists of the following: MM. Jules de Borchgraeve, manager of the Compagnie Générale Coloniale pour Favoriser l'Industrie et le Commerce au Congo; Paul Macau, of Bruxelles; André Van Iseghem, of Bruxelles; Otto Fuerth, manager of the Société La Brésilienne, of Para; Arthur Brown, consul at Londres; Fernand de L'Abre, of Antwerp.

Traveling Link Grate

In the accompanying illustration is presented an endless chain grate for boiler furnaces. This grate, while resembling in general appearance some of the traveling grates already on the market, has some special features which make it very desirable. It has now been on the market for about three years, and has been, or is being, installed in steam plants of an aggregate of 16,000 h.p. Among the recent equipments are six grates for the boilers of the new power station of the Milwaukee Electric Railway Light Company, of Milwaukee, Wis. Each of these grates is approximately 10 ft. wide and 9 ft. effective length of grate surface, making a total of 90 sq. ft. Among the largest purchasers and users are the Cincinnati Edison Company, United States Glue Company, of Milwaukee; Armour Packing Company, Kansas City; Metropolitan Street Railway Company, Kansas City; Swift & Co., St. Joseph, Mo.; Brown Building, St. Louis; West Side Street Railway Company, Chicago.

One of the principal features in which the grate differs from others of its class is that the clips or links are so formed as to be readily removed or replaced in the chain without removing cross-rods or any of the principal parts. For this purpose the clips, or links, which are about a foot long, are slotted on the underside. There are two of these slots, which are enlarged into a circular opening, and which are provided to receive the transverse joining bars. The latter are oval, and of such shape as to allow the clips to be slid over them when held in a certain position. All the clips being in place on the adjoining bars, each bar is canted so as to bring its largest diameter across the opening, and being held in this position, the links cannot drop off or be removed. The joining bars are held in this position by means of outside links, known as binders, which have slotted openings to admit the ends of the joining bars when turned to the proper angle, and which the binders hold in the same position. The binders themselves are held in place by cotter pins. When it is necessary for any cause to remove or replace these slotted clips or links, the binding links of a pair of bars are removed, when, with a wrench, the bar is partly turned, permitting the links to be lifted off and replaced, and when in position it is again brought to its proper angle and the binders replaced.



Another feature is the method of providing bearings on which the chain rides. These bearings consist of heavy steel piping, mounted at their ends upon roller bearings, the ends being reamed or recessed so that the rollers rest in the nest of bearings, thus making a double roller bearing for each roll. By this means easy and positive motion is secured without the use of lubricants. The roller bearings are housed in so that they are entirely protected from dust and ashes.

The chain is moved by means of sprocket wheels, which are mounted upon the front driving shaft, and which engage with peculiar shaped driving links, which are placed in rows in the face of the grate chain, so that the sprocket wheels engage with lugs on these special designed links. A second set of wheels is mounted on the rear shaft, which is horizontally adjustable, to provide for the chain tension. The individual clips or links are corrugated on their upper surface and are air spaced, according to the character of coal and strength of draft. The grate is mounted on an iron carriage having wheels which run upon track especially provided, and which extend in front of the boiler to permit of the grate being entirely withdrawn from the furnace without interfering with the boiler setting.

The driving mechanism of the grate consists of a train of gears actuated by a ratchet, as shown, and is operated by a lever or rod, which is connected to an eccentric upon an independent shaft. In the case of the Milwaukee plant, this shaft is located in the basement, and is operated by a small 6-h.p. engine. Besides the lever and ratchet, there is an attachment for operating the grate by hand, independent of the power connection.

A coal hopper is provided, together with a feed regulating gate, and is supported by means of the side frames of the carriage, which are extended upward. There is also a removable hopper curtain. The regulating gate is lined with fire brick, and moved up and down within vertical guides, and is operated by means of two screws, which are connected with a sprocket chain, power being applied by means of a hand wheel, as shown.

Another interesting feature in connection with these grates is the method of supporting the roof of the fire-box at igniting arch. This is composed of specially designed fire brick, having grooves which permit of their being slid over steel channel bars, which are securely supported to the brick work. By this means, a plain, slanting surface is provided above the fire, instead of the arched construction which is usually employed. The economic features of chain grates of this type are in the direction of smokeless and economical combustion, even when a low grade of bituminous slack is employed for fuel. The other features include low cost of attendance and low cost of maintenance and repairs. Recent tests made by one of these grates in the plant of the United States Sugar Refining Company, of Chicago, using Illinois crushed lump and slack, show that a 350-h.p. boiler developed power in different tests ranging from 359 h.p. up to 506 h.p., the evaporation ranging from 8.83 lbs. to 9.63 lbs. of water from and at 212 degs. evaporated per pound dry coal, with an efficiency of 73 to 77 per cent, and an average of 15 per cent Co_2 in the gases above the furnace. The coal used ranged in value from 11,500 to 12,500 B. T. U. per pound dry coal.

END AND SIDE ELEVATIONS OF LINK GRATE

These grates are manufactured and sold by the Green Engineering Company, of Chicago. This company not only manufactures grates above described, but contracts to provide a complete installation of power plants, either for electric lighting purposes, street railway plants or power plants of any description. The company is special agent for the Edgemore water tube boilers, but install any type of engines or generators. The personnel of the company includes W. M. Green, president; John R. Gent, vice-president; P. A. Poppenhusen, treasurer, and H. A. Poppenhusen, secretary. All these gentlemen have had practical experience in the installation of steam plants, having been connected with some of the leading engine and boiler manufacturers in the country.

Underground Conduits for Chicago

It is stated that the Chicago Union Traction Company, the consolidation of the North and West Side systems, will ask the municipal authorities for permission to use the underground trolley system for the lines in the down town districts, including the cable loops of the North and West Chicago Companies, and that permission will furthermore be asked to substitute the trolley for the cable on the lines north and west of the river.

Special Catalogue

The new catalogue of the Central Electric Company, of Chicago, Ill., is, as in previous years, one of the most elaborate issued by any electrical supply house. It is bound in cloth, contains 537 pages, and on every page is found from one to half a dozen cuts of some tool or apparatus used in the generation or distribution of electric currents. A complete index at the back of the book enables the intending purchaser to find the reference in the catalogue to any particular supplies he may be in need of. The catalogue should find a place in the library of every railway manager in the country.

Personal

MR. P. F. SULLIVAN has accepted the position of general manager of the Massachusetts Electric Company.

MR. MITCHELL JEANNES has been chosen general manager of the Fox River Electric Railway, of Green Bay, Wis.

MR. W. A. BELCHER, manager of the Ithaca (N. Y.) Street Railway Company, has resigned his position, to take effect July 1.

MR. J. W. BROWN has secured an interest in the Dubuque (Ia.) Light & Traction Company, and will assume the management of that property.

MR. H. F. PARSHALL, of London, has been appointed local honorary secretary for Great Britain by The American Institute of Electrical Engineers.

MR. JAMES S. FITZMAURICE, of Sydney, has been appointed local honorary secretary for Australasia by The American Institute of Electrical Engineers.

MR. O. B. VINAL is the new electrician of the Schenectady (N. Y.) Railway Company. Mr. William Steers has been appointed purchasing agent of the railway department.

MR. C. W. BLACKINGTON has resigned his position as superintendent of the Millbury division of the Worcester & Suburban Street Railway. He has held the place about a year.

MR. JOHN GRANT has taken up the duties of assistant manager of the Indianapolis Street Railway Company, having left the Detroit roads with which he has been connected for a long time.

MR. JOHN R. GRAHAM, president of the Quincy & Boston Street Railway Company, is to be general manager of the local division of the Massachusetts Electric Company, with headquarters at Quincy.

MR. E. C. HATHAWAY has taken up his duties as general manager of the recently consolidated street railway companies at Lexington, Ky. He was formerly connected with the street railway at Charlotte, N. C.

MR. THOMAS WILSON, who has had charge of the engineering work in connection with the extensions being built at Harrisburg, Pa., has accepted a position as assistant engineer with the Buffalo Traction Company.

MR. ARTHUR M. CRAM, of Walpole, Mass., who has been one of the superintendents of construction of the Norfolk (Mass.) Southern Street Railway Company, has left for Vermont, where he will engage in some important electric railway construction.

MR. W. A. HELLER, who recently resigned the position of superintendent of the Lewiston & Youngstown Frontier Railroad Company, of Lewiston, N. Y., it is stated, has accepted a similar position with the Niagara Falls & Lewiston Railroad Company (the Gorge road).

MR. C. C. LEWIS, formerly of the Pennsylvania Steel Company, has been appointed engineer of way of the International Traction Company, the recently consolidated system of electric roads of Buffalo, N. Y., and vicinity.

MR. J. A. MAXWELL, who recently resigned as superintendent of motive power with the Cortland & Homer Traction Company, goes to Troy, where he has accepted the position of master mechanic of the Troy City Railroad Company.

MR. CHARLES F. THOMPSON, secretary, treasurer and director of the Lane & Bodley Company, Cincinnati, has resigned his position in those capacities, to take effect July 1. Mr. Thompson has been with the company thirty-five years.

MR. H. C. BENAGH, superintendent of the Savannah, Thunderbolt & Isle of Hope Railway Company, has tendered his resignation, to take effect July 1. Mr. Benagh will probably return to Nashville, Tenn., which city he left when he went to Savannah.

MR. PIERRE OTIS KEILHOLTZ, chief engineer of the United Railways & Electric Company, of Baltimore, will hereafter, in addition to the duties of his office, act as general manager of the United Electric Light & Power Company, of Baltimore.

MR. F. E. SMITH, auditor of the Lynn & Boston Railroad Company, has accepted a similar position with the Massachusetts Electric Company, which has effected a consolidation of the principal suburban electric railways of Eastern Massachusetts, and has entered upon his new duties.

MR. FRANKLIN WOODMAN, of Haverhill, Mass., has been appointed general manager of the Merrimac Valley division of the Massachusetts Electric Company. Mr. Woodman was formerly manager of the Haverhill division of the Lowell, Lawrence & Haverhill Street Railway Company.

MR. F. L. HART, formerly of Baltimore, has been appointed general superintendent of the system of street railways at Washington, D. C., recently purchased by a syndicate for the purpose of consolidation. Mr. Hart has been for some time engineer in charge of the re-equipment of the Anacostia road.

MR. HENRY VILLARD is preparing for a journey to Alaska, and will start about July 1. In the course of his trip he will celebrate the twenty-fifth anniversary of his first visit to Washington—a visit which has had enormous consequences to the people of the great Northwest and the Northern Pacific Coast.

MR. HARRY D. LIVERS, formerly connected with the Tamaqua & Lansford Electric Railway Company, of Tamaqua, Pa., on June 1 succeeded J. A. Bonnell as superintendent of the Carbon County Electric Railway Company, Mauch Chunk, Pa. Mr. Livers has recently arrived home from active service in the Spanish war.

MR. G. SACCO ALBANESE, a well-known engineer, both in America and Europe, and who has been engaged in the construction of a large number of electric railways in France and French colonies, has recently been honored by the French government with the decoration of an officer of the Academy of Arts and Sciences.

MR. HENRY C. MOORE, president of the Trenton Street Railway Company, has been appointed vice-president of the United Power & Transportation Company, which controls about fifteen street railway properties in Philadelphia and the surrounding country. Mr. Moore still retains the presidency of the Trenton road.

MR. ELWIN C. FOSTER, general manager of the Lynn & Boston Railroad Company, has been given largely increased responsibilities in connection with the new consolidated system of the Massachusetts Electric Company, and will be in charge of the entire North Shore section of the system, from Boston to the Merrimac Valley.

MR. FRANK G. LOTT, who has held the position for some time of superintendent and general manager of the Buffalo & Niagara Falls Electric Light & Power Company, has been appointed superintendent of the Lewiston & Youngstown Frontier Railroad Company, of Lewiston, N. Y. He takes the place of Mr. W. A. Heller, resigned.

MR. H. A. EVERETT has been elected president, Mr. Will Christy vice-president, Mr. J. R. Nutt treasurer, Mr. C. S. Moore secretary, and Mr. L. S. Beilstein general manager of the Northern Ohio Traction Company, which is a consolidation of the Akron Traction & Electric Company and the Akron, Bedford & Cleveland Railroad Company.

THE METROPOLITAN ELEVATED RAILROAD COMPANY, of Chicago, has elected a new board of directors, including Dickinson MacAllister, the president; W. W. Gurley, Byron L. Smith, George B. Harris, John P. Wilson and George Higginson, Jr., of Chicago, and C. F. Dieterich, R. S. Hays and James J. Higginson of New York.

MR. WILLIAM D. BUCKNER, assistant chief engineer of the Guayaquil & Quito Railroad (a steam road), of Ecuador, is in New York city. His visit to the United States is for the purpose of attending to some improvements for the road, making purchases of construction outfit and engaging engineers. His address is 49 West Thirty-first Street.

MR. ALLEN F. EDWARDS, who, for the past year, has been the general superintendent of the Yonkers Railroad Company, is now general manager of the Virginia Traction Company, of Petersburg, Va., and also general manager of the Electric Light Company, of the same place. These two companies have been purchased by the same syndicate, and will shortly be combined.

MR. PHILIP DAWSON, engineer with Messrs. Robert W. Blackwell & Co., of London, has been traveling in the West during this month, particularly in Chicago and Milwaukee. In Chicago he has been looking very carefully into the operation of elevated electric railroads, and in Milwaukee is inspecting some of the engines recently ordered by Mr. Blackwell on British contracts.

MR. HUGH J. McGOWAN has been elected vice-president and general manager of the Indianapolis Street Railway Company. Mr. J. Grant, formerly superintendent of the Citizens' Street Railway Company, Detroit, is assistant general manager. Mr. W. F. Milholland, formerly treasurer and assistant secretary, has been re-elected to the same position, and Mr. Miller Elliott re-elected as superintendent.

MR. F. S. PEARSON, chief engineer of the Metropolitan Street Railway Company of New York, sailed for Sao Paulo, Brazil, on June 5, in order to inspect the city and determine on certain general problems connected with the development of the street railway and lighting system of Sao Paulo, for which franchises have recently been obtained by himself and associates. He expects to return in August.

MR. R. C. BROWN, who has been for some years connected with the Whitney-Elkins-Widener syndicate as one of its most trusted engineers and street railway managers, sailed for Sao Paulo, Brazil, on June 5, in order to take charge of the construction, equipment and (temporarily) the operation of the large electric tramway and light enterprise which is being developed there by a New York and Canadian syndicate composed of F. S. Pearson, William McKenzie and others.

MR. F. P. BROTHERS, MR. NORMAN S. RANKIN and MR. SHIRLEY DAVIDSON, who have been for some time in Kingston, Jamaica, superintending the construction of the West India Electric Tramway of that city, have returned to Montreal, their native city, for a short vacation. These gentlemen report that the Kingston road has been practically completed as far as track construction is concerned, and the line will be in operation soon. It is about 30 miles long, and steel ties were used exclusively, owing to the climatic conditions and wood-boring insects.

MR. JOHN A. RIGG, president and general manager of the United Traction Company, of Reading Pa., has accepted the position of president of the United Power & Transportation Company, the formation of which is mentioned elsewhere in this issue. He has been a leading spirit in perfecting this consolidation, and its successful consummation is due largely to his energies. Mr. Rigg has been actively engaged in street railway work for over a quarter of a century, and has been prominent in the affairs of the American Street Railway Association, in which he has held various offices.

MR. F. H. CHEVALLIER BOUTELL, general manager of a large trust company of Buenos Aires, resident director of the Buenos Aires & Belgrano Tramway Company, of Argentina, and resident director for two important railroads and several industrial enterprises in Buenos Aires, in which London capital is interested to the extent altogether of $150,000,000, was in the United States for a brief pleasure trip, and returned to London on June 28,, and will reach Buenos Aires in August. He visited New York, Philadelphia, Washington, Chicago, Detroit, Niagara Falls, Schenectady and Boston, and derived a great deal of enjoyment from his first American experience. A report appeared in the Chicago papers soon after his visit to that city that he had placed an order for $5,000,000 worth of cars in that city, but this was wholly false. Mr. Bouteil also very carefully investigated American locomotives, his disposition being to purchase future supplies for his Argentina enterprises as largely as possible in America.

MR. O. T. CROSBY, through whose efforts, in combination with those of Mr. C. A. Lieb and F. C. Stevens, the general consolidation of street railway properties in the city of Washington has just been made, sailed for Europe recently, with Mrs. Crosby, to secure a much needed rest. He has given up official connection with all of the Washington properties in order to free himself completely for a prolonged pleasure-seeking and health-restoring trip. In 1895 Mr. Crosby went to Washington with Mr. Lieb, and the two bought a controlling interest in the Georgetown & Tenalleytown Railway. In the latter part of the same year they also secured control of the Potomac Power Company, then located on the Virginia side of the river, together with pole and wire privileges in the District. A little later the Potomac Light & Power Company was organized, and Mr. Crosby extended his railway and lighting interests until the consummation of the recent general consolidation.

MR. H. S. COOPER, who has recently resigned from the superintendency of the Schenectady Railway Company, of Schenectady, N. Y., was born in Isle of Wight, England, in 1856, and came to America in 1865. He was educated at Farnum School, Beverly, N. J., and worked as office boy, clerk and salesman in Philadelphia from 1870 to 1876. In 1876 he went into the manufacturing of agricultural machinery in the South, first at Raleigh, N. C., and again at Jacksonville, Fla., and in connection with this business had, during 1884 and 1885, the charge of the electrical work on two lines of steamers on the St. Johns River, and of much work on the two lighting stations then in Jacksonville. From this time until 1893 he had charge of numerous electric railway and lighting installations, and in that year, at the urgent solicitation of the owners, he accepted the managership of the Schenectady properties of the Electrical Development Company, these properties consisting of the entire electric and gas lighting and railway and motor business of the city. These properties were then in desperate shape, and the business depression of 1893 necessitated the placing of them in the hands of a receiver. The receiver was changed in 1894, and in 1895 the properties were sold under foreclosure of the bonds, and then reorganized. Since taking charge, in July, 1893, the properties have been entirely and absolutely under Mr. Cooper's management, and without outside aid of any kind—financial or otherwise—they have been developed from their own resources until they are now in fine physical condition and on an excellent paying basis, and have the good will and co-operation of the entire community, both private and municipal.

H. S. COOPER

AMONG THE MANUFACTURERS

THE GENERAL ELECTRIC COMPANY, of Schenectady, has published recent bulletins on grooved trolley wire, the G. E. 55 railway motor, and the C. E. motor.

THE AMERICAN IMPROVED RAIL JOINT COMPANY, of Chicago, has taken a contract to cast weld some 5000 joints in Indianapolis, and work on the same has already commenced.

THE FUEL ECONOMIZER COMPANY, of Matteawan, N. Y., after July 1 will be known as the Green Fuel Economizer Company. The new works are very busy, running to their full capacity.

THE CONSOLIDATED PUBLIC WORKS COMPANY, of Philadelphia, has acquired the business interests formerly owned by the Wheeler & Boody Company, the latter company having recently been dissolved by mutual consent.

J. G. SATTERTHWAIT, formerly with Walker & Kepler, is now connected with the C. & C. Electric Company, at its Philadelphia office. Mr. Satterthwait will be pleased to answer any inquiries regarding dynamos or motors, either direct connected or belted.

THE NORTH AMERICAN CONSTRUCTION COMPANY, of Chicago, which secured the contract for the deck work on the Northwestern Elevated, has commenced laying the material, and expects to have this finished within the next three months.

THE PITTSBURGH FEED WATER HEATER COMPANY, of Pittsburgh, Pa., has just issued a new illustrated catalogue of the Pittsburgh feed water heaters and purifiers, showing both the open and closed types manufactured by it. The cata-

logue is illustrated with numerous cuts, and a copy can be had by writing to James Bonar & Co., Pittsburgh, Pa.

THE COLUMBIA ELECTRICAL SUPPLY COMPANY, formerly at 329 Fourth Avenue, New York, has removed to 93 Liberty Street, where it has one of the handsomest arranged stores to be found in the electrical supply trade. The company carries a large stock of electrical goods, to which will gradually be added a line of street railway material.

THE MICA INSULATOR COMPANY, of Chicago, has received during the past month its usual large number of orders for its insulating materials, viz., micanite plates, segments, rings, etc., "Empire" insulating cloths and papers and M. I. C. compound. The company's business during the last two months shows a very heavy increase over the corresponding period of last year.

THE GARTON-DANIELS ELECTRIC COMPANY, of Keokuk, Ia., since Jan. 1, 1899, has shipped its arresters into every State of the Union, and has made over fifty shipments abroad. It also states that the sales of these devices from Jan. 1, 1899, to the present time are equal to the total sales of any preceding year. This is convincing proof of very high merit in these devices.

EDWARD ROBINSON, proprietor of the Wells Light, 44 and 46 Washington Street, New York, returned from England on the steamer Umbria a few days ago, after a very pleasant trip, taken partly in the interest of the Wells Light business and partly for pleasure. During his absence abroad 1500 of the now famous Wells Lights were sold to the Russian government for use upon the railroads in that country.

H. W. JOHNS MANUFACTURING COMPANY, of New York, will hereafter be represented in Chicago by the Manville Covering Company, with offices at 173 Randolph Street. H. A. Reeves, manager of the electrical department of the latter company, and long known in connection with the Chicago office of the H. W. Johns Company, will be in charge. He reports an immense demand for molded mica, vulcabeston, etc.

THE DORNER TRUCK & MANUFACTURING COMPANY, Cleveland, Ohio, has under way a new factory at Logansport, Ind., which will be fully equipped with all the modern machinery for turning out trucks and other street railway specialties, including the new friction brake recently brought out by this company, track cleaners, etc. The company reports quite a large number of orders for trucks, brakes and track cleaners.

THE ROBB ENGINEERING COMPANY, of Amherst, N. S., recently shipped, via New York and London, two 350-h.p. engines for the Perth Tramways Company, Perth, West Australia. These engines are tandem compound, side-crank type, and are for direct connection to General Electric 225-kw. dynamos. The order was placed through J. G. White & Co., of New York, who have the contract for the complete equipment of the tramway.

THE B. F. STURTEVANT COMPANY, of Boston, Mass., has adopted a somewhat unique method of proving the claims made for the Sturtevant system of ventilation and heating. This consists of an artistic pamphlet containing some fifty-three pages, and devoted exclusively to a list of buildings and steamships wherein the system has been installed. About 2500 names are given, and the list contains some of the very best plants in the country.

THE E. W. BLISS COMPANY, of Brooklyn, N. Y., manufacturers of presses, dies, shears and special machinery for all classes of sheet metal work, is sending out a neat pocket-size pamphlet containing small cuts and a brief, yet comprehensive description of many of its more important machines. The company carries in stock a complete line of standard tools, and makes a specialty of designing and manufacturing machinery for special purposes.

THE WESTINGHOUSE MACHINE COMPANY, of Pittsburgh, Pa., is calling attention to the Westinghouse Junior engine through a tasteful catalogue just issued. This engine is equal in every detail of workmanship and material to the regular Westinghouse standard engines, but is built in small sizes only. It is of the simple single valve automatic type, and its economy of operation, together with its comparatively low first cost, makes it a very desirable machine for a small plant.

THE PITTSBURGH FEED WATER HEATER COMPANY, of Pittsburgh, Pa., has published a new catalogue, setting forth the economy and efficiency of the different types of feed water heaters and purifiers which it manufactures. These devices have been considerably improved since first placed upon the market, and the manufacturers now claim they have the most efficient, simplest and most economical heater in the market, citing a number of features substantiating this claim.

J. G. WHITE & CO., of New York, are designing and supervising the erection of a brick power house, complete, for the Detroit & Lake Orion Railway Company, and are furnishing and erecting two 250-h.p. Cahall boilers, two 300-h.p. Ball & Wood engines, two 200-kw. Crocker-Wheeler railway generators, direct connected, one 60-kw. Crocker-Wheeler booster, together with chimney, piping, condensers, feeders, pumps, switches, wiring and all accessories; also one 90-kw. lighting generator.

THE H. C. ROBERTS ELECTRICAL SUPPLY COMPANY, of Philadelphia, reports a steady increase in the demand for its products, among the recent sales of trolley and feeder wire being large quantities to the interurban electric railway from Dayton to Xenia, Ohio, the Schuylkill Valley Electric Railway Company, of Pottsville, Pa., and the Norfolk Terminal Company, Norfolk, Va. The company's wire has also been shipped to Lewiston, Pa., Cincinnati, Ohio, Rising Sun, Ind., and numerous other places.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY, of Pittsburgh, Pa., has issued the following catalogues: No. 110-E, devoted to transformer fuse blocks of 1000 to 300 volts capacity; No. 188-B, describing the Westinghouse No. 38-B single reduction railway motor; No. 229, describing belt-driven railway generators; No. 200-A, describing generators and rotary converters for electrolytic work; No. 168-C, describing the Shallenberger integrating wattmeters for alternating circuits.

THE CHICAGO OFFICE of the Westinghouse Electric & Manufacturing Company has received a contract from the Muskegon Street Railway Company, of Muskegon, Mich., for an addition to the latter's electrical plant. This consists of a 275-h.p. belted generator, to be driven by a steam engine, and also an elaborate switchboard for regulating and manipulating the electrical current. This new generator will be worked in connection with those previously installed, and will supply power for the cars running upon the newly extended lines of the street railway company.

THE TURNER ENGINEERING COMPANY, of Bucyrus, Ohio, will erect at once a complete boiler plant for the Marion Steam Shovel Company, including a large self-supporting steel chimney, brick lined, after special designs. This latter company sends its shovels and dredging machinery to all parts of the world, and maintains its plant strictly up to date, with the most modernly improved money and labor saving devices. After careful and exhaustive consideration of all water tube boilers, the management decided to use the Turner boilers as possessing the greatest general merit and economy.

THE B. F. STURTEVANT COMPANY, of Boston, Mass., early recognized the demand for electrically driven fans which was sure to follow the general distribution of electricity for power purposes. Its first fan motors were built about ten years ago, since which time designs have been perfected, the number of types greatly increased, and a large electrical department established. Some of the recent products of this company in the way of special electric fans are presented in its bulletins H and M. The former relates to the inclosed fans, the latter to propeller ventilating wheels.

THE CHRISTENSEN ENGINEERING COMPANY, of Milwaukee, Wis., as an adjunct to its regular line of air brakes for street railway purposes, is also engaged in the manufacture of a complete line of air compressing appliances, including portable compressors, air hoists, air jacks, etc. The value of compressed air for performing a variety of work is rapidly coming to be recognized in a number of industries, and the demand for a simple and effective compressing apparatus is continually increasing. The Christensen portable air compressor was described in the last issue of the Street Railway Journal.

THE FALK COMPANY, of Milwaukee, Wis., recently lost by fire its complete blacksmith and special work shops. Shortly after the fire, however, the company had made arrangements for continuing the manufacture of its special work. The Falk Company has in process of erection several extensions to its plant at Milwaukee, and expects to be in a position within a short time to again take care of all orders. Eight acres of ground close to the present shops have been purchased, and new buildings will be erected thereon. These will consist of a machine shop, 100 ft. x 200 ft.; a foundry equipped for casting steel, also 100 ft. x 200 ft.; a power house, 60 ft. x 40 ft., and an office building, 40 ft. x 60 ft.

THE WAGENHALS MANUFACTURING COMPANY, Cincinnati, Ohio, reports that its new controller handle, which was described in the STREET RAILWAY JOURNAL for May, 1899, is creating considerable interest among street railway managers, and that its value as a current saver is coming to be recognized. These handles are now in use on the Union Traction Company's line, of Philadelphia; Cincinnati Street Railway, Cincinnati, Ohio; Detroit & Pontiac Railway, Detroit, Mich.; Syracuse & Suburban Railway Company, Syracuse, N. Y.; Camden & Suburban Street Railway Company, Camden, N. J., and several of the St. Louis lines. Orders have also been received from the Cape Town Tramways, Cape Town, South Africa.

THE TRADE PAPER ADVERTISING AGENCY, of New York, is sending out a unique and very artistic brochure, containing a number of original designs for advertising purposes, which were drawn by the special artist of the Trade Paper Advertising Agency. These are extremely striking, and many of them have appeared in the leading technical papers of the United States. This concern is prepared to take charge of the advertising of any reputable house, however large, and will attend carefully to all the details, thus giving the manufacturer the benefit of an expert knowledge of the design and arrangement of advertisements. Edward Caldwell, who was at one time business manager of the STREET RAILWAY JOURNAL, is manager of this advertising agency.

THE HOPPES MANUFACTURING COMPANY, of Springfield, Ohio, reports repeat orders from the following well-known firms: The Kelly Axe Manufacturing Company, Alexandria, Ind., 400-h.p. live steam feed water purifier and 400-h.p. exhaust steam feed water heater; the Deering Harvester Company, Chicago, Ill., two 1250-h.p. purifiers; Louisville Railway Company, Louisville, Ky., three 625-h.p. purifiers; E. L. McClain Manufacturing Company, Greenfield, Ohio, 400-h.p. purifier and 350-h.p. heater; Danville Gas, Electric Light & Street Railway Company, Danville, Ill., 1000-h.p. purifier; South Dakota Hospital, Yankton, S. D., 200-h.p. purifier, 400-h.p. exhaust steam feed water heater; Jeffrey Manufacturing Company, Columbus, Ohio, 500-h.p. purifier and 500-h.p. heater.

THE BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., has received during the past few weeks a contract for building several new plants of considerable importance. Among these are the extensions to the plant of the Wheeler & Wilson Manufacturing Company, a warehouse building at Dutch Guiana, and a new furnace building at Perth Amboy, N. J., for the Raritan Copper Company. Among the foreign orders is one from the Council of Rangitikei County, New Zealand, for a highway bridge consisting of a single span of 204 ft., designed to carry a distributed load of 1500 lbs. per lineal foot. In transmitting this order the chairman of the Council said, "As far as I know, this is the first order of the kind ever sent to the United States, and the experiment is being watched by other local boards."

THE ELECTRIC STORAGE BATTERY COMPANY, of Philadelphia, on June 14, in the United States Circuit Court, at Boston, Mass., secured a preliminary injunction against the Quincy & Boston Street Railway Company, restraining the latter from using and operating the elements of the Hatch storage battery installed at South Braintree, Mass., and used as an auxiliary to the trolley system. It is held that the Hatch battery infringes upon the Brush patents owned by the Electric Storage Battery Company, and which are fundamental patents underlying all forms of storage battery. This injunction becomes effective on August 1, as the railway company was given until that time to remove the infringing batteries. This is only one of four or more suits which are the outgrowth of that in which a preliminary injunction was granted against the Hatch Battery Company on May 5 last.

THE CREAGHEAD ENGINEERING COMPANY, of Cincinnati, is sending out a new catalogue, which will be found unusually complete. It describes the company's electric railway overhead line material and electrical supplies, and should be in the hands of every railway general manager. In addition to the well-known Creaghead type of insulators, mechanical ears, and other overhead supplies, all of which are fully illustrated in the catalogue, are notices and full descriptions of the Creaghead flexible and rigid brackets, trolley harps, wheels and poles, protected rail bonds, Garton lightning arresters, Weston electrical instruments, cut outs and switches, construction tools, and enclosed arc lamps. The company calls particular attention to the fact that the excellence of all its materials is the result of several years' experience in the construction of electric railways, and the devices described in the catalogue have been thoroughly tested. The catalogue will be sent on request.

HARRISON SAFETY BOILER WORKS, of Philadelphia, Pa., report the following recent sales of the Cochrane feed water heaters and purifiers: Haverhill (Mass.) Electric Company, 1000 h.p.; Alabama Steel & Wire Company, Ensley, Ala., 6000 h.p.; Ohio Steel Company, Youngstown, Ohio, 10,000 h.p.; Hoopes & Townsend, Philadelphia, 1000 h.p.; Barrett Manufacturing Company, Philadelphia, 450 h.p. special; American Steel Foundry Company, St. Louis, Mo., 850 h.p.; Telephone & Improvement Company, Sweetwater, Tenn., 100 h.p.; Detroit Reduction Company, Cripple Creek, Colo., 425 h.p.; E. Sutro & Son, Philadelphia, 150 h.p. special; Barnard & Leas Manufacturing Company, Moline, Ill., 100 h.p.; Dickson Manufacturing Company, Scranton, Pa., 200 h.p.; Mound Coffin Company, St. Louis, Mo., 200 h.p.; Munger Oil & Cotton Company, Mexia, Texas, 250 h.p.; Cocheco Manufacturing Company, Dover, N. H., two 250 h.p.; Vulcanite (N. J.) Portland Cement Company, 1000 h.p.; also the following recent sales of the Cochrane separators: Law Building, Chicago, Ill., two 5-in. vert.; James Clements & Son, Bay City, Mich., 8-in. and 3½-in.; Franklin Mining Company, Hancock, Mich., 14-in. and 6-in.; Carnegie Steel Company, Pittsburgh, three 16-in. and one 10-in.; Laughlin & Co., Ltd., Pittsburgh, six 5-in., five 10-in., one 7-in., one 4-in., two 6-in. and two 12-in.; Cambria Steel Company, Johnstown, Pa., two 12-in.; Cedar Rapids (Ia.) Electric Light & Power Company, 12-in.; Cunard Steamship Company, New York, 4-in. and 4½-in.; Haverhill (Mass.) Electric Company, 7-in.; American Blower Company, London, England, 4-in., and many others.

New Publications

Soft Coal Burning. By C. M. Higginson. Paper. 18 pages. Illustrated. Published by the "Railway Master Mechanic," Chicago.

This is the fifth edition of this pamphlet, and is a valuable treatise on the subject of soft coal, giving the relative economy of this fuel, and describing the best methods of burning it.

Verbatim Report of the Seventh Annual Meeting of the Pennsylvania Street Railway Association. Paper. 67 pages. Published by the association.

This is the report of the meeting held at Scranton, Pa., Oct. 19 to 20, 1898, and contains the papers read, the discussions upon same, the speeches at the banquet, copy of the constitution, and a list of the active members.

The Influence of Mechanical Draft Upon the Ultimate Efficiency of Steam Boilers. By Walter B. Snow. Paper. 22 pages. Illustrated. Reprinted from the "Columbian Engineer," of Columbia University, New York.

This is a lecture delivered by Mr. Snow, of the engineering staff of the B. F. Sturtevant Company, of Boston, before the Engineering Society, on Dec. 1, 1898. An abstract of the lecture will be found in the last issue of the STREET RAILWAY JOURNAL.

Duncan's Manual of Tramways, Omnibuses and Electric Railways. Cloth. 428 pages. Price, 3s. 6d. Published by T. G. Whiting & Sons, Ltd., London, England.

This is the twenty-second annual issue of Duncan's Manual, which has now come to be the recognized authority on financial statistics concerning the tramways of England and in the colonies which are owned by London capitalists. The manual is similar in typographical features to issues of previous years.

Derrah's Street Railway Guide. Compiled by Robert H. Derrah, of Boston. Paper. 210 pages. Illustrated. Price, 15 cents. Published by the compiler.

This is the fourth edition of this guide, and contains complete time tables, together with full information of all the street railway lines in Eastern Massachusetts. Everything that the tourist in this section might require is included in the book. A large inset map of the region covered is one of the features.

The Steam Engine Indicator (compiled from the regular issues of "Power"). Cloth, 208 pages. Illustrated. Price, $1.50. Published by the Power Publishing Company, New York.

Although there are a number of books on the construction and use of the indicator, we know of none which takes up the subject in a clearer or more systematic way than that whose title is given above. The valuable lessons on engine design and regulation which the indicator can teach are carefully explained, as well as the methods of computing the area of the diagram, mean effective pressure, steam consumption, etc. The book is fully illustrated.

L'Electricité en Amérique. By Marcel Delmas. Paper. 81 pages. Reprinted from "Le Genie Civil," Paris.

This pamphlet contains some notes on the application of electricity to industrial and railway purposes, gathered by M. Delmas during a recent visit to this country. The first chapter is devoted to electric traction, the installations described being the elevated roads of Chicago and (briefly) the surface systems of New York, Chicago, Buffalo and Boston, with an extended description of the subway in the latter city. M. Delmas attributes a large amount of the rapid development of industrial enterprises in this country (1) to the wider field that American engineers and manufacturers have as compared to any single country in Europe; (2) to the comparative freedom enjoyed from governmental restrictions; (3) to the greater absence of "red tape" in the conduct of their own affairs, and (4) to the quality of building apparatus and turning out work quickly, even if this sometimes involves a sacrifice of some minor economies.

The Commercial and Business Aspects of Municipal Electricity Supply. By Alfred H. Gibbings, Electrical Engineer to the City of Bradford, England. 270 pages. Illustrated. Price, 15s. Published by the author.

This book discusses many problems which arise in the commercial aspects of supplying electricity from central stations for lighting and power, and the means preferred by the author for dealing with them. They include methods of charging for electrical energy, the renting out of motors, whether lamps should be supplied by the company or by the user, street lighting, etc. Some very valuable tables are also given, showing the average amount of power required by the users of motors in small industries, of light, etc. Mr. Gibbings also gives a number of forms used by him in keeping his records, making charges, etc. The book should be extremely valuable to station managers on both sides of the water.

Municipal Monopolies. A collection of papers by modern economists and specialists. Edited by Edward W. Bemis, Ph. D., Professor of Economic Science in the Kansas State Agricultural College. Cloth. 691 pages. Price, $2. Published by Thomas Y. Crowell & Company, New York.

This recently issued book comprises a number of very interesting monographs on different kinds of municipal service enterprises, which are discussed by writers who are in more or less pronounced sympathy with an extension of municipal ownership over city monopolies, but the attempt has been made to treat the whole problem broadly and in full recognition of the difficulties involved in any suggested solution, and the result is the collection of a mass of information which is extremely valuable to the student of social economics. The subject of "Waterworks" is treated by M. N. Baker, of the "Engineering News;" "Municipal Electric Lighting," by Prof. John R. Commons, of Syracuse University; Prof. F. A. C. Perrine, of the engineering department of Leland Stanford University, and by Prof. Bemis; Max West, Ph. D., of the agricultural department at Washington, describes "Municipal Franchises in New York;" Prof. Frank Parsons, of the Boston School of Law and the Kansas State Agricultural College, treats of "The Telephone" and the "Legal Aspects of Monopoly," and Prof. Bemis discusses "Street Railways" and the problem of "Regulation of Ownership." The book is well worth to street railway and electric lighting managers its very moderate price, if only to obtain the point of view of the municipal ownership advocates.

Regelung der Motoren elektrischer Bahnen. By Dr. Gustav Rasch. Cloth. 140 pp. Illustrated. Price 8 marks. Published by Julius Springer, Berlin.

The "Control of Electric Car Motors" is the title of a new work by Dr. Gustav Rasch, of the Technische Hochschule of Karlsruhe, which forms the first volume of a series on electric railroads, and is the outcome of a course of lectures given by the author. This probably accounts for the fact that the subject is treated in a manner making the book suitable for a text-book, while its numerous mathematical demonstrations, including the use of calculus, will probably forbid its practical and universal introduction among the laymen. The book is thorough in its scope, and contains much valuable matter, which has to be dug out, however, and even after this is done the reader finds references to mathematics in the author's conclusions. The book is divided into eight chapters, dealing respectively with the following subjects: In Chapter I. the author discusses the various train resistances on straight and curved tracks, evolves formulæ for energy consumed on grades and returned on declines, acceleration, and shows how to determine the coefficient of traction. In Chapter II., the well-known e.m.f. and counter e.m.f. formulæ are attained, the various kinds of armature windings are discussed, as well as the questions of efficiency, losses, torque, effort at rim of wheel, the relative advantages and disadvantages of series and shunt motors at starting, speed and load. A general discourse on methods of control is given in Chapter III., and the author proceeds by first enumerating the various methods by which the speed may be altered, viz.: (1) by changing the counter e.m.f., and (2) by varying the magnetic field. The first-named presents two conditions, namely: a constant e.m.f. at the terminals of the motor, and an e.m.f. which may be varied, as in the case of accumulators. The constant e.m.f. can be varied by an external resistance or by connecting the motors together in various ways. The magnetic field may be changed by introducing a shunt resistance to the field, or by splitting up the field coils and connecting the sections to suit conditions. The author presents these various methods in a sort of "family tree fashion," which is highly commendable. In Chapter IV., the method of introducing an external resistance is discussed by curves, diagrams and formulæ. The author contends that the method is not applicable for varying the speed of motors employed for normal service, but is useful when the tractive effort and speed are not widely varying quantities. He further states that if one motor can exert the necessary effort it would be poor economy to subdivide that effort among two motors connected in parallel, unless a rise in speed is desired. As an example of this method, the Schuckert system is cited. Chapter V. is devoted to a discussion of the series-parallel method of control, showing the effect of one-half the e.m.f. on the speed, the starting torque and the use of four motors. He points out that the method is not practical when two motors are used, unless a resistance is inserted to aid in the control, as is the case in the Walker controller, which is described. In comparing this method with the one described in Chapter IV., the author states that the series-parallel method, permitting a great variation of speed, is applicable for city, city and suburban and suburban service, while the resistance method is only permissible for the first named. He devotes no space to accumulator traction, as the number of accumulator roads is continually on the decrease. The method of shunting the field coils is treated in Chapter VI., and this, the author states, permits a simpler controller construction than the series-parallel method. The former method, however, is only applicable where the traffic conditions are uniform or vary between very small limits, that is, for city or suburban service, and not for the combined. In Chapter VII. the method of connecting field sections in various ways is discussed, which simply implies a variation of the ampere turns in the field. This method is preferable to the shunt resistance method, where high speeds are employed, but the advantages of the one and the disadvantages of the other about balance each other. Electric braking forms the subject of the eighth and last chapter, and the author contends that for braking purposes series motors can be used as well as shunt motors. If, however, it is desired to win back some of the energy, the series motor cannot be employed, whereupon he discusses the question of winnig back the energy. This introduces the question of storage batteries where the method of electric braking has a distinct advantage. The author reaches the conclusion, however, that the advantages of returned energy are very frequently overrated.

Trade Catalogues

Advertising Designs. Published by the Trade Paper Advertising Agency, of New York.

Bulletins. Published by the General Electric Company, of Schenectady.

Street Railway Journal

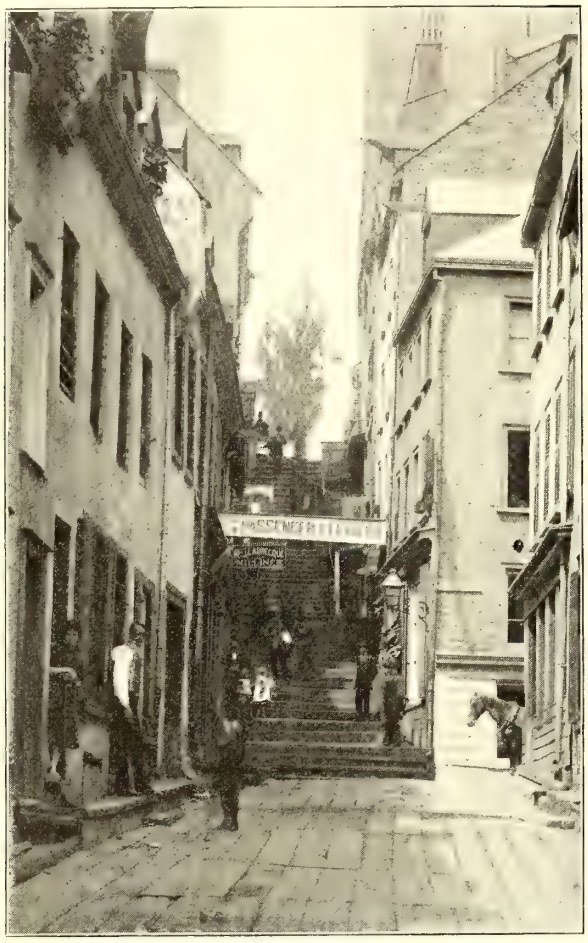
VOL. XV. NEW YORK AND CHICAGO, AUGUST, 1899. No. 8.

THE ELECTRIC RAILWAY SYSTEMS OF QUEBEC, CANADA

On July 1, 1899, the Quebec District Railway, or, as it is now known, the Q., M. & C. Railway, meaning the Quebec, Montmorency & Charlesvoix Railway, successfully completed its second year of operation, notwithstanding the many and varied difficulties, perhaps greater and more serious in their nature than usually confront a street railway company.

The first of these difficuties is the hilly—indeed, one might almost say mountainous—nature of the city. To those who have not had the pleasure of viewing this quaint

VIEW OF LOWER TOWN, QUEBEC



battleground where French power made its final and unold city, rich in olden time relics, with its population of French Canadians, its grand citadel and the old wall of fortification encircling the Upper Town, extending along the very brow of the hill, it will be difficult to fully comprehend the nature of the exacting conditions under which an electric railway is operated in this city.

The Upper Town has grown, expanded and pushed out beyond the fortifications, the new portion being principally residential. Here are the famous Plains of Abraham, the successful stand for the disputed possession of Canada. The Lower Town, situated at the water's edge, lying around the base of the hill—indeed precipice in many places—is perfectly level, and is the chief business district. The Upper Town, on the other hand, possesses many grades, the maximum track elevation above the Lower Town being 320 ft., which must be reached in one way or another.

To overcome the difficulties presented by these hills several methods are adopted, it being obviously impossible to ascend directly even for a horse slightly loaded. One street, Cote St. Abraham, ascends the hill obliquely, and though very steep is yet feasible, and here is located one cross-town route; a profile of the grades encountered is given on page 498. On this hill the heaviest grade is at Crown Street, one of 14.15 per cent—the heaviest traversed by the cars in Quebec—with, moreover, a 40-ft. radius curve at the top, half of it being on the grade.

It was necessary, however, to provide another cross-town route at the other end of the city, but here it was im-

possible to ascend the streets. After much thought had been devoted to the subject, a trestle, a side elevation of which is given, was finally adopted—the alternative being an elevator to raise or lower the loaded car—and constructed in a convenient location. This trestle ascends the first portion of the hill obliquely with a grade of 7 per cent. On reaching a certain point, where the trestle meets one of the cross streets, a curve was located on a level section on the trestle, after which the grade is 11 per cent for 300 ft., then 4 per cent till the Upper Town is finally reached.

TYPICAL STREET IN THE OLD QUARTER OF QUEBEC

The second hindrance, and a most important one in Northern countries, is the handling of the snow, which falls very heavily in these regions. Snow of itself is bad enough, but snow and hills combined are enough to dishearten the most optimistic of managers. Nevertheless, the regular runs are performed with, perhaps, much shorter intervals of stoppage than in larger cities further south, where they are unprepared to cope with such a difficulty. For instance, the snow fall last winter was 120.6 ins., the largest on record, and of this 44.6 ins. fell in March alone, yet there was no interruption in the regular service. This record was achieved by the diligent and continued use of sweepers, levelling plows and numerous box sleighs. Though there are but 18 miles of track, six snow sweepers are ever ready for operation.

When a snow storm occurs in the daytime the load upon the sweeper motors is very much greater than during night storms, for to prevent interference with the regular service it is necessary to run the sweepers in the same direction as the cars; that is, up hill on one track of a double-track road. On the other hand, during a night storm it is the practice for the sweepers to sweep down one track, return the same way, and then clear the remaining track also down grade. Meantime, levellers drawn by horses are also at work throwing the snow still farther from the track, whence it is removed in box sleighs.

The total equipment for the disposal of snow consists of six sweepers, each equipped with two standard 12 A 30-h.p. Westinghouse motors for traction purposes, and another motor of the same type placed in the cab for revolving the brooms, several horse-drawn levellers and numerous box sleighs. No 12 B. & S. copper wire is used as a fuse on the sweepers' motors, and will not blow before 230 amps. are drawn by the two traction motors.

CAR SERVICE

There are two principal routes, one in the Lower and one in the Upper Town; the schedule running time on both is at the rate of 8 miles an hour, and the average car mileage per day 106 miles; the headway on the principal streets is five minutes. Besides these two routes, there are two cross-town lines on which free transfers are issued from the main lines. Open cars are not used on these cross-town lines, on account of the excessive current required by the motors in ascending the heavy grades with ordinary loads and the greater danger of open cars becoming overcrowded. In ascending all heavy grades the motors are run in parallel, and in most cases momentum is secured before entering the grade, to aid the ascent, but on one grade of 11 per cent at the summit of the trestle previously mentioned power is shut off to pass around the curve at the foot of the grade. Extreme caution is exercised in descending heavy grades, the speed not being permitted to exceed 4 miles an hour, an ordinary walking pace.

In a city such as Quebec the braking system should be of special interest, yet nothing but ordinary brake shoes, the average life of which is three months, are used. These shoes are made of a specially soft cast iron, with the flanges perforated to permit the mud to percolate freely, and are supplied with a brake leverage of 10 to 1. Under these conditions it may be not a little surprising to find that skidding is very uncommon; in fact, the average number of wheels worn flat is only 14 per cent out of the total num-

CITY GATE

ber of worn out wheels, and these are mostly due to a slippery track in winter.

The wheels are 33 ins. in diameter, with a 4-in. axle, weigh 425 lbs. each, and are manufactured at the Rochester Car Wheel Works; the average life is 24,834 miles, including those worn flat, though no less than six pair have reached as high as 49,720 miles. Of the total number of wheels removed since July 20, 1897, 56.5 per cent were worn out; 15.55 per cent were worn flat, due to skidding; 4.44 per cent were replaced, due to chipping flanges, and 3.33 per cent were loose on the axle. One detriment to the life of the wheels on the Lower Town route is a certain quality of mud or grit which collects on the brake shoes, and there cakes to such extreme hardness that it is only possible to remove it with a cold chisel. This not only shortens the life of the wheels, but renders braking very difficult.

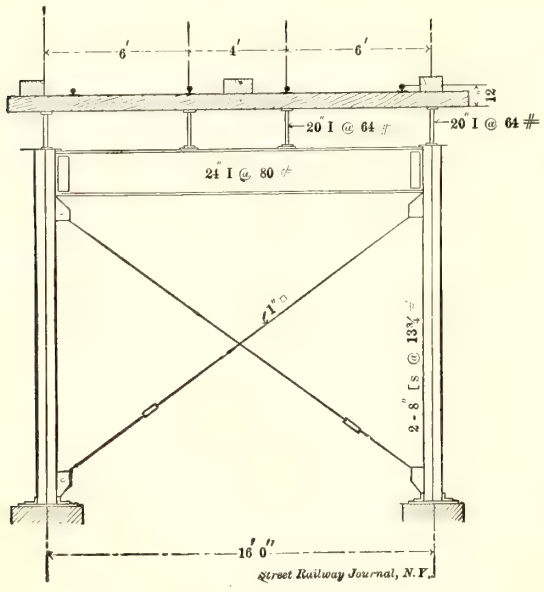
The summer service consists of forty-four cars per day, and the winter service of twenty-five cars per day.

ROLLING STOCK AND EQUIPMENT

The rolling stock consists of thirty-eight closed and twenty-four open cars and the six sweepers previously mentioned, the closed cars, of course, performing the greater service. These standard closed cars are very solid in their construction, and were built by the Ottawa Car Company, of Ottawa, Ont. The car body measures 18 ft. in length, with closed vestibules at each end and double sliding doors. The length over all is 28 ft. Each is capable of seating thirty passengers, and weighs fully equipped 7½ tons. The interior is very attractive, being finished in natural cherry, with birds-eye maple ceilings, and is brilliantly lighted by three clusters of four lamps each, set in brass fixtures. Each car is furnished with two electric reflector headlights, one at each end. The temperature of the interior is maintained uniform at 55 degs. F., or thereabouts, even in the coldest weather, by means of four electric heaters located under the seats, each consuming 1.1 kw. per hour.

The open cars are of the same dimensions as the closed cars, but have a seating capacity of fifty, and weigh 8 tons each, fully equipped, the average weight being 16,700 lbs. from an actual test. The bodies and side posts are of seasoned oak, with ceilings of birds-eye maple, and all handles and fixtures are solid brass.

Fares are collected from each passenger by a Coleman fare box. Sterling registers are also used. All car bodies are mounted on standard Taylor double side-braced trucks, having a 7-ft. wheel base.

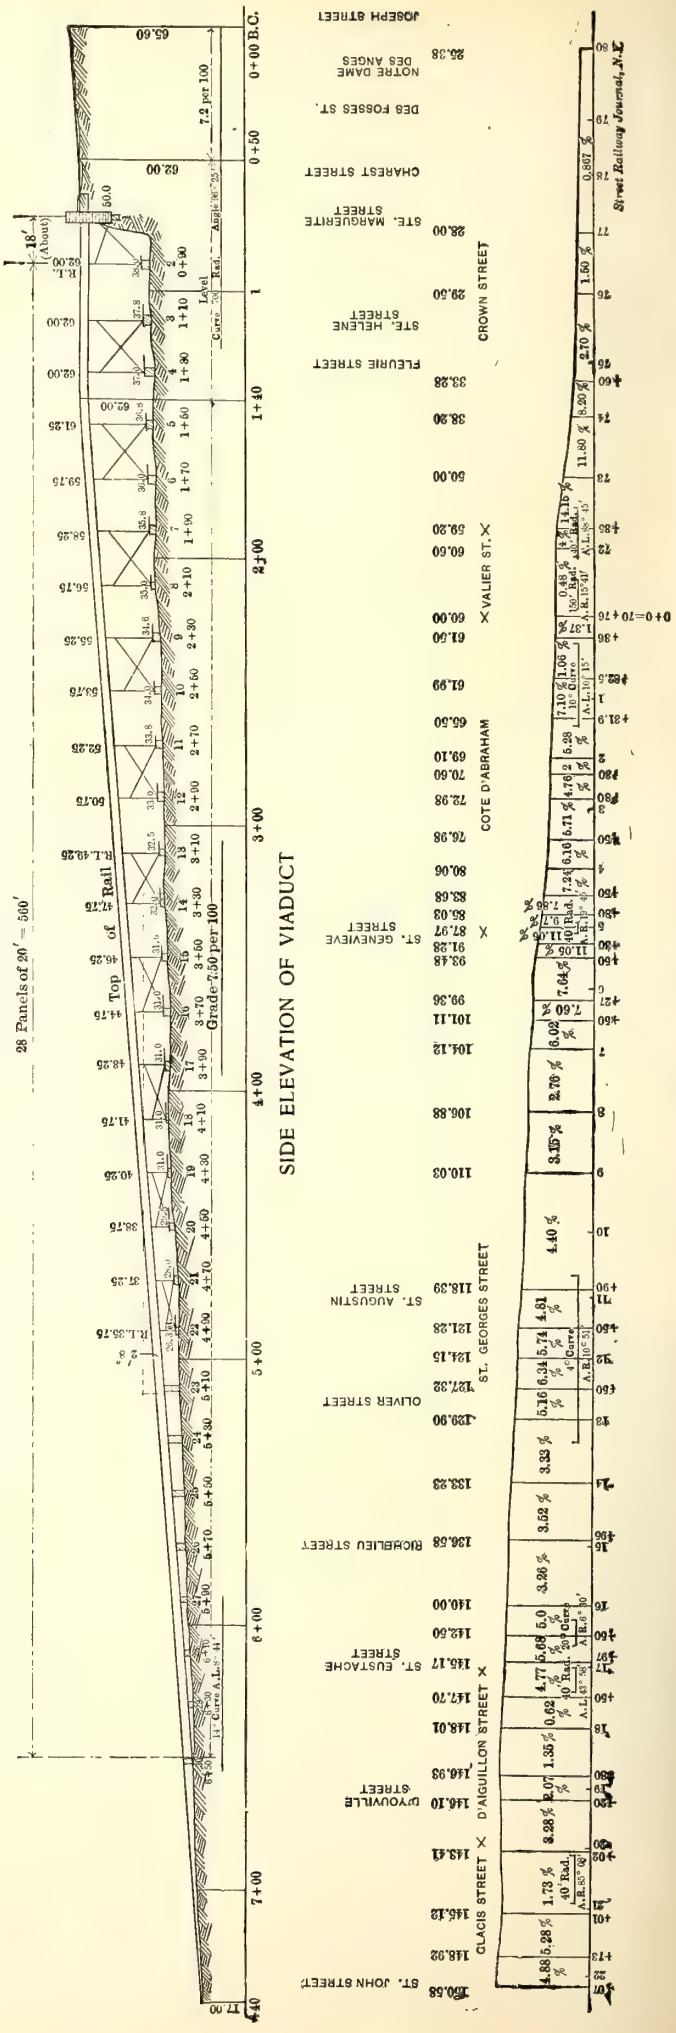


The motor equipment is Westinghouse throughout, and was supplied through Ahearn & Soper, of Ottawa. Two 12 A 30-h.p. motors are used on each car, and are regulated by series parallel controllers of the 28 A type. The gear ratio is 4.85. The fuse is No. 14 B. & S. copper wire, which will carry 175 amps. for a short time, such as may be required in ascending one of those short, steep grades so common in Quebec, or 150 amps. indefinitely in the winter.

MAP OF QUEBEC, SHOWING ELECTRIC RAILWAY SYSTEM

During the winter months the open car motors are transferred to the sweepers, which, as stated, require three each—two for driving the car and the other in the cab for operating the brooms, to which it is connected by chain gearing. No. 12 B. & S. copper wire is used as a fuse in all sweepers, being capable of carrying 230 amps for a short time without blowing, which amount is sometimes required in winter during a big storm. The total motor equipment consists of sixty-two double sets of motors and controllers.

A test was made recently to ascertain the current consumption in ascending the heaviest grade—one of 14.15 per cent, 90 ft. long, with a 40-ft radius curve at the summit, half of which is on the hill. It is customary to throw the power completely off the moment the car enters the curve, and as the car commences to lose momentum the power is thrown on again. Under the most favorable summer conditions the maximum current drawn by the two motors during the ascent until the curve was reached was 65 amps. at 520 volts, then after being turned off on reaching the curve and again thrown on the maximum reading was 130 amps., still at 520 volts. The average



SECTION OF VIADUCT

speed of the car was 4.5 miles per hour, and the estimated weight 9 tons. Under average winter conditions the current consumption rises to nearly 100 amps. on the grade, and to about 195 amps. on rounding the curve.

In descending all heavy grades the motormen are obliged to come to a standstill at the top to ascertain if the brakes are in good working order, after which the speed down grade must not exceed 4 miles per hour, so that a stop may be made, if necessary, on the hill. As all excessively steep grades are short, the time lost in going slow is very small.

The average power consumed in summer, as obtained by the integrating wattmeter in the station, is 8.3 kw. per car per hour, the average for the whole year being about 9.5 kw. per car per hour. The average mileage per car per day is 106.

The trolley wheel is of soft brass, $4\frac{1}{4}$ ins. in diameter, and as it is carefully greased every day it seldom leaves the trolley. Its average life is 10,000 miles, or about 95 days. Commutators run 25,000 miles before being sent to the lathe. The greatest wear on the commutator has been a decrease of 3-16 ins. in the diameter, the average has been $\frac{1}{8}$ in. The brushes used are of the Le Valley Vitae manufacture.

ROADBED

Double tracks are used in all streets wide enough to permit them. The roadbed is of the standard construction, with ties on well tamped beds 2 ft. between centers. During the process of laying asphalt pavements, since the inception of the street railway, concrete has been thoroughly tamped around the ties, and the usual method of placing paving blocks inside and outside the rails has been adopted. English T-rails, weighing 72 lbs per yard in 32-ft. lengths, are used almost exclusively. They are double bonded at each joint with two No. 00 copper wires, and cross bonded every fifth rail. The ends of the bond wires are tinned and are connected to the rails by Eclipse bonding caps, supplied by the Ohio Brass Company. Four ground returns, of 500,000 c.m. each, run on poles from the station. Three of these are connected to the nearest heavy traffic rails, a short distance away; the remaining wire is connected into the Upper Town rails. The object of the latter is to reduce the drop in the rails, as there are only two single-track lines connecting the Upper and Lower Town lines.

The following is a list of the longest grades over 8 per cent, over which the cars operate.

Ninety feet of 14.15 per cent, with a 40-ft. radius curve at the top, half on the hill;

Three hundred feet of 11 per cent (on trestle), with a curve of 70 ft. radius at the bottom;

Seventy-five feet of 9.7 per cent, with curves at top and bottom, and

Three hundred feet of 8 per cent, on which there is a 40-ft radius curve, connecting with 400 ft. of 4 per cent grade.

In two separate portions of the city reverse curves are required. Of these one has a 40-ft. radius on the entrance curve, but the reverse curve has a 34-ft. radius. This was necessary to round a shorp corner into a very narrow street.

SWEEPER AND TOWER WAGON

ENTRANCE TO CAR HOUSE

OVERHEAD CONSTRUCTION

Tubular poles, 28 ft. long, and weighing 700 lbs., and spaced 90 ft. apart, are used throughout. The overhead appliances are of the "Dirigo" type, and the trolley wire is No. 00. Four feeders, each of 500,000 c.m., run from the station, which is approximately in the electrical center of distribution. Lightning arresters of the Wurts non-arcing railway type are situated on the poles wherever the feeders tap the trolley.

At one point, where the railway crosses a drawbridge spanning the St. Charles River, which is navigable for small ships, it became necessary to place the feeder either under the river or at such a height that it would clear the masts of all passing ships. The latter course was adopted,

STANDARD CLOSED CAR

CURVE AT TOP OF AN 11 PER CENT GRADE

and two poles, each 150 ft. high, were placed on each bank, the feeder crossing on top. Each pole is built up of two separate pieces spliced together and the whole well guyed. For the ground return here a No. 0000 bare copper wire crosses the river on the bottom, and is connected to the bridge rails and to the rails on the opposite side of the river.

CAR HOUSES, REPAIRS, ETC.

There are two car houses. The main car house, which is the one illustrated, is a one-story brick structure 210 ft. wide x 120 ft. long, contains fourteen tracks, and has a capacity of fifty cars. There are seven pits, with the usual hydraulic jacks, etc., for motor handling. Opening out from the pits is a machine shop where motors may be repaired, and in which all the machine work in connection with the road and equipment repairs is performed. Situated under the car shed are the storerooms, blacksmith shop and oil room. This latter is a fireproof vault. On the ground floor are the superintendent's and engineer's offices and the employees' room, where orders are given, and where an employee may come and spend a sociable evening.

The remaining car shed is also of brick, and is 310 ft. long x 60 ft. wide. It is used only for storing cars, and contains three tracks, with a capacity of twenty-five cars.

Every night each car is overhauled, the gears and trolley wheels are greased, the commutators are examined, the controllers are thoroughly cleaned, the tips are sandpapered and oiled, the brake shoes and nuts are examined, and the car is washed. Trifling repairs are done on the spot by the inspectors. It requires but three or four men to overhaul all the cars necessary for operation, and the perfect condition of the equipment more than repays the company for the expense incurred. Should a car wheel be worn flat, due to skidding, it is at once removed and replaced.

The repair staff consists of: Day staff—One foreman, two mechanics, one electrical mechanic, one blacksmith, one carpenter, one painter, one laborer. Night staff—One foreman, three greasers and repair men and two cleaners.

SNOW SCENE

Some of the results noted by this system might almost be known as "records," for during the two years' operation only one armature has been burnt out, and only two armatures have been destroyed by worn bearings; no controller has yet been destroyed, and the covers are as good as new; no gear or pinion has yet been destroyed or replaced, and the braking is perfect, one special feature being the noticeable ease with which the motormen stop a car on a grade.

The patrol wagon makes a complete circuit of the whole line once a week, attending to any repairs necessary and testing the span wires for insulation. As a result there has as yet been only one break in the trolley line.

MONTMORENCY FALLS, SHOWING DAM

Taking the eleven months of the last year's operation, the last month's accounts being not yet completed, for the year ending June 30, 1899, the total number of car miles was 914,926, and cost of maintenance $87, 008, or .095 per car mile. Of this amount .016 per car mile was chargeable to snow removal. This amount may be better appreciated when one understands that this sum means that every car must earn $1.70 a day to pay the expenses of the snow removal alone. Payment of all unsalaried employees amounted to .064 per car mile, and was by far the greatest item. The cost of maintenance of electrical equipment was .0019 per car mile; that of car bodies and trucks, .0050 per car mile, and that of ways and buildings, .0081 per car mile.

POWER DEVELOPMENT, POWER HOUSE AND SUBSTATION

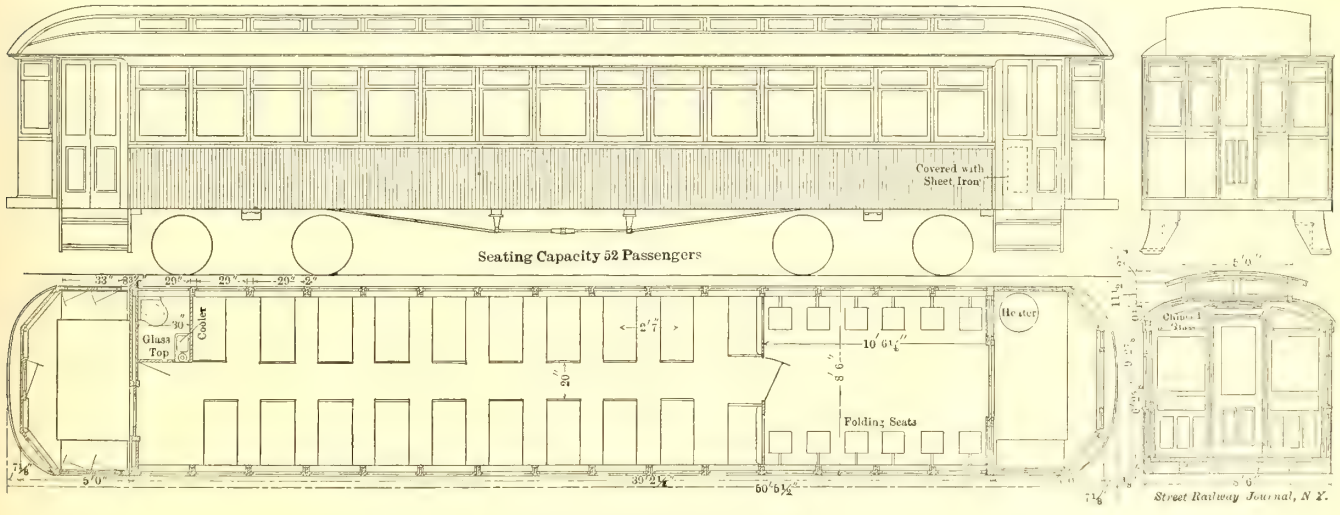
This electric railway, together with all electric lights and motors used in Quebec, is operated from water power developed at the celebrated Montmorency Falls, 7 miles distant from the city.

The total height of the fall is 267 ft., down which the water falls perpendicularly in a beautiful white, foaming turmoil of water to the rocky chasm beneath. An im-

mense concrete dam, 250 ft. wide, has been constructed across the river, 100 ft from the brink of the falls, which, though in no manner despoiled of their beauty, are yet turned to some industrial account. A cribwork wing dam has also been erected, containing several large openings in the bottom acting as water passages, permitting the water to enter the forebay free of all rubbish, which is left floating on the surface, and also free of frazil ice, that bugbear to Canadian water power development, this being completely swept away and over the falls by the swift current outside the forebay. The entrance to the penstock is in the gate house, situated at one end of the dam, whence the water flows in the huge enclosed steel pipe, 8 ft. in diameter, to the power house, 2560 ft. distant, following a sinuous path under the very brow of the hill.

The power house, a one-story limestone structure, 150 ft. long x 50 ft. wide, is located on the side of the hill, 208 ft. below the brink of the falls; the actual working head, however, is only 195 ft., the remainder being destroyed by frictional loss. The equipment consists of four 52-in. water wheels, each delivering 1000 h.p. at 286 r.p.m., built by the Stilwell-Bierce & Smith-Vaile Company, of Dayton, Ohio, the speed being regulated by four Geisler electro-mechanical governors, which raise or lower the cylindrical wheel gate, controlling the admission of water to each wheel. Each wheel is direct-connected to a 600-kw. two-phase S. K. C. alternator, generating current at a frequency of 66 cycles per second, and at a pressure of 5500 volts, at which it is transmitted direct, but is reduced by line drop to 5000 volts at the substation. Two 30-kw. bi-polar exciters, direct-connected each to a 11-in. wheel, rated at 50 h.p. at 1200 r.p.m., furnish current for the generator fields.

From the wheels the water passes into a discharge tank, whence a certain quantity is delivered to a cotton mill situated some distance below, the head being sufficient to operate 1000 h.p., the amount contracted for.



From the power house the current is transmitted to the substation by means of two separate pole lines, each carrying eight wires—four from each machine. The generators are not coupled in parallel at the power house, but are run separately, this being found necessary on account of the violent fluctuations of the street railway load affecting the city lights when all were operated in parallel. The machines, however, not running the railway load are coupled in parallel at the substation for the incandescent lighting and power service.

The substation, situated in Quebec near the St. Charles River, is a two-story limestone structure, containing the office of the lighting and power department, besides the electrical installation, testing and storerooms. For lighting and power purposes in the city the pressure is reduced to 2000 volts by step-down transformers of the Stanley make. For arc lighting two 200-kw. two-phase S. K. C. synchronous motors are each coupled direct to two 125-light Brush arc machines.

INTERIOR OF CHURCH OF ST. ANNE DE BEAUPRÉ

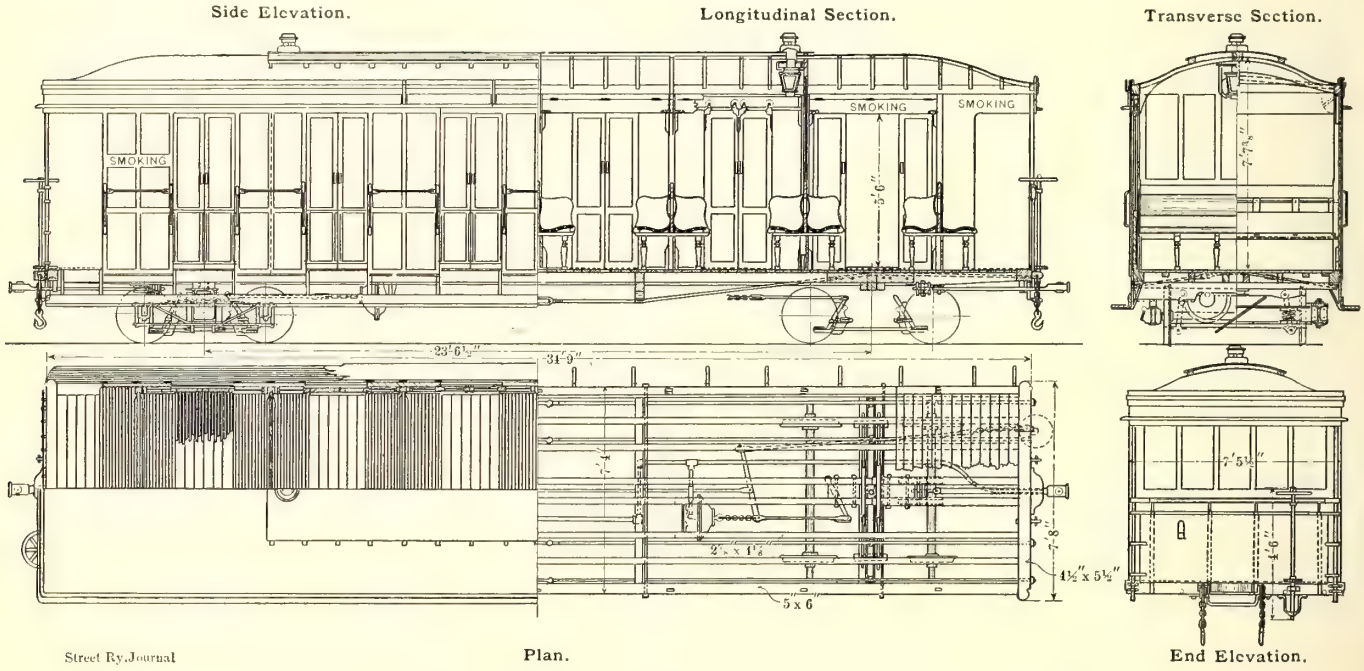
For the street railway load there are two motor-generators, each consisting of two separate machines direct-connected by an insulating leather coupling. The alternating current side is a 600-kw. two-phase S. K. C. synchronous motor running at 286 r.p.m., and operating under a pressure of 5000 volts direct from the line; the direct current side is a six-pole 450-kw. Canadian General Electric generator, delivering current to the street railway at 550 volts. Each motor-generator is started and brought up

CAR FOR HIGH SPEED RAILWAY

to the speed of synchronism by a 30-h.p. two-phase S. K. C. induction motor, after which the synchronous motor takes the load. Two 30-kw. Bullock exciters direct-connected to two S. K. C. induction motors are used for exciting the fields.

The switchboard is of the standard General Electric railway type, consisting of five white marble panels. A Thomson integrating wattmeter is placed on this board, and the amount of power consumed by the street railway may thus be accurately determined. Formerly the street railway was a distinct and separate company and purchased power from this station at a certain contracted price per kw. hour, this leading to the introduction of the wattmeter.

SUBURBAN EXTENSIONS



The Q., M. & C. Railway Company, besides running the Quebec city system and supplying the street and residential lighting and power, operates a steam railroad 21 miles long, from Quebec to St. Anne de Beaupré, a celebrated Roman Catholic shrine, this, in fact, being its original business. This latter road will shortly be converted to electricity, the main line being extended 9 miles, making a 30-mile run, and a branch line of 6 miles to be constructed. The total length when completed will be 36 miles, all of single track.

The same roadbed will be used, the 56-lb. rails being bonded with two No. 00 copper bonds. The overhead construction will be standard, wooden poles, of course, being used. There will be two trolleys side by side, in multiple, each with a No. 0000 copper wire. No feeders are required, as the size of the trolley wire will keep the drop within bounds.

The road will be equipped with 50-ft. cars, double trucked, of a type similar to that used on the Detroit-Ypsilanti road, and are illustrated herewith. Each will provide seating capacity for fifty-two passengers, and will be operated by four 50-h.p. Westinghouse motors, capable of attaining a speed of 50 miles an hour. Two trolley poles, arranged tandem on top of the car, will supply all the power required for starting or running up a heavy grade, without sparking in the least. Each car will be provided with Westinghouse standard air brakes, and will weigh 4 tons, made up as follows: Car bodies, 25,000 lbs.; truck, 12,000; motor and equipment, 10,800.

The ordinary service will be hourly, but during the summer months it is thought that it will be necessary to reduce it to half-hourly on account of the rush of pilgrims to the shrine at St. Anne de Beaupré.

For supplying power to this road one 600-kw. Westinghouse double generator is to be installed at the Montmorency Falls power house. The direct current side of this will deliver current at 550 volts, feeding directly into the two trolley lines at the power house, and taking care of the first 10 or 12 miles; the alternating current side will generate a two-phase current at a nominal pressure of 400 volts, which, by means of two 125-kw. single-phase transformers using the "Scott connection," will transform to a three-phase at a pressure of 1000 volts, at which it will be transmitted to a substation located 10 miles from the eastern end of the line. Here it will be reduced to a two-phase again, and operate a 200-kw. Westinghouse rotary converter, thus obtaining current at 550 volts to feed that end of the line.

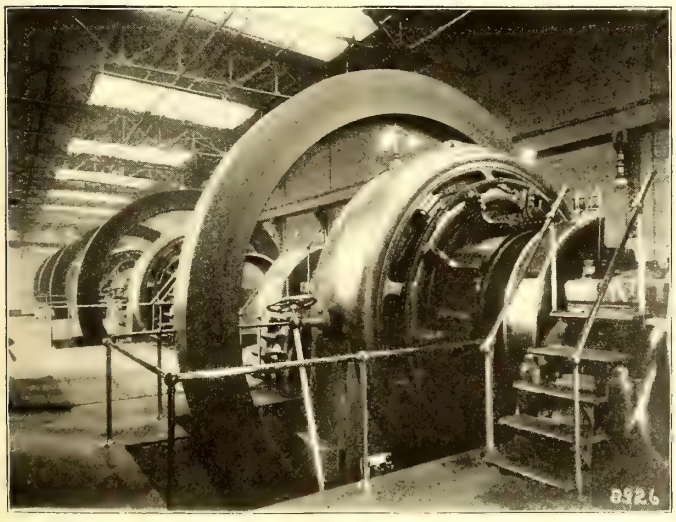
LIGHT RAILWAY CAR USED BY THE SOUTH WALES GOVERNMENT RAILWAYS

The officers of the Q., M & C. Railway Company are: H. J. Beemer, president; E. A. Evans, general manager; W. R. Russell, general superintendent; William Langford, hydraulic engineer; D. E. Blair and Lewis Burran, electrical engineers, in charge of the street railway and the lighting and power departments respectively.

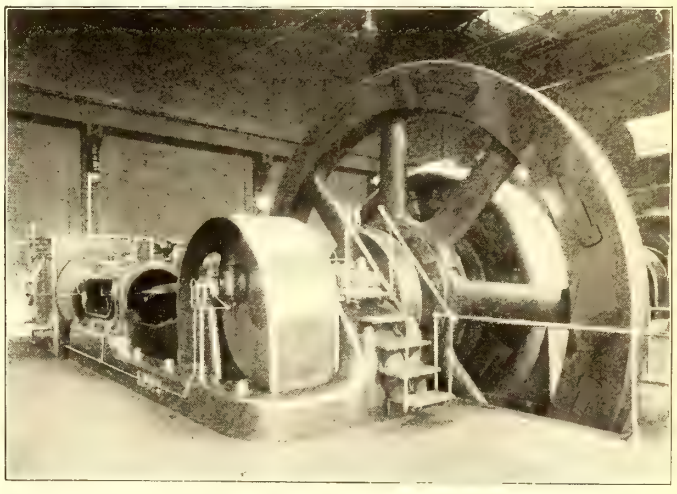
Light Railway Car

The accompanying diagram shows plan, side elevation and section of the standard car for steam tram or light railway service used by the New South Wales Government upon the steam tramways owned by it. These cars have been in service for from fifteen to eighteen years and seem admirably suited for the work they have to perform. Their seating capacity is seventy passengers, but when heavily loaded and the standing room is occupied they frequently carry 130 to 140 people. The weight empty is 11,200 lbs., including trucks. The latter are, of course, very light and are equipped with cast steel wheels. The drawing is reproduced through the courtesy of W. Thow, chief mechanical engineer of the New South Wales Government.

Some Electrical Features of the Power Station of the Consolidated Traction Company of Pittsburgh

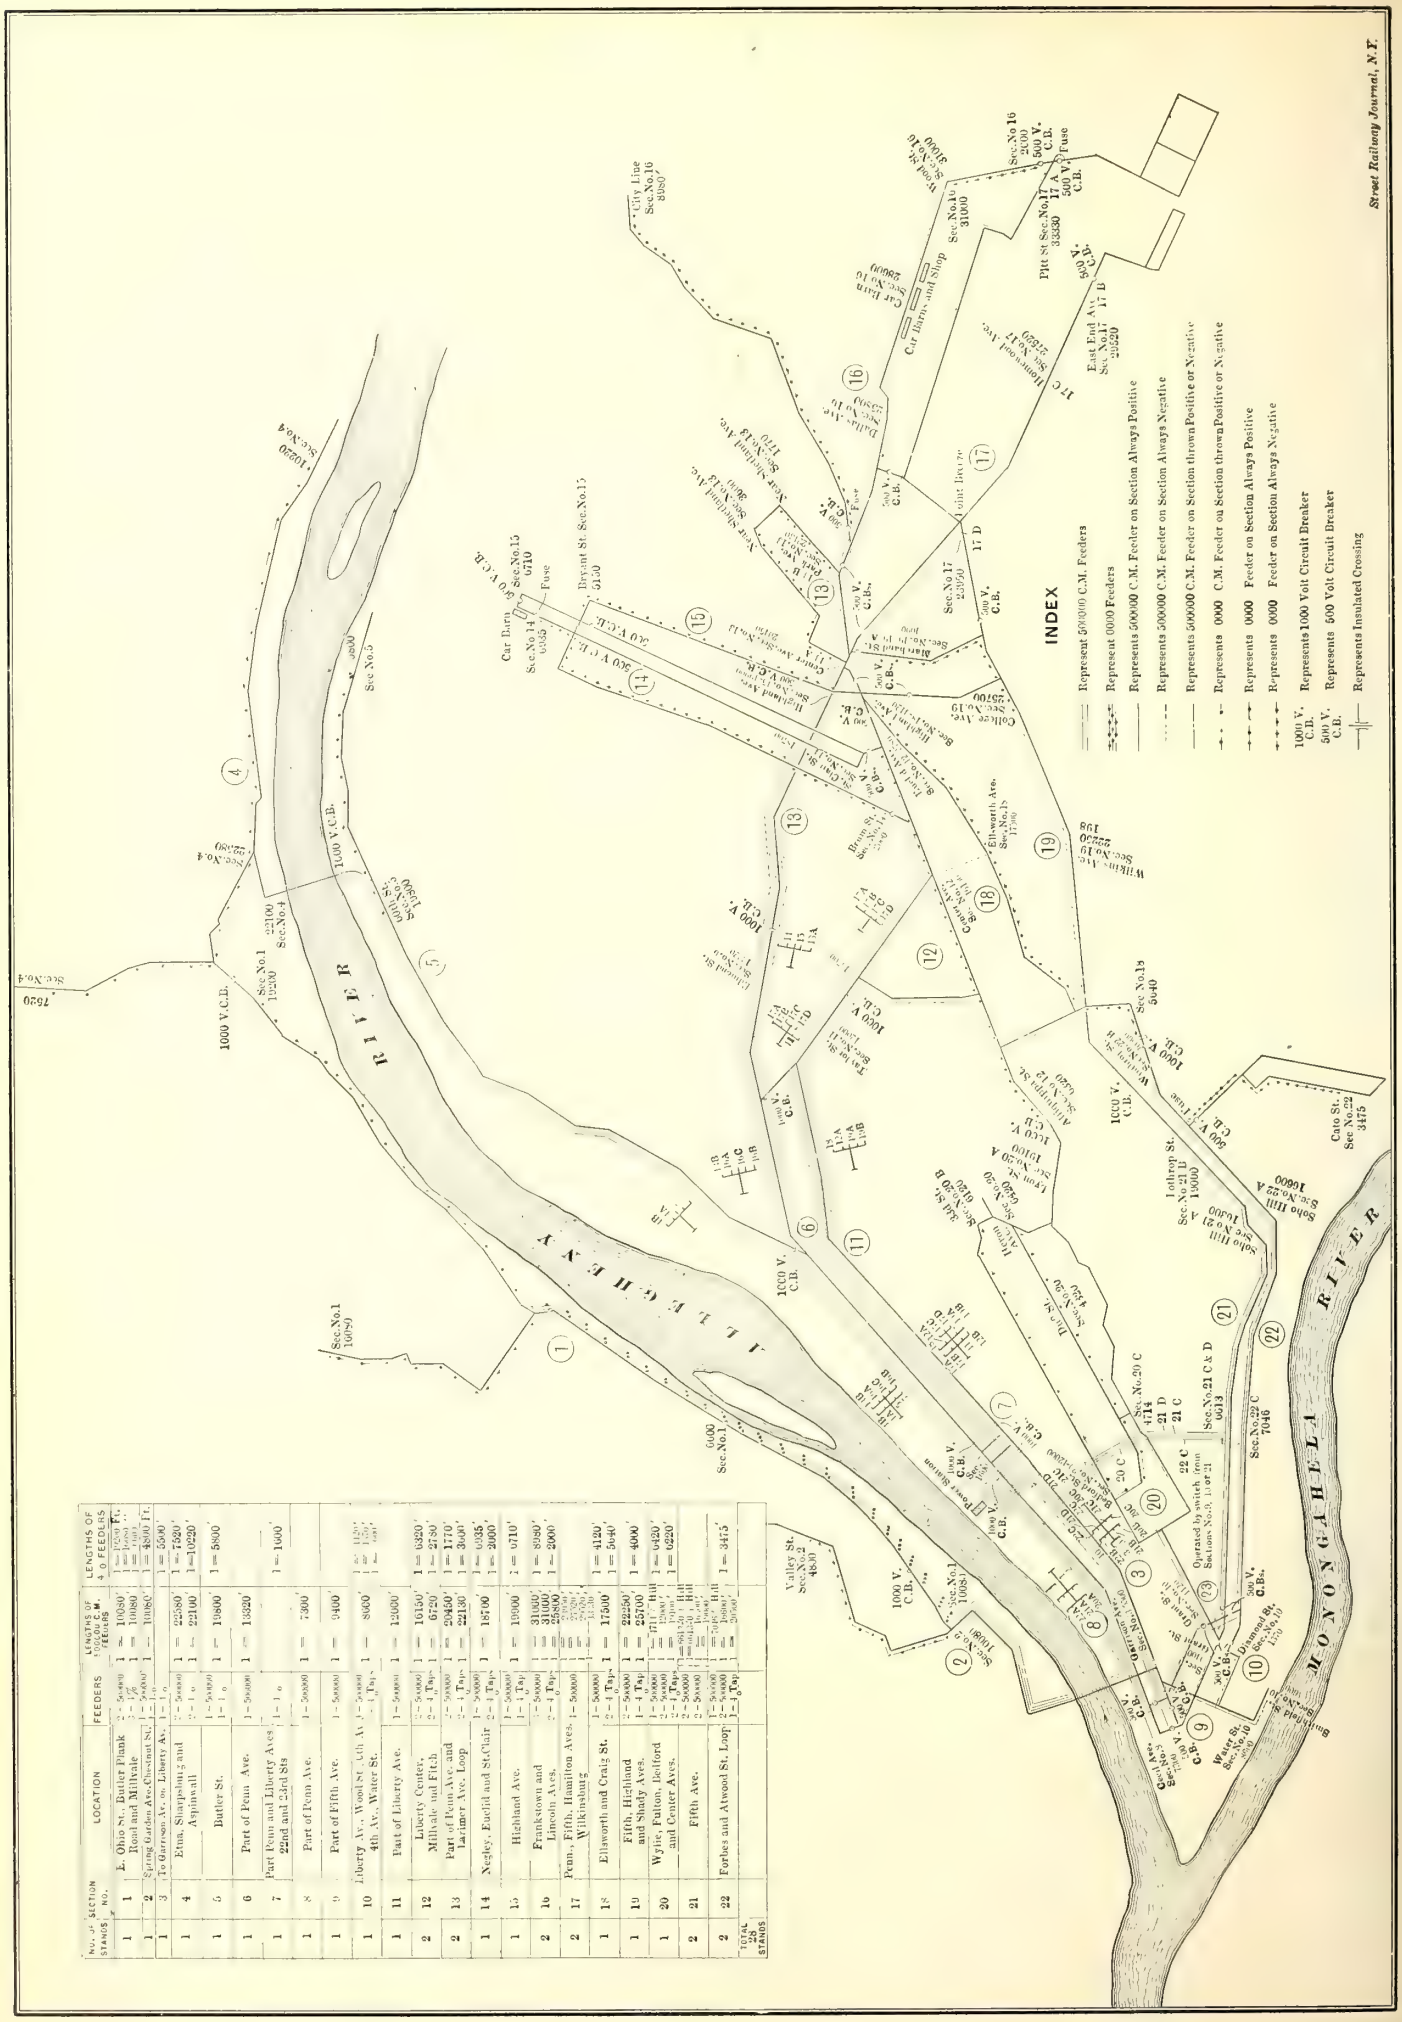


An extended description of the electric railway system of the Consolidated Traction Company of Pittsburgh was published in the STREET RAILWAY JOURNAL for March. This system, as will be remembered, is a most extensive one, and the power station which has recently been completed, includes a number of radical innovations from standard practice. The extent of the subject, and the fact that the station at the time of going to press was not entirely completed, precluded the description of a number of details of interest in regard to the station equipment, and these will be briefly mentioned herewith.



COAL CONVEYOR

INTERIOR OF BOILER ROOM



GENERATOR SIDE OF UNIT

LOW PRESSURE SIDE OF UNIT

The power station is located at Twentieth Street, on the Allegheny River, from which water is obtained for condensing purposes. The tracks of the Baltimore & Ohio Railroad and the Pennsylvania Railroad are close to the station. Coal can be secured from either, or from barges on the river. The station itself is built of Pompeian brick, with Cleveland sandstone trimmings, and measures 275 ft. x 115 ft. The coal is received at the river end of the station. The cars run over a receiving hopper, into which they discharge their load. The coal is being carried by a Meade coal conveyor, with automatic weighing bucket, to a second hopper, or coal storage bin, located over the boilers. The conveyor is driven by a 16-h.p. electric motor, and has a capacity for handling 40 tons per hour. A view of the receiving end of the conveyor is shown in one of the accompanying engravings.

The boiler room contains six batteries of sectional water tube boilers of a special design, made by the Babcock & Wilcox Company, and each battery is provided with a separate unlined iron smokestack. Each stack is 66 ins. in diameter, and rises 147 ft. above the grate bars. The furnace is of the Hawley down-draft type. In order to economize floor space the boilers are made shorter and higher than usual. Each boiler contains about 4000 sq. ft. of heating surface and is made up of eighteen sections of

DIAGRAM OF FEEDERS FOR OPERATING ON THE THREE-WIRE SYSTEM, CONSOLIDATED TRACTION COMPANY—PITTSBURGH

tubes, each 15 ft. long with three 36-in. drums, 20 ft. long. The boilers are designed to carry a pressure of 200 lbs. to the square inch and were tested under hydraulic pressure to 300 lbs.

The interior of the engine room is of Pompeian brick, and is finished with enameled brick wainscoting with slate cap. It measures 270 ft. x 55 ft.; and is designed to contain eight units, of which six are at present installed. Each unit consists of a 1560-h.p. cross-compound condensing Corliss engine, built by the Pennsylvania Iron Works Company, and connected to an 800-kw. generator. The engines run at 80 r.p.m., and their cylinders measure 30 ins. and 54 ins. x 48 ins. stroke. An automatic oiling system is used for all the bearings. The main supply of oil is kept in a reservoir placed near the roof of the building, and from

VERTICAL ADJUSTING DEVICE FOR GENERATOR

DATA CURVES OF GENERATOR

that point is piped to the different bearings. After passing through the bearings it descends to the basement, from which point it is filtered, and is then pumped back to the tank. An automatic arrangement is provided by which if there is any lack of oil supply in the tank a whistle is blown in the engine room.

The generators are of the standard Westinghouse rail-

VIEW OF POWER STATION

way type, with a nominal capacity of 1460 amps., and actual capacity of considerably more under different conditions, as mentioned later. The generators run at 82 r.p.m. at no load, and give then 500 volts. At nominal load, which is 1460 amps., they are designed to run at 80 r.p.m., and give 550 volts; and at 75 per cent overload they run at 77 r.p.m. The generators are guaranteed to carry 1820 amps. continuously, with a rise of not more than 40 degs. Cent. in any part of the machine; and also to carry 2560 amps., which is 75 per cent overload, with not less than 550 volts for a short period. The commercial efficiency of the machine at one-fourth load is 90 per cent; one-half load, 92 per cent; three-fourths load, 93 per cent, and full load, 94 per cent. The output of the machine at different rates of loading is shown diagramatically in the accompanying data curves. The machine is also guaranteed to produce no sparking within the limits of no load and 50 per cent overload, or to require any shifting of brushes between these limits. It is also guaranteed not to buck at the opening of the circuit breaker at 2500 amps. The machine is tested before leaving the works to stand an alternating e.m.f. of 3500 volts. The frame is mounted on an adjustable bed plate, which provides for both a lateral and vertical movement. The former is cared for by regular guide rails; the latter is intended to provide for the wear in the bearings, and is accomplished by means of a large wedge-shaped casting which supports the generator and can be moved in either direction by means of a screw adjustment. This device is illustrated in one of the accompanying engravings.

The generators are over compounded, so that the potential at the terminals increases about 10 per cent from no load to full load. The shunt and series coils are separately wound, and are removable at will. The armature spider is pressed and keyed upon the engine shaft, and may be drawn off when desired, should that ever be necessary.

without interfering with the permanent arrangement of the commutator and windings. The armature windings are made from bars of copper forged into proper shape, on cast iron formers and are insulated with mica and prepared filler board. They are held in the slot by retaining wedges of hard fibre, avoiding the use of bands.

INTERIOR OF ENGINE ROOM—PITTSBURGH

The switchboard, as described in the March issue, is built for the three-wire system, and is of an extremely novel pattern. Although the road is still operated on the two-wire system, the arrangement of the feeders for the three-wire system has been decided upon, and the overhead system is so arranged that a change to the three-wire can be effected without any alteration of the feeders or overhead structure. The method to be employed is, briefly, to operate the down-town sections positive and the suburban sections negative, and provide certain alternate outlaying feeders adjoining each district for transposition from one side to the other. A change, however, to the three-wire system is considered impossible until all the substations now in operation are shut down, and this will prevent a change for some time.

A diagram of the arrangement of feeders for three-wire distribution is shown on page 504. As will be seen, part of the feeders are arranged to be operated positive, part negative and part to connect to either side to balance the system.

The main object in the painting of cars should be to secure a hard, smooth surface which will hold the varnish with the very smallest amount of material; the thinner this surface is the better. From paper at the Boston Convention, 1898.

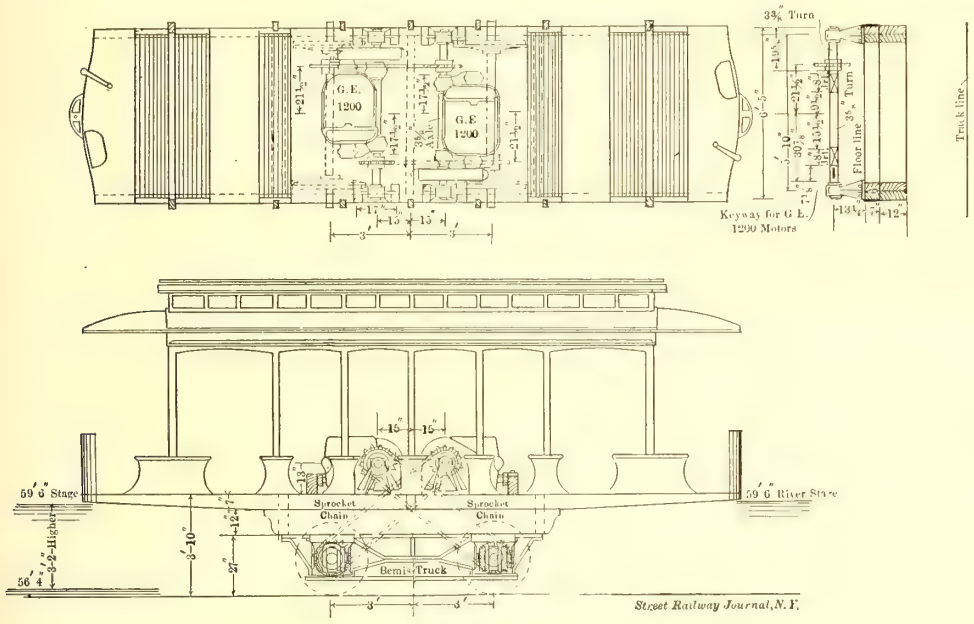
A Novelty in Car Construction

The accompanying engraving shows a somewhat novel type of open car recently put in service on the lines of the Montreal Street Railway Company. The cars are run on a loop, and the inside of the car is partly closed, the idea being to do away with the wire screens hitherto used, and also to prevent wet seat ends. The cars are fitted with pantasote curtains, which are found very effective in wet weather and on cold days.

The right side of the car, the one not shown in the engraving, is finished similar to an ordinary open car. The photograph is reproduced through the kindness of F. L. Wanklyn, manager and chief engineer of the Montreal Street Railway Company.

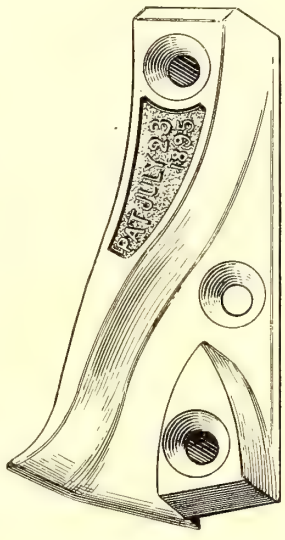
NOVEL OPEN CAR—MONTREAL

Life consists of motion, and the more we increase the facilities on the part of mankind to move its individual units from one point of the earth's surface to another point, the more we extend civilization in the higher sense of the term. From address at the Boston Convention, 1898.



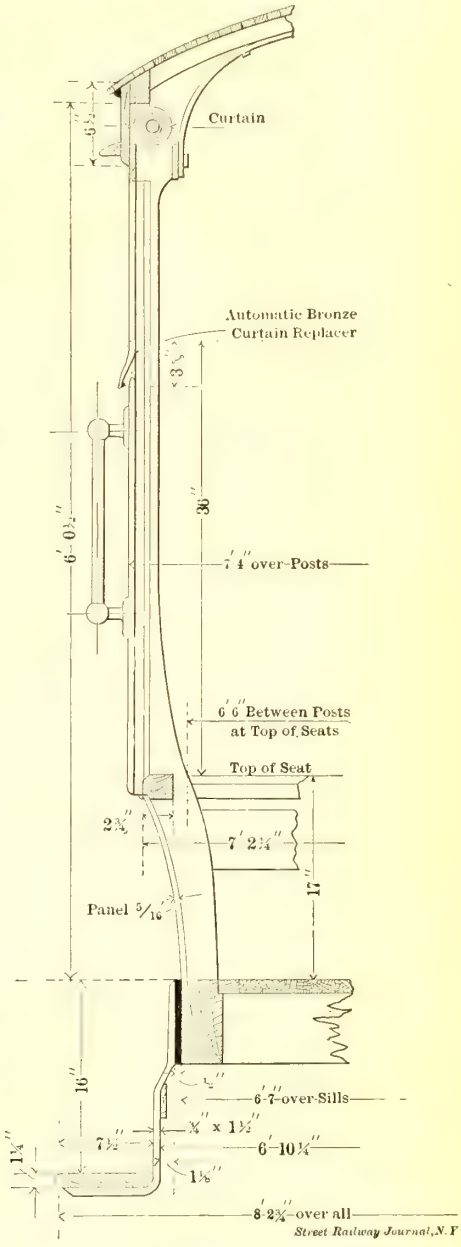
Notes From Cincinnati

The Cincinnati Street Railway Company now controls all the street railway lines operating in the city proper, but permits some of the cars of a suburban line to pass over its tracks to the business center of the city. The system also connects with and receives the passengers at College Hill with the high-speed line that runs between Cincinnati and Hamilton. The double trolley still holds its own, and the grooved type of rail is the standard.



Since the last description in the STREET RAILWAY JOURNAL of the street railway systems of this city the Cincinnati Street Railway Company has bought that portion of the line located between the Zoological Gardens and Fountain Square that was formerly controlled by the Cincinnati Inclined Plane Street Railway Company. Since this purchase the company has abandoned the operation of the inclined plane on which the cars were formerly lifted to the heights, and the cars now reach the top of the bluff by making a detour around it. The company has also absorbed the Mt. Auburn Cable Railway, now known as the Sycamore Street line and which is still operated by cable, being the only remaining cable line in the city. Some recent additions have been made to the power plants, of which there are six still in operation—five electric and one cable—the grades and other conditions being such that a central station is not thought to be practical. Direct coupled units have become the standard for new construction, and the later installations are of this type. In this connection it is interesting to note that this company was among the first to install a direct coupled unit. Its original unit consisted of a Buckeye engine and a Siemens & Halske generator, which are still in operation and giving reasonable satisfaction. During the first year of the service of this unit a great deal was said about the impracticability of direct connection, but the wisdom of the company in its first choice has been fully demonstrated by the results.

Considerable pressure is being brought by the city authorities at Cincinnati against the street railway company to require it to adopt the underground or conduit electric system. To this the company objects for various reasons, chiefly because a good many sections of its trackage are under water during the periods of high water in the Ohio River. The company has recently, at its own expense, made a careful survey of its line and noted the limits of the water level at both the high and low stages, and which are printed in this connection, and which show the depth to which the rails are submerged and also the extreme rise and fall of the water. From this it was found that about 34 miles of the streeet on which the tracks are laid were subject to overflow, and this circumstance, it is claimed, would prevent the operation of the underground trolley.



In order to provide for operating the lines over the submerged section of the streets the company has recently designed a train, consisting of a motor and trail car, which will be operated in the stages of high water. The motor car for this purpose is illustrated in the accompanying diagram from which it will be seen that an ordinary open car is employed, but it is raised above the truck by means of beams. The motors are supported on the floor of the car and transmit their power to the axles by means of sprocket chains and gear. It is the intention of the management to increase the weight of the motor car by having a number of discarded motor gears pressed on to the axles. The trail car consists of a nine-seat open car of the same design as the motor car, but without motor. It will be

CAR FOR FLOODED TRACKS

CURTAIN REPLACER

SECTION OF SIDE OF CAR SHOWING CURTAIN REPLACER

raised about 12 ins. above the truck in the same manner, so that it will readily couple to the motor. In connection with this train platforms will be provided on the side of the street at certain locations so that people who are required to patronize the train will have ready access to the cars.

The table showing the portions of the track liable to flood is given below.

Route	Total Length in Feet of Route Under Water When Stage of River is 71'—0½"	Stage of River Necessary to Reach Track at the Lowest Street Level	Stage of River Necessary to Flood Conduit at the Lowest Street Level
East End	25,550	55.92	53.92
Delta avenue	26,200	55.92	53.92

Sixth street	9,000	64.85	62.85
Total	193,700	....	....

A CURTAIN REPLACING DEVICE

All the open cars of the Cincinnati Street Railway system are equipped with a curtain replacing device which was invented by the president of the company. This consists of a brass lug about 4 ins. long, having a curved channel of the same width as the curtain channel in the posts, and is set into the posts on the inner faces about 2 ft. below the top of the post. If for any cause when a curtain is pulled down it leaves the guides, it can be immediately returned to its place by letting it run up outside the posts, when the replacer will turn it back into a proper position, and it can then be drawn down in the ordinary manner. The replacer is held in position by two screws, and is not of sufficient depth to weaken the post. The device is cast in the company's foundry, and finished up in the machine shop, and is a very inexpensive appliance as compared with its advantages.

ILLUMINATED SIGNS

All the cars of the Cincinnati Street Railway Company are equipped with an illuminated sign which can be read in daylight or night time. For their use two stationary plain glass panes are placed in the deck on each side at the middle of the car, and also in the deck lights above the hoods. These are fitted on the outside with grooves or guides, into which the sign proper is slid. The sign consists of a sheet of glass of the same size as the stationary panes, but with the groundwork painted black, leaving the letters outlined; these letters are about 4 ins. in height, and there is a narrow white border around each letter. This makes a sign that is readily read in daylight, and at night it is illuminated by the lamps in the car. These signs can be read for a considerable distance as the car approaches, and are much more satisfactory both to the patrons and operating company than any signs heretofore used.

MOTORS, TROLLEY WHEELS AND BEARINGS

Four types of motors are employed on the cars of this system, the type being adapted to the character of the grades and of the cars. These consist of the General Electric 800 type, the General Electric 1000, the General Electric 1200 and General Electric No. 58. Power for operating the different departments of the repair shop is derived from motors which are made over from the old D 62 type of generators formerly employed. Quite a number of these are in use, and have proved very satisfactory. There are besides twenty small power motors employed about the shops and the different car houses of the system.

The company manufactures its own trolley wheels, the blanks being cast in its brass foundry. These blanks are turned up with automatic tools of special design on a lathe which is operated by an unskilled workman. This man receives only $1 a day, and is able to turn up and finish 125 wheels in that length of time. The wheels are cast from a mixture consisting of eight parts of copper to one of tin.

The company employs bronze bearings for armature journals in preference to babbitt, as it was found that the babbitt would frequently squeeze out from the shell and allow the armature to come down in contact with the fields, and in case of excessive heat would melt.

At one time after the consolidation of the various roads there were fifty-four different types of car axles in use, to suit the various types of motors and trucks. To reduce this number the company selected two types of trucks—the Peckham and the McGuire—and these have consequently been adopted as standard.

REPAIR SHOPS

The new repair shops, which are located at Chester Park (7 miles from the center of the city), and which were illustrated and described in these columns in the issue of February, 1898, are still of ample capacity for all repairs, and are also turning out considerable new work. Thirty new cars have recently been built here, and they are very creditable in design and finish. Some special features in mechanical appliances and methods employed in these shops were published in the June issue.

The different departments of the repair shop are heated by means of the American Blower Company's system, which consists of enclosed fans 140 ins. in diameter and driven by a steam engine. These take the cold air in through a nest of steam pipes, and deliver it through large galvanized pipes to the different parts of the building. Two of these fans are provided for heating the paint shop proper, which is 200 ft. x 300 ft. and 20 ft. high, and during the past winter, with the outside temperature 14 degs. below zero, a temperature of 70 degs. F. was easily maintained in the shops.

In the construction of the repair shop the roof trusses were constructed of wooden beams in preference to metal for the reason, it is claimed, that in case of fire among the cars or in the building the timbers would char and hold up longer under the heat than would a steel structure, which is liable to buckle and give way under excessive heat.

For shifting coal and freight cars about the premises, and for handling the street cars in the yard, an old motor car, with rather a short body, is employed. This car has sufficient power for handling three or four loaded freight cars on a level and around curves, and has proved to be a very convenient and cheap mode of shifting cars.

All transfer tables in the shops and car houses are operated by motors, which take their current from conductors placed below the floor level in slots.

One of the most interesting features of the repair shop is the brass foundry, in which is cast all the brass work required in the operation of the system, including car trimmings, trolley wheels, commutator bars and bearing shells. It is generally supposed that pure copper cannot be cast into commutator bars without there being defects in the

way of blow holes, etc., but in the experience of this company no difficulty is found in making perfect castings, using copper wire scrap. The various parts are cast in groups in a single flask, are afterward separated and trimmed on a band saw, and then smoothed upon an emery wheel.

The twelve forges in the blacksmith department are all constructed on what is known as the down draft system, so that there is no smokestack or flue above the forges. The hood for the down draft is at one side of the forge, and the air is exhausted by a fan located in one end of the shop. This fan is so designed that part of the gases from the furnace are directed into the blast tube and returned to the forge for blowing the fire. By this arrangement the combustion is so perfect that no smoke is ever seen to emerge from the main stack into which the fan discharges its current.

The blacksmith department is provided with a 1500-lb steam hammer, manufactured by the Morgan Engineering Company, of Alliance, Ohio, and the bending tools, shears and punching machines are driven by a motor made over from a D 62 generator, as before described. In this department by the means of the steam hammer the company makes its own dash rods, etc.

Labor Saving Tools and Methods in the Repair Shops of the West Chicago Street Railway Company

The repair shops of this company, which are located at Madison and Fortieth Streets, and which were built in October, 1890, are still among the largest, if not the largest, of any street railway repair shops of the country. The floor space of all the buildings, including that of the wood department, iron department, erecting shop, paint shop, car storage department, and the various offices and auxiliary buildings, aggregates 1,586,552 sq. ft. Here all the repairs of both the cable and electric lines of the system are made. The tool equipment is very complete, and has recently been increased by the addition of new lathes and planers, and by a rail sawing machine, which is illustrated in Fig. 1.

Electric motors have recently been installed for driving the shafting in the different departments, the current being obtained from the trolley line, and the engine and boiler equipments have been abandoned. The rail saw referred to above was recently purchased from the Q. & C. Company, of Chicago, and is utilized not only for sawing rails, but for trimming grip dies and for cutting angle iron or bars of any shape. The bars from which grip shoes are made are first cut up to standard lengths on this saw, several bars being clamped together and cut at the same time. These are then trimmed on the saw by being clamped in groups of six or seven, as shown in the illustration. Formerly this work was performed in a blacksmith's shop, where it was necessary to heat the bars before trimming. Now the work goes on by means of the saw at a greatly reduced cost. In this connection it is interesting to note that the company now manufactures all its own special work, provision being made for erecting under a temporary shed located in the back yard of the machine shop proper. In the construction of crossings a change has been made in the method of abutting the ends of the short rails against the sides of the through rails. Formerly it was the custom to cut off the base of the rail and part of the web, so that the web of the short rail would rest on the base of the main rail. As this gave only a narrow support to the end of the rail, and because it was found to cut into the base, the practice has been adopted of preserving the base of the short rail and causing it to rest upon the base of the main rail. To accomplish this a wedge-shaped piece is cut out of the web next the base, of sufficient depth and length that when the base is bent up after heating, it just fits on the base of the main rail and brings the top of the rail to line, but furnishes a solid support for the end of the short rail.

A double furnace has been installed in the blacksmiths' shop, having doors which are lifted by balance levers, as shown in the engraving Fig. 2. The special feature of this furnace, and one worthy of note, is the location of a 4-in. pipe across the front, just beneath the doors. This pipe is slotted on its upper surface, and conveys a blast of air, which, issuing under pressure through the slot, creates a strong up draft when the doors are opened, and so dissipates the heat that the attendant can stand very near the furnace when the door is open without inconvenience, and with his tongs place new blanks in the furnace or remove those when sufficiently heated.

A brass foundry has also been recently installed, and occupies a portion of what was formerly the iron storeroom. The foundry is 34 ft. x 32 ft., and is provided with four furnaces, as shown in the illustration, Fig. 3. The molding troughs are located on two sides of the room, and the flasks, when the charge is ready for pouring, are arranged as shown in the illustration. A core oven is provided, which stands near the furnace, as shown in the illustration.

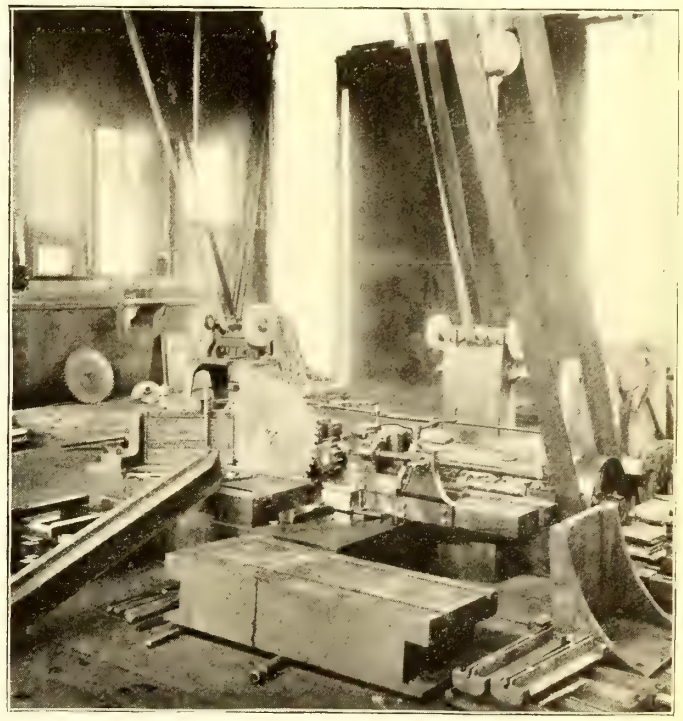

FIG. 1.—METAL SAW

Since the installation of the brass foundry the company manufactures its own brass and copper work of every description, including trolley wheels, trolley harps, overhead switches and car trimmings, as it is now the policy of the company to manufacture all its own supplies, and not to go outside for anything that it is possible to produce in its own shops.

In connection with the machine shop proper a tool room has been partitioned off at one end, in which all the small tools are systematically arranged. This shop is in charge of an attendant who deals out the tools to the workmen on their personal checks, so that a careful record is kept of all tools. In the tool room is located a multiple drill, or rather, a drill with revolving head, which carries tools of

different descriptions to the number of six. This drill is operated by the tool-room keeper, who drills and finishes many of the brass pieces. Here, also, the principal repairs on the registers are made.

Owing to a recent ordinance, requiring that all of the cars of the city be equipped with fenders, the West Chicago Street Railway Company has equipped its cable and electric cars with fenders of its own design and manufacture.

In the matter of motor repairs it is the practice in the motor repair department to renew the motor bearings every sixty days, without waiting for them to be worn down, and at the various depots where light repairs are made in the armature brushes of the General Electric motors they are changed every day and are put to soak in vaseline. By changing brushes a gloss is formed on commutators, and wear is prevented. On one of the electric lines of the West Chicago, quite a number of the Candler self-oiling trolley harps are employed. By the use of these the life of the trolley wheel is greatly lengthened, and they now last on the average of thirty days.

In the motor repair department only four men are employed for making all the armature and field repairs on 400 motor equipments employed on the lines of the West Chicago system proper, and they also take care of the repairs on motors of three or four of the leased lines. Some of the commutators that have been in service for four years have never been turned down. Others have required turning several times. In the opinion of the foreman of the armature department, the damage to the commutator is not from actual wear, but from sparking, due often to the variation in the neutral point of the brushes, but more often to the improper handling of the car. The amount of resistance in the shunt coil, he also claims, has much to do with the flat spots on the commutator. Where two motors are mounted on the same truck with unequal resistance in the shunt coils, it is found that the one with the least resistance receives more current and, consequently, tends to run faster and do more work, hence danger to the commutator and winding is incurred. A remedy is found in mating motors properly.

In repairing armatures of the Westinghouse No. 12 motors, it is customary to wind the armature complete with triple insulated wire. Better success is had than with made up coils. This method gives an opportunity to place additional insulating material in the slots, while the ends are reinforced with a bit of mica, and this method avoids the danger of employing an imperfect coil or injuring the insulation of the coil in putting it in place. The cost of the winding complete (including labor and materials) is found to be only a trifle more than made up coils alone, while the life is materially prolonged.

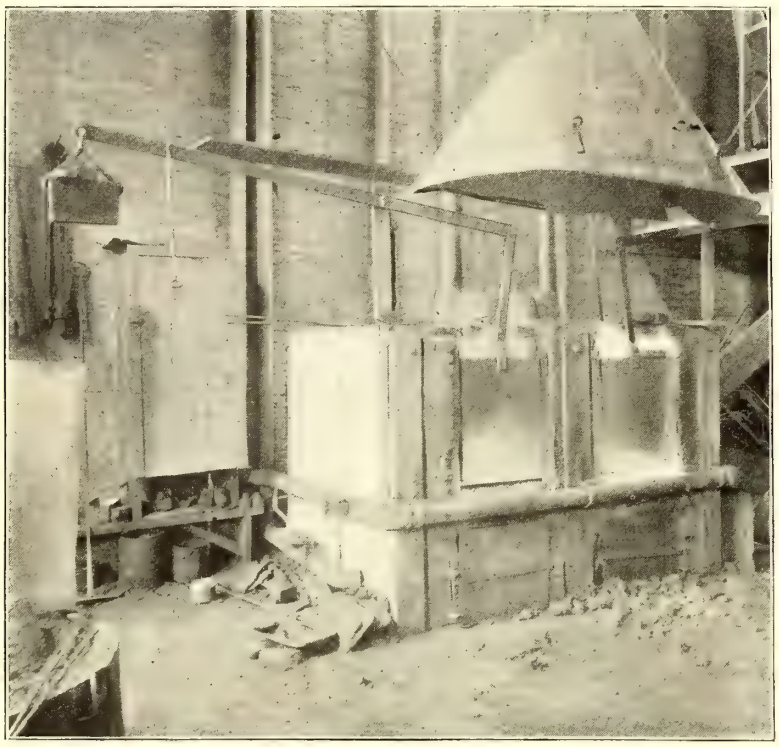

FIG. 2.—REHEATING FURNACE WITH PERFORATED BLAST PIPE FOR COOLING

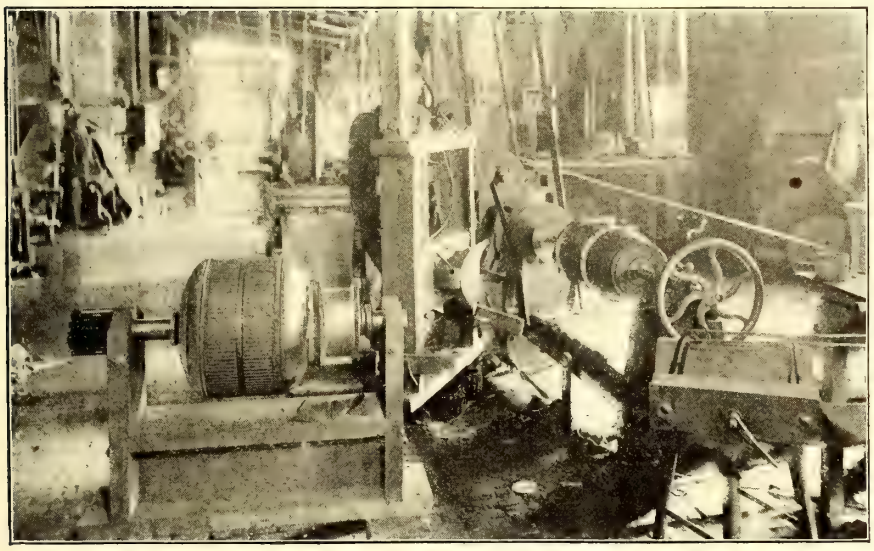
FIG. 3.—NEW BRASS FOUNDRY

Kinks From Indianapolis

In repairing the armatures of the Westinghouse No. 3 motor the chief electrician of the Indianapolis Street Railway Company has adopted the plan of placing a threaded circular plate outside the commutator. After this plate has been attached the space between it and the end of the commutator is filled with plaster of paris, and taped on the outside to hold it in place. This style of ring is found to be giving better satisfaction than those of mica and other material formerly employed, as one ring or plate takes the place of the four which were previously used, and which were all threaded. The single ring or plate, with the single thread, is much cheaper and much more readily adjusted than the former.

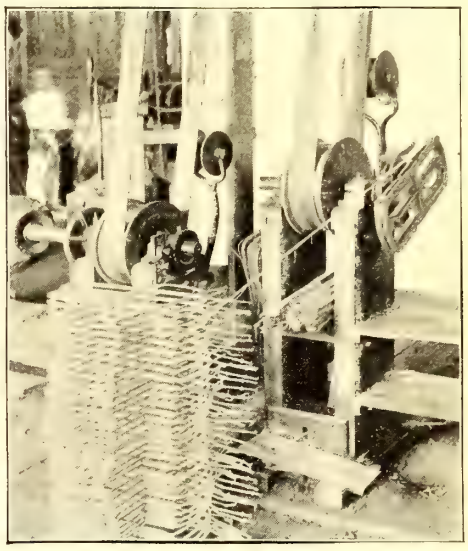
AXLE SLEEVE

The practice has become standard with the Indianapolis Street Railway Company to place a sleeve over the axle from the wheel to the gear to which the motor bearings are attached. For this purpose the axle is turned off to a perfect fit for the entire length, when the sleeves, which are provided with an oil hole at the middle and at each end, are slipped in. This arrangement gives a larger wearing and



bearing surface, and prevents heating, and, it is claimed, makes the axle run as easily, if not more easily, than the short bearing.

GEAR CUTTING MACHINE



It is the practice in the repair shop to cut gears and pinions from cast steel blanks, bought of manufacturers in Cleveland. The gear cutting machines are of the Gould & Eberhardt type, and there is also a milling machine for cutting the slots in the commutator bars, these being milled in after the commutator is completed.

DEVICE FOR TESTING ARMATURES

The accompanying illustration shows a method of testing an armature while it is still in the lathe, either before or after the binding wires have been put on. For this purpose a laminated field is attached to the side of a swinging gate, as shown. This gate consists of a frame work hinged to a post, so that it can be swung out of the way or brought around so that the field is made to embrace the armature while in position in the lathe. A 3500-volt alternating current is then passed through the field, while the armature is slowly revolved in the magnetic field thus produced. By this means any short circuit or inferior insulation is at once detected; for, in case of any imperfection, the wires will give out a buzzing sound and sparks will be noted between the bars of the commutator. The alternating current for testing this device is obtained from a small motor generator, which is operated from the line current. In connection with this method of testing are a bank of incandescent lamps and other features for regulating the resistance.

METHOD OF TESTING ARMATURES

BENDING FORMS

INSULATING MATERIAL

Boiled linseed oil is employed for treating the armature and field coils. This is applied the same as an insulating paint, when the armature and coils are baked until they are thoroughly dry, one or two days being required in the process. The armature oven is heated by means of electric heaters.

BENDING FORMS

The accompanying illustration shows a brass form which is employed in a lathe for making the coils for the General Electric 800 motor. These coils are made in a simple loop on this form, and then are placed in a wooden clamp, shown in the previous illustration next to the armature. Passing through each end of the clamp is a rod of the same diameter as the small loop to be formed in the coil. After the coil is in position, the curved blocks are brought firmly together by means of a set-screw, when the two parts of the coil are bent, one in each direction, and with a mallet are made to conform to the curve in the wooden form. In this way all the coils come out with similar bends and loops, and conform to each other perfectly when placed over the core. In the repair shop three expert armature winders are employed, with three helpers, so that the six hands do all the repairs for the 135 motor equipments employed on the system.

BRASS FOUNDRY

The company manufactures all its own brass parts, including trolley wheels, overhead appliances and car trimmings; it also makes its own babbitt metal. In casting the trolley wheels the patterns are arranged in groups of four, so that four complete wheels are formed in each flask. These are afterwards sawn apart, and trimmed and finished up on a lathe.

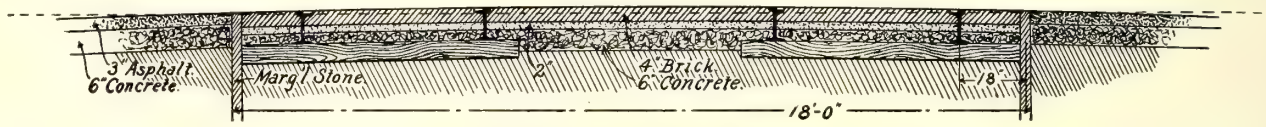
TAPING ARMATURE COILS

For taping armature coils, a machine is used which was illustrated and described in these columns in the May issue, but not all the coils are taped on this machine. The company has in its employ an expert at hand taping. He is a man who was crippled in the service of the company and is now employed in the taping department. He has designed a wooden form which is placed upon a table and which holds the coil in such position that he is able to pass the roll of tape through the loop very rapidly. With rubber tape the folds stick together slightly so that the roll does not unwind readily, but when using canvas strips he cuts up the tape into suitable lengths and winds it on in sections, making proper splices and knowing from experience just how long the strips should be. The objection to using the taping machine, as claimed by this operator, is that the splices in the tape are not detected, and being wound on the coils make an uneven surface.

Iron Rust as an Insulator

While a gang of men were blasting rock on a highway near Rockland, Me., recently, a large ½-in. cable chain, 30 ft. or 40 ft. long, was thrown over a live trolley wire. The wire was broken away from the clip and came down to within 5 ft. or 6 ft. of the track. A bight of the chain lay on the rail and was left in this position for several minutes, without the slightest sign of a short circuit. The chain was taken off the rail by the men, who expected to see some pyrotechnics, but, much to their surprise, there was not the slightest spark from the breaking of the contact, so great was the resistance in the rust on the chain.

The Status of the Indianapolis Street Railway Company



The street railway affairs in Indianapolis, after having been in a very unsettled and unsatisfactory condition for more than six years, owing to litigation between rival companies and between the city and the two street railway companies to whom franchises had been granted, have at last settled down to a satisfactory condition. By an act of Legislature at its last session the way was paved for an amicable adjustment of all the inharmonious conditions, and on April 6, 1899, a new franchise was granted the Indianapolis Street Railway Company, and under the provisions of this document the company has been organized, with the following officers and directors: Hiram P. Wasson, president; Hugh J. McGowan, second vice-president and general manager; J. Augustus Lemke, first vice-president; Joseph S. Neff, third vice-president; W. F. Milholland, treasurer and assistant secretary; Henry Jameson, secretary; C. E. Morgan, 3d assistant secretary and assistant treasurer; directors, Messrs. McGowan, Wasson, Lemke and Jameson, George Brown, Harold B. Hibbard and Randal Morgan.

These officers have assumed control of the street railway affairs of the city.

Under the provision of the act both of the old companies have agreed to surrender all their franchises and rights owned and controlled by them under previous grants from the city and from the County Commissioners and the suburban towns which have now been annexed to the city, and have fully accepted the terms of a new franchise. This franchise is granted for a period of thirty-four years, with the specific statement that the grant is expressly limited to a period of thirty-four years, and must terminate at the expiration of that time; it also requires that the company shall not float any securities to extend beyond the limit of the franchise. One of the provisions of the new franchise is that first-class service shall at all times be provided, and that for the present the overhead electric system shall be employed, but the city reserves the right to compel a change of motive power under the direction of the Board of Public Works and Common Council, provided a superior power shall come into use and be generally adopted in other cities before the expiration of the franchise. There are other stringent measures, which virtually place the company under the direction of the Board of Public Works and the City Engineer.

The new franchise requires that the rate of fare during the period for which the franchise is granted shall be five cents for each passenger over the age of five years, with the right to have transfer privilege over any of the intersecting lines. It also provides that the tickets shall be furnished and sold to passengers by the conductors at the following rates: Six tickets for 25 cents; twenty-five tickets for $1, the transfer privilege going with the tickets as with the cash fare. Some of the further requirements of the franchise are that the company binds itself to pay into the city treasury the sum of $1,160,000 in instalments, which are to be expended for park purposes under the direction of the Public Park Commissioners of the city. The instalments are to be paid as follows: $30,000 on or before the first day of May, 1899, and the sum of $30,000 on or before the first day of May of each year thereafter during the first twenty-seven years of the existence of the franchise; but after the expiration of the twenty-seven years and for the remaining seven years of the existence of the franchise the annual payment is to be $50,000. The above payment is to be in lieu of all license and special taxation, but not to take the place of general taxation. In connection with its property the company binds itself that it will expend, as rapidly as the requirements of the plant and road demand, not less than $1,000,000, and as much more as shall be needed, for adequate and efficient service in buildings, equipment and machinery, and in the purchase of new passenger cars and appliances, as well as new rails and all other necessary materials and labor. The company also binds itself to defend the city and hold the city free and harmless from all damage to any person or persons on account of injury or damage. Another important provision is that the tracks of the company may be used by the suburban lines, so that cars on these lines may reach the center of the city over the company's tracks, under such conditions and at such rental as may be regulated by the Board of Public Works.

Included in the conditions are specifications for lighting, heating and general equipment of the cars in building, life guards, signal buttons, signs and necessary repairs, which can be ordered by the board in case the company fails to keep the rolling stock in good order. The franchise also provides that a sufficient number of cars be operated. Another requirement is that the company shall pave the space between the rails, including the space between the tracks where there are double tracks, and for a distance of 18 ins. on the outside of the outside rails of the track, and shall make all necessary repairs in this space as shall be required by the Board of Public Works, and in connection with this the company is required to keep on deposit to the credit of the Board of Public Works the sum of $1,000, to be known as an emergency fund, and which the board holds the right to use in making immediate and necessary repairs should the company in any way fail to keep this contract regarding paving.

SECTION OF STANDARD TRACK CONSTRUCTION—INDIANAPOLIS

There is also a provision that the company shall execute a bond in the sum of $25,000 to the city, with sufficient securities to insure the faithful performance of the agreements. There are many other important features, but they are too voluminous to be used in this connection. Those interested, however, can get from the city authorities a copy of the franchise, which is known as General Ordinance No. 16, 1899.

Under the paving requirements some of the main streets of the city are at present paved with a combined brick and asphalt surface, and the method of construction is shown in the accompanying illustration. The special features of this are that brick is employed between the rails and tracks for a distance of 18 ins. outside of the outside rail, with a granite border or margin, consisting of a single line of granite blocks placed lengthwise between the brick and the asphalt. This serves to mark a line between the sections for which the city and company are responsible. Brick is also employed in the gutter on each side of the street for a distance of 4 ft. This is to provide a surface that cannot be affected by standing water. The founda-

tions for paved brick and asphalt are to be six inches in depth, as shown in the illustration. The rails shown are of the girder type, but it is understood that in all new construction the city authorities will require the company to use the New York type of grooved rail.

In recent track construction a 62-ft. rail has been employed, with the joints united by the Atlas rail joint, which was the standard with the old company. The track master claims that with this joint he has been able to keep the joints up in better shape than with most any other type of joint used. In attaching these joints to the old rails the old style of fish plates is removed, when the rail is carefully cleaned and the new plates attached. In putting the joint in position the rails are turned up very tight, and the plates are hammered thoroughly with a heavy sledge to bring them to a close fit with the rail. When the new joints are placed, the paving is not finished up until later, or on another day, as it was found that where the plates are tightened up as thoroughly as possible on one day and allowed to remain over night, or for another day or two, another turn may be gotten on the threads. In attaching the new joints to the old rails the old bonds are left when they are found intact, but additional bonds of the horseshoe type are placed in all joints, new holes being drilled in the end of the rails for the purpose.

For riveting the bonds in place a peculiar tool something like a cant hook is employed. This is provided with a bar that reaches the full length of the bond, and which is placed against the head of the bond. This bar is also fitted with a hook, which is attached to the head of the rail, and by pressing down on the long handle a very rigid anvil is provided, so that the lugs are readily riveted in place. By having the heading bar long enough to reach from one lug to another the ends of the rail can be brought well into line, so as to insure proper adjustment when the joint plates are attached.

Most of the special work on the entire system was manufactured by the Indianapolis Frog & Switch Company, and, according to the reports of the track master, is giving excellent satisfaction.

The first order for cars under the new franchise has been given to the American Car Company, and includes twenty-six twelve-seat open cars, which are mounted on double trucks of the Brill maximum traction type. Orders for additional equipment will follow as fast as the needs of the service demand.

The power equipment is also being increased by the installation of a direct-coupled unit, consisting of an Allis engine and a 500-kw. Westinghouse generator. The boiler room is also being enlarged, and two additional boilers of the Babcock & Wilcox type are being installed. In connection with boiler house improvements coal handling devices and conveyors will be installed, and probably some type of smokeless furnaces. For a number of years natural gas has been employed as fuel, but coal is now used. It is interesting to know that some of the Short generators which were installed at the early application of electric power on these lines, and described in our issue of August, 1894, are still running and giving reasonable satisfaction.

It can be shown that the only benefit received by the companies for carrying the mails on street and interurban railways is the compensation allowed by the Government for the same; hence the railways should work with the end in view to make this compensation enough to justify them in looking upon the carrying of mails as a profitable business, and one which should receive their careful attention. From paper at the Boston Convention, 1898.

Overhead Line Construction, III

BY ALBERT B. HERRICK

PROPORTIONING FEEDERS

After the current for the feeders has been determined, as described last month, the next question is the location of the feeding sections and the proper disposition of the copper in order to get maximum potential delivery. This copper may be in one or several feeders. Where it is combined into one feeder the cost of copper, per volt drop, is least. The cost of supporting this feeder is less, and the strains which it imposes on the pole line and the surface it presents to wind pressure, are all in favor of the single feeder. The sub-division of the feeders and the connection of these separate divisions to different circuit breakers in the station is for safety. The sub-division of the feeders may be said to have been originally due to the employment of fuses as safety devices. The action of the fuse required the dividing of the feeding systems up into small independently fed sections, but the modern circuit breaker, being much more prompt in its action, provides ample safety for the electrical machinery. Fuses, if placed between separate feeders on the line, will open when any section is grounded, so that in rewiring or reconstructing old distribution systems it is desirable to inter-connect the neighboring feeders by fuses, and thus get the most effective use of the copper.

In determining the size of feeder it is necessary to first fix upon the voltage drop, the amount of current required and the distance from the station. If the former has been selected the product of the other two gives the distance of current demand, since the ampere feet with a fixed drop for each size conductor has a certain value. The practical application of this to a railway problem will now be considered. It is usually most convenient to locate the feeding points about 500 ft. apart, then the current taken at the first point located, multiplied by the distance of its location to the station, will be the ampere feet at that point. Each point along the road can be located, and ordinates erected to some scale of ampere feet, until the whole road is graphically laid out by these ordinates. The current consumed can be found by the use of the table in the July number of the JOURNAL.

The diagram on page 514 shows the application of this principle of locating feeders to a road 16,500 ft. long, on which the cars are 500 ft. apart with a 12 per cent. drop; ordinates are drawn every 500 ft. or for each car, and their length represents the ampere feet required at each point. To apply this diagram to the case of a road with cars a greater or less distance apart the ampere feet required will be inversely proportional to the car spacing; thus with cars 3000 ft. apart the values in ampere feet will be one-sixth of the values given in the diagram. A column of ampere feet is given in column 15 in the table on the inset, from which the different conductors can be readily selected and applied to find the least feeder cost for this distribution.

It will be seen from this diagram that the feeding sections grow smaller as the distance increases from the station, so also this method of laying out feeders gives each feeder uniform service. The limiting distances for No. 0, No. 00 and 000 feeders, applied to the problem worked out are shown in the diagram. The ordinates below the date line show the current consumed by the cars at each point. This current, multiplied by the distance from the station, gives the ordinates above the date line, which are the ampere feet. With a road in which the feeders traverse short cuts, the problem would have to be arranged so that the distribution takes place from the intersection of the

feeder and trolley, and the distance in feet to the station from this point, would be the feeder length.

The table on the inset page shows all the dimensions of copper wire, and their electrical and mechanical properties, from 1,000,000 c.m. No. 1, B. & S.

The first column of this table gives the diameter of the wire in thousandths of an inch and B. & S. gage.

The second column gives the area of wire in c.m.

The third column gives the outside diameter of the stranded conductors.

The fourth column gives the outside diameter of the triple braided weather proof wire in nearest thirty-seconds of an inch.

The fifth column gives the weight per thousand feet of conductor.

The sixth column gives the weight of triple braided weatherproof per mile of conductor.

The seventh column gives the weight of the bare copper.

The eighth column gives the usual per centage of weight of insulation to total conductor weight.

The ninth column gives the stranding of conductors, as usually employed.

The tenth column gives the breaking strain of these conductors. One-sixth of this should be used for the line strains.

The eleventh column gives the resistance per thousand feet in international ohms at 60 degs. F.

The twelfth column gives the resistance in international ohms per mile 60 degs. F.

The thirteenth column gives the number of feet the wire will carry its full current carrying capacity with 12 per cent drop, 500 volts.

The fourteenth column gives the current carrying capacity of this wire as given by the Underwriter's rules for suspended wire in open air.

The fifteenth column gives ampere feet capacity of conductor with 12 per cent drop.

The sixteenth column gives the weight of wire between 100-ft. spans.

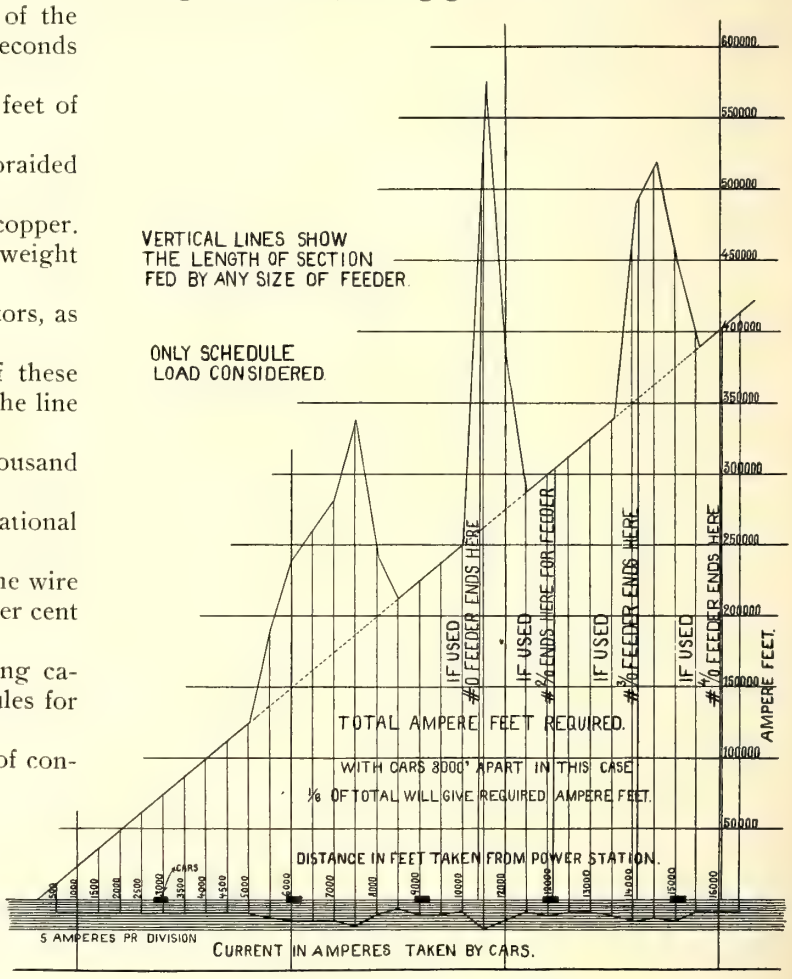
The seventeenth column gives the wind area in square feet presented by each size wire, triple braided 100-ft span.

It will be seen from the table of the weight of wire insulated, that for a dollar in the larger size cables we get more conductivity, since the ratio of the weight of the covering to the weight of the copper grows as the diameter of the wire decreases.

WIRING DIAGRAM FOR SIMPLE TRANSMISSION

Below this table is a diagram from which the correct size of wire to use in power transmission can be determined, from a distance of 1000 ft. to 25,000 ft., and from no drop to 200 volts drop. On the lower margin of this table will be found current in amperes. On the right vertical edge will be found distance in feet. On the left vertical edge will be found volts drop. On the top of the sheet will be found sizes of wire, with a heavy line vertically through the table for for each size of wire.

Any wiring problem within the values given on the diagram can be solved as follows: Suppose we had 200 amps. to carry three miles with 50 volts drop Start at the bottom of the diagram at 200 amps., follow this vertical line up until it intersects the horizontal line from 50 volts on the left hand vertical scale, pass along the radial line from this point until the horizontal line from 3 miles is met. The vertical line passing through at this point will lead upwards until the scale of wire in circular mils is reached, and this will be 67,500 c.m., the value sought. Any three terms of railroad feeder being known the fourth can be determined graphically by this table. For instance, suppose we had 0000 wire and wished to find out how far this would take 100 amps. with 75 volts drop. This problem can be solved by finding the intersection of the 100 amps. and 75 volts lines and passing along the radial line intersecting this point until the vertical line extending from the c.m. scale from 0000 wire is reached. Then the horizontal line intersecting at this point from the scale of feet will give the distance in feet that the current can be carried with this wire and with this loss. The problem of finding the current, having given distance, size wire, and



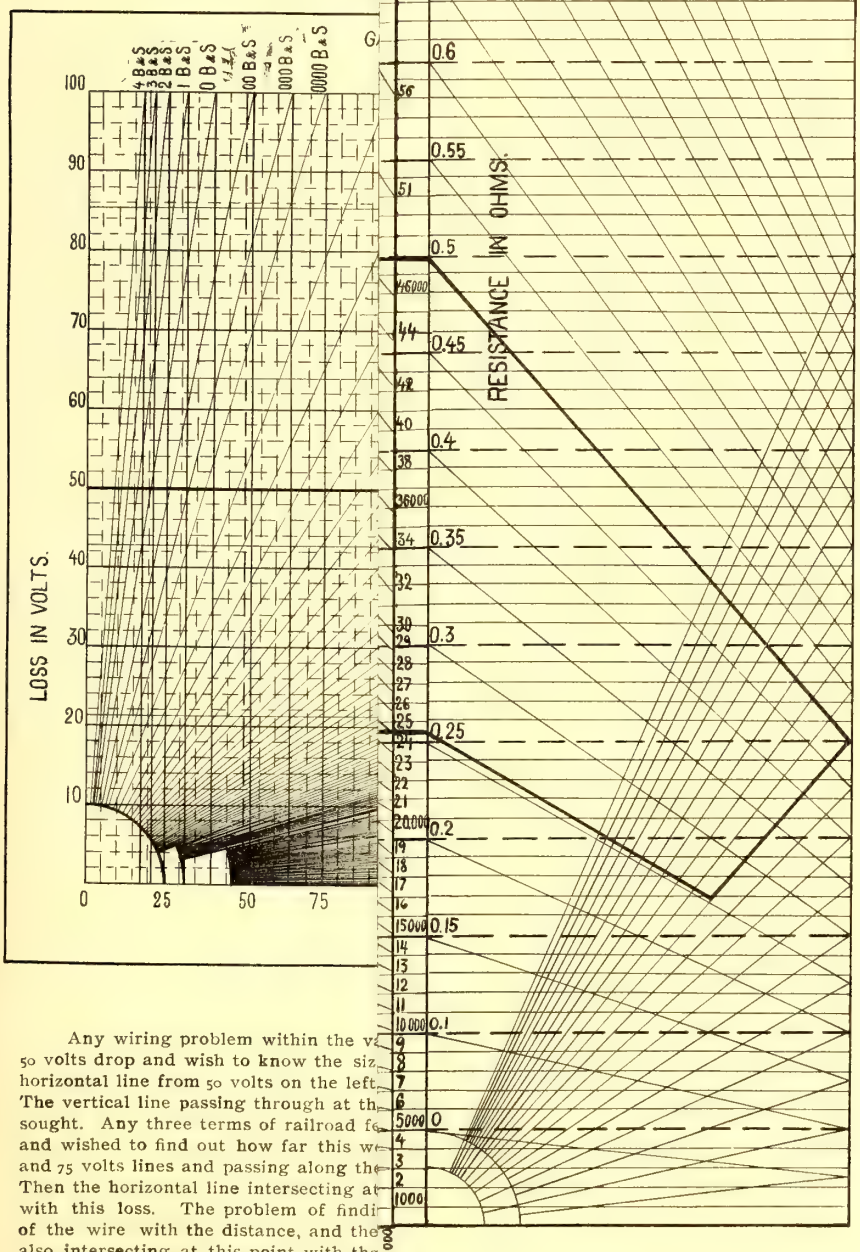


DIAGRAM FOR LOCATING FEEDERS

drop, can be solved as follows: First, find the intersection of the wire with the distance, and then pass along the radial line intersecting at this point until the volts drop is reached. Then the vertical line also intersecting at this point with the radial drop line will lead to a horizontal scale in amperes and satisfy the other conditions of this equation. The other required problem, to find the volts drop when the size of wire, current and distance are given, can be worked out in the same way. The conductor length is given in feet single distance and the table should not be used for a metallic circuit; for in that case it shows only half the amount of copper necessary.

MULTIPLE FEEDING

Another problem that often arises in railway feeders is to find the multiple feeding resistance of several conductors when the current is delivered at one point. The rule for this is to multiply together two resistances, and divide their product by the sum of their resistances. If another conductor is feeding in multiple with these two and the correct resistance of these three conductors in multiple is sought, the combined resistance of the first two must first be determined, and then combined with the third conductor in the same way. This soon becomes a very involved problem if a number of conductors are considered feeding

EEDING DIAGRAM

To find the combined resistance of two conductors, the length and size of which are given, follow along the curved line branching from the given length in feet, until it intersects the vertical line indicating the proper size. Then follow the horizontal line at this intersection to the resistance scale. Locate, in the same way, the resistance of the other conductor in multiple with this. Then follow the diagonal line from the highest resistance conductor to the deflector line at the extreme right, then pass along this same line towards the resistance scale until the diagonal line from the lower resistance conductor is reached. Opposite this point of intersection can then be read the resistance of the two conductors in multiple. This multiple resistance can then be used as a single conductor resistance and the resistance of another conductor in multiple with this can be determined by the same method. As an example suppose we had a No. 0 trolley, feeding 5000 ft. in multiple with the No. 0000 feeder of the same length. Follow along the 0 line until the curved line from 5000 ft. is reached; the value on the resistance scale will be .5 of an ohm. Then follow along the 0000 feeder until 5000 ft. is reached, and the reading on the resistance scale will be found to be .25 of an ohm. Pass along the diagonal line from the higher of these two resistances, and continue along this line after it has changed its direction until it has intersected the lower diagonal line from the 0000 feeder resistance. From the point of intersection follow back the horizontal line to the resistance scale and the reading there will be the combined resistance of these two conductors, viz: .17 of an ohm.

DIAGRAM OF WIRING FOR SIMPLE TRANSMISSION

Compiled by Albert B. Herrick

Any wiring problem within the values given on the above diagram can be solved as follows: Suppose we had 200 amps. to carry three miles with 50 volts drop and wish to know the size of wire. Start at the bottom of the diagram at 200 amps., follow this vertical line up until it intersects the horizontal line from 50 volts on the left hand vertical scale, pass along the radial line from this point until the horizontal line from three miles is met. The vertical line passing through at this point will lead upwards until the scale of wire in circular mils is reached, and this will be 67,500 c.m., the value sought. Any three terms of railroad feeder being known the fourth can be determined graphically by this table. For instance, suppose we had 0000 wire and wished to find out how far this would take 100 amps with 75 volts drop. This problem can be solved by finding the intersection of the 100 amps. and 75 volts lines and passing along the radial line intersecting this point until the vertical line extending from the c m. scale from 0000 wire is reached. Then the horizontal line intersecting at this point from the scale of feet will give the distance in feet that the current can be carried with this wire and with this loss. The problem of finding the current, having given distance, size wire, and drop, can be solved as follows. First, find the intersection of the wire with the distance, and then pass along the radial line intersecting at this point until the volts drop is reached. Then the vertical line also intersecting at this point with the radial line will lead to a horizontal scale in amperes and satisfy the other conditions of this equation. The other required problem to find the volts drop when the size of wire, current and distance are given, can be worked out in the same way. The conductor length is given in feet single distance and the table should not be used for a metallic circuit; for in that case it shows only half the amount of copper necessary.

MULTIPLE FEEDING DIAGRAM

To find the combined resistance of two conductors, the length and size of which are given, follow along the curved line branching from the given length in feet, until it intersects the vertical line indicating the proper size. Then follow the horizontal line at this intersection to the resistance scale. Locate, in the same way, the resistance of the other conductor in multiple with this. Then follow the diagonal line from the highest resistance conductor to the deflector line at the extreme right, then pass along this same line towards the resistance scale until the diagonal line from the lower resistance conductor is reached. Opposite this point of intersection can then be read the resistance of the two conductors in multiple. This multiple resistance can then be used as a single conductor resistance and the resistance of another conductor in multiple with this can be determined by the same method. As an example suppose we had a No. 0 trolley feeding 5000 ft. in multiple with the No. 0000 feeder of the same length. Follow along the 0 line until the curved line from 5000 ft. is reached; the value on the resistance scale will be .5 of an ohm. Then follow along the 0000 feeder until 5000 ft. is reached, and the reading on the resistance scale will be found to be .26 of an ohm. Pass along the diagonal line from the higher of these two resistances, and continue along this line after it has changed its direction until it has intersected the lower diagonal line from the 0000 feeder resistance. From the point of intersection follow back the horizontal line to the resistance scale and the reading there will be the combined resistance of these two conductors, viz. .17 of an ohm.

Copyrighted, 1899, by the Street Railway Publishing Company.

in multiple arc. In order to facilitate the calculation of the railway engineer another chart is given at the right of that previously described, which graphically solves these problems of the resistance of conductors in multiple. The heavy vertical line near the centre of the chart is laid out on one side to a scale in feet, and on the other side to resistances. In order to find the combined resistance of two conductors, the length and size of which are given, follow along the curved line branching from the given length in feet, until it intersects the vertical line indicating the proper size. Then follow the horizontal line at this intersection to the resistance scale. Locate, in the same way, the resistance of the other conductor in multiple with this. Then follow the diagonal line from the highest resistance conductor to the deflector line at the extreme right, then pass along this same line towards the resistance scale until the diagonal line from the lower resistance conductor is reached. Opposite this point of intersection can then be read the resistance of the two conductors in multiple. This multiple resistance can then be used as a single conductor resistance and the resistance of another conductor in multiple with this can be determined by the same method.

As an example, suppose we had a No. 0 trolley feeding 5000 ft. in multiple with the No. 0000 feeder of the same length. Follow along the 0 line until the curved line from 5000 ft. is reached; the value on the resistance scale will be .5 of an ohm. Then follow along the 0000 feeder until 5000 ft. is reached, and the reading on the resistance scale will be found to be .26 of an ohm. Pass along the diagonal line from the higher of these two resistances, and continue along this line after it has changed its direction until it has intersected the lower diagonal line from the 0000 feeder resistance. From the point of intersection follow back the horizontal line to the resistance scale and the reading there will be the combined resistance of these two conductors, viz: .17 of an ohm.

Growth of the Electric Railway Industry in Europe

According to a recent monthly bulletin of the Compagnie Francaise pour l'Exploitation des Procédés Thomson-Houston, at Paris, the first electric railway in Europe was built by the Siemens-Halske Company, in 1881, between Lichterfeld, near Berlin, and the Central Military Establishment. In 1889, the first electric railway in France was built with Thury apparatus at Clermont-Ferrand, this tramway being still working. In the same year, 1889, at the Paris Exposition, the French Thomson-Houston Company first showed electric railway apparatus, of which exploitation had already commenced in America, and this exhibit was awarded the grand prize, while at the same time Prof. Elihu Thomson was made an officer of the National Order of the Legion of Honor. The first actual railway of the Thomson-Houston system was built in December, 1893, from Bordeaux-Bouscat to Vigean. To-day there are 11,000 kilometers operating by the Thomson-Houston system in France and 21,000 in the rest of Europe, or 32,000 in all. On these 32,000 km. of track about 7800 cars are run, of which 5800 are motor cars and 2000 trail cars. The current is furnished by 50,000 kilowatts of generator capacity.

After a number of trials of various floor paints and paints mixed especially for the purpose, the conclusion has been reached that there is nothing equal to pure white lead and linseed oil and suitable color for the floors of all cars. From paper at the Boston Convention, 1898.

Comparative Gross Receipts of American Street Railway Companies

In the following table are presented the comparative gross receipts of 222 American street railway companies for financial years ending (at various times) in 1897 and 1898, and the percentage increase or decrease in the two years. Classification is made on the basis of gross receipts in 1898, as the magnitude of operation is, of course, the interesting feature of a comparative presentation of this character. The details may be summarized as follows:

Roads having gross receipts of—	Number	Gross Receipts: 1897	1898	Percentage Inc.
$1,000,000 or more	26	$90,035,454	$93,740,164	4.1
500,000 to $1,000,000	20	13,685,777	14,407,780	5.3
100,000 to $500,000	58	12,634,697	13,389,776	6.0
50,000 to $100,000	62	4,237,941	4,414,039	4.2
25,000 to $50,000	56	2,019,385	2,130,762	5.5

The per cent increase in gross is seen to be uniform in the different classifications, but with wide variation in individual cases. In New York City the Metropolitan system shows an increase of 7.7 per cent, the Manhattan elevated system a decrease of 5.4 per cent, and the Third Avenue system a decrease of 9.6 per cent, while the receipts of the Union Railway Company, above the Harlem, increased 13 per cent. The Brooklyn Rapid Transit Company, both surface and elevated systems, made the very surprising increase of 17.5 per cent for the year ending Dec. 31, 1898, over the year ending June 30, 1897, and along with this came an increase of 23.8 per cent in the gross receipts of the Coney Island & Brooklyn Railroad Company, the only company competing with the Rapid Transit combination.

Seattle, Wash., has had apparently an exceptionally prosperous year, the gross receipts of the Seattle Traction Company having increased 54.9 per cent, while those of the West Street & North End Electric Railway Company, of Seattle, have increased 59.4 per cent.

Many of the suburban roads around Boston show large increases, among them the Norfolk Central Railway Company, 120.8 per cent; the Framingham Union, 52.6 per cent; the Newton & Boston, 48.7 per cent; the Commonwealth Avenue, 34.9 per cent, and the West Roxbury & Roslindale, 32.3 per cent. Several other interurban roads in Eastern Massachusetts, however, show decreases, among them being the Union Street Railway Company, of New Bedford, with its associated company, the Dartmouth & Westport Street Railway Company, the Haverhill & Amesbury, 9.9 per cent; the Taunton, 13.4 per cent; the Dighton, Somerset & Swansea, 12.2 per cent, and others.

Among other companies which show large percentage increases may be mentioned the system of New Castle, Pa., 217.8 per cent; Nashville, Tenn., 47.4 per cent; New Brunswick, N. J., 44 and 54 per cent respectively; Warren, Brookfield & Spencer, 43.2 per cent, and Chicago General Railway Company, 50 per cent.

ROADS HAVING GROSS RECEIPTS FOR 1898 OF $1,000,000 OR OVER

Name of Company	Gross Receipts, 1897	Gross Receipts, 1898	Per Cent Increase

Convenient Rheostat for Testing

For carrying large currents while testing in a power station or repair shop, a water rheostat made out of an old barrel is a common form of resistance employed. There are some disadvantages in connection with its use, however, especially the difficulty of keeping the ohmic resistance of the rheostat any way constant.

A different form of cheap rheostat is employed by the engineers of the Consolidated Traction Company of Pittsburgh, in the new power station at Twentieth Street and the Allegheny River. It consists of about 300 ft. of No. 12 bare copper wire, wound upon a wooden frame, and then immersed in an ordinary oil barrel filled with water. This wire will carry about 225 amps. (at 550 volts) if cold water is kept running continuously through the barrel. A ½-in. hose will usually supply enough water to keep the rheostat cool. At the Consolidated station there are ten of these rheostats, and they have been found very satisfactory.

Plows for Underground Conduit Electric Cars

Although a considerable item of expense was abolished when the overhead trolley went out of use, the trouble and outlay has probably been at least equalled, if not increased, by the care and expense incident to the use of the underground current.

The plow, although the result of a great deal of engineering talent outlay, is still far from being practically perfect. Even though suspended in a very elastic manner from the truck of a car, it is knocked and battered to pieces frequently. The present method of elastic suspension is from two 2½-in. round iron or steel bars, which in turn are carried by a light, yet stiff angle-steel frame attached to the end of a (double) truck by means of steel plates, which are bolted to both frame and truck. The plow is attached to a pivoted bar, which in turn is swiveled to shoes that slide easily over the round bars the entire width of a car. The shoes slide very easily, so easily in fact that it seems almost impossible that the plow can fail to respond to demands from the slot, yet it often does fail, and the plow which has been in use for several weeks bears many marks of extra hard usage.

The plows used with cable cars of the New York companies take the slot wear on the steel plates or bars which form the vertical supports of the grip and its mechanism. The life of these frame bars or plates averages about six weeks, when they are removed, being found worn nearly half in two, and are replaced by new bars. In the electric plows, the wear does not come directly upon the bars which support the plows. Instead, four soft malleable iron shoes are attached in pairs to opposite sides of the shoe support or frame. These "chafing plates" are held on by slight recesses in either side of the shoe, and by two countersunk units through the frame and each pair of plates which are located at the line of the slot. In practice, a set of these plates is found to last about three days. Then, the rivets must be chipped out by a round-nosed cold chisel, forged round and tapering, and ground on one side only, at an angle of about 60 degs.

At the lower ends the plows have loose spring contacts which are arranged on a wooden support, which in turn is dovetailed to the lower end of the iron portion of the plow. A piece of thin rainbow packing is cemented to each piece of wood, and the pair when fitted together over the plow frame is firmly fastened together by common wood screws.

The leads which run down through the plows are made of a number of wires, about No. 20 or 22, and braided into a flat tape about ⅝ in. wide. Frequently the wooden portion of a plow gets caught in the conduit and is torn off, the leads being broken just below their exit from the iron portion of the plow. The splicing of these leads is done by sandpapering the broken end until clean and bright. The wire ends of another piece of braided lead are then straightened for about 2 ins., and in alternate bunches of half a dozen, are bent back and forth to form a sort of Y into which the broken lead end is placed. The wires of the new piece are then bent down upon the old piece, bound with a narrow strip (¼ in. wide) of thin tinned copper and hammered flat. The joint is then soldered, alcohol and resin being used as a flux, after which the thin copper is stripped off and the splice filed a little and taped.

Testing, for continuity of leads and for grounds in the plows, is done by a couple of contacts rigged on long flexible wires in the usual manner and connected with a 500-volt current through five lamps in series. While it is usual to throw such contacts carelessly aside when not in use, it is the practice by at least one man in the Metropolitan shops to use his bank of test lamps for light. The test

points were thrust under the free ends of a strip of copper, which in turn was fastened by two screws through its middle portion, to a piece of slate. When it is necessary to test, the wires are pulled out from under the copper and applied to the work. There is no danger from fire from these testing points.

A Quick Piece of Electrical Equipment

The State Street line of the Chicago City Railway is now being operated by electric power, and the change was made from cable to electricity in three weeks. The ordinance allowing the temporary change was passed on June 19; permit to work on the streets was secured on the evening of the 23d, when work was immediately begun, and the first car was run on the evening of July 15, between 4 and 5 o'clock. The change embraced 7 miles of street on which poles had to be erected, the trolley and feed wires strung, additional power provided and a large number of extra cars to be electrically equipped. The 600 h.p. motor that was formerly employed at Fifty-second Street for driving the cable drums was moved to the Twentieth Street station, where it is operated as a generator during the hours of heavy traffic. Two feed wires were brought over from the Clark Street line and connected with the switchboard of the Twentieth Street station. The ordinance granting the privilege of operating for the present by electric power is for ninety days only, and does not allow the cars to be electrically operated north of Van Buren Street, but between Van Buren and Madison Streets horse cars are run every two and one-half minutes.

The grant was secured for the purpose of making repairs to the Twentieth Street power station, as some of the engines, and especially foundations, were so weakened by long service that a break-down was imminent. The No. 1 and No. 2 Wheelock engines of this station have been in continuous operation, driving the cable plant since 1882, and of late years have been greatly overloaded. The new equipment has not been fully decided upon, but will probably include new engines for those worn out, and new cylinders for the other four engines. The gripmen are operating the electric cars, having been broken in preparatory to the change. It should be noted in connection with the change that all the material had been secured and was on hand ready for immediate use. The change from cable to electric power is very acceptable to the patrons, as the time for making the entire trip is very much reduced.

A New Power Plant for Atlanta

The Atlanta Railway & Power Company has prepared plans for the construction of a modern power and lighting plant, to cost about $750,000. This plant will furnish all the power for the consolidated street railway lines and for general commercial purposes throughout the city, and a lighting service will also be given in competition with the existing company. Steam heat in winter and cold air in summer will be furnished to the large buildings in the business district. The plant is to be centrally located and will be built on a railroad, so that coal can be brought by cars direct to the storage bins. After the new station is completed the present plant in the outskirts of the city will be used for manufacturing street cars for the company and for other street railway companies in the South.

The Broad Ripple Traction Company, of Indianapolis, has been incorporated, with a capital of $100,000, as successor to the Indianapolis & Broad Ripple Rapid Transit Company.

German Track Specifications

A prominent German track engineer has sent us the following specifications for a tramway track, as used in Germany. As will be seen, they differ somewhat from what would be considered standard American practice.

A.—GENERAL REMARKS

The roadbed of an electric railway should be so substantial that it will carry the heaviest traffic. The cost of preparing rail joints and renewing tracks and rails in the city streets is so expensive that no reasonable precautions should be spared in making the weight of rail, quality of material or joint construction as good as possible. In this particular the maxim will be found true as much or more than in any other branch of tramway work, that it "pays to use the best." The track should be so laid as not to hinder the street traffic or interfere with the proper drainage of the street, and the head and flange of the rail should be so designed that uneven wear from street or vehicle traffic will be avoided. The style of pavement in which the track is laid has a considerable influence upon the most desirable height of the rail and the width of the base. Only in asphalt can considerable liberty be exercised in selecting the rail sections, as with this pavement there is comparatively little objection to projecting bolts, wide base, etc. The length of rail should be as great as possible. At present there is no difficulty in rolling rails 12 m. long, even in the heaviest sections. The section should be designed so as to bring the center of support as nearly as possible under the center of pressure. With the composite rail this condition is obtained in an almost ideal way. The single web rail can never be constructed so as to absolutely accomplish this result, as the vehicular traffic will keep on the flange, although the car wheels may be directly over the web.

The heaviest angle plates should be used, and all shock at the joints should be reduced by laying the ends of the rails close together, and, in general, by using the mitered joint. In asphalt paving the rails can be butted, as the rails are held rigidly by the pavement; but in block paving a space should be left for expansion and contraction, though this space should be less than that on exposed track. The tie rods also need not be so numerous in asphalt construction, and, as a usual thing, only about half as many should be used as when the rails are laid in block pavements.

B.—DETAILS OF RAIL SECTION.

1. Rail Head.—The width of the rail must correspond to that of the wheel tread, and should therefore be at least 50 mm. wide. The shape of its surface must correspond to that of the wheels. Where the mitered joint is used the angle plates must be bolted up tight to get satisfactory results.

2. The Groove.—With single web rails the lip of the rail is integral with the rest of the rail, while composite rails are composed of two girders. The depth of the groove with single web rails is limited by rolling mill considerations, but rail makers can now provide, without any trouble, a groove 40 mm. in depth; with composite rails the groove can be made any depth. It is to the interest of the public to have the groove as narrow as possible, and 30 mm. may be considered standard width.

For heavy traffic (ninety cars per hour) the wear of a 50 mm. wide steel rail head, made of the best material, is supposed to be 1.5 mm. per annum, so that for a ten years' life of rails the depth of the throat should equal 15 mm. plus the depth of the wheel flange, or 13 mm. to 15 mm.; total, 28 mm. to 30 mm.

3. The Shape of the Groove.—This should be angular and considerably wider than the wheel flange, to prevent the crowding of dirt and snow into the groove. The wheel flange should be able to press the dirt upward over the lip. The width of the tram (or flat surface of the lip), the part on which street vehicles will run, should amount to at most one-third of the width of the head of the rail, and generally 15 mm. is sufficient if the rail is elevated slightly above the grade of the street. Here unfortunately track engineers are not given much choice, for the authorities frequently demand a much wider tram; for instance, at Berlin, 25 mm.

4. Thickness of the Web.—While with the composite rail 8 mm. is usually a sufficient width of rail web, with a single web rail the web should have the thickness of 10 mm. With an eccentric web rail the thickness of the web should be 16 mm.

5. Base of Rails.—This should not be less than 100 mm. for horse-car rails and 130 mm. for electric rails. The base should have a thickness at the web of at least 20 mm. This thickness may taper down at the ends to 10 mm.

STREET RAILWAY JOURNAL

AUGUST, 1899.

PUBLISHED MONTHLY BY

THE STREET RAILWAY PUBLISHING COMPANY

MAIN OFFICE:
NEW YORK, BEARD BUILDING, 120 LIBERTY STREET.

BRANCH OFFICES:

CHICAGO.....Monadnock Block.
PHILADELPHIA.....929 Chestnut Street.

NOTICE.

Papers and correspondence on all subjects of practical interest to our readers are cordially invited. Our columns are always open for the discussion of problems of operation, construction, engineering, accounting, finance and invention.

Special effort will be made to answer promptly, and without charge, any reasonable request for information which may be received from our readers and advertisers, answers being given through the columns of the JOURNAL *when of general interest, otherwise by letter.*

Street railway news and all information regarding changes of officers, new equipment, extensions, financial changes, etc., will be greatly appreciated for use in our Directory, our Financial Supplement, or our news columns.

All matters intended for publication in the current issues must be received at our office not later than the twenty-second of each month.

Address all communications to

The Street Railway Publishing Co.,
Beard Building, 120 Liberty Street, New York.

We are pleased to note the incorporation in Great Britain of the Tramways and Light Railways Association, an organization similar in scope and purpose to the American Street Railway Association, and with a function quite as valuable, no doubt, as that which the great American Association has for so many years fulfilled. The new association is fathered by excellent men widely known in the industry, both at home and abroad, the six first members of the council being George Richardson, George F. Fry, Emile Garcke, J. Barber Glenn, W. M. Murphy and Stephen Sellon. The honorary secretary is A. M. Willcox, editor of the "Railway World." We sincerely wish our friends across the water the highest measure of success in their organization.

Graphical methods of solving engineering problems are always convenient and usually a time saver to the engineer or worker in the electrical field. For this reason we call attention to the application of "graphics" to the proportioning of feeders, as contained in an article with inset sheet, published elsewhere in this number, and think that the ingenious methods adopted, based, as they are, upon correct geometrical principles, will commend their use to our readers.

A careful study instituted to determine the cause of flat wheels on the North Jersey Street Railway recently has brought to light the interesting fact that the rear wheels, particularly of double truck cars, are more subject to flattening than the forward wheels. The argument adduced to explain this is that when the brake shoes are applied, the tendency of the truck is to rock forward, bringing greater weight on the forward wheels and less on the rear wheels. As the brake rigging is arranged to produce an equal tension on both wheels, the rear wheel develops a tendency to slide before the forward wheel, and this is thought to produce the flattening. An effort is being made to reduce this by so changing the brake leverage that a difference in pressure is exerted by the two sets of brake shoes, corresponding to the difference in weight carried by each pair of wheels. The outcome of this test will be watched with interest.

The striking difference between European and American track construction is shown in a set of track specifications by a prominent German engineer, which is published elsewhere in this issue. It seems somewhat amusing to American readers to be told that the rolling mills have now no difficulty in producing rails 39 ft. long, and that in asphalt paving the rails can be butted, but that in block paving a space should be left for expansion and contraction. It is also contrary to the best American practice to lay rails in asphalt without a stone setting, while the frequent reference to composite rails, and rails with eccentric web and mitred joints, seems strange to American readers. Undoubtedly several of the differences in practice, such as the eccentric web rail and the composite rail, are due to differences in conditions. While the former rail undoubtedly possesses certain advantages from a structural standpoint, the cost of milling the rail ends will undoubtedly preclude its general use in this country, with present prices of labor, but this expense may not be as great in Europe. The composite rail has been tried to a limited extent only in this country, and perhaps under such unfavorable conditions that its true value has not been determined by American managers, but the sentiment in this country at present is practically unanimous in favor of a single web rail. Certain other conditions must undoubtedly be attributed to differences in the weight of cars, the European cars being, as a rule, much lighter and smaller. The tendency will grow, we think, however, in European countries towards the employment of longer and heavier cars, although the labor charge being lower, there is not the same incentive to the use of long cars in Europe as in America. In other respects we look for a modification of the European practice in track building, tending towards the American grooved rail construction; and while municipal councils abroad seem unalterably opposed to any section of head similar to

the American standard girder rail, we should think that the Metropolitan or Crimmins' rail would admirably suit the conditions existing in European cities.

There is grave danger that the strong hold upon the export trade in a hundred different industries which American manufacturers have obtained during the past five years will be loosened, if not destroyed, this year and next, by lack of foresight or sheer carelessness, either or both. The home demand for manufactured product has suddenly become so almost overwhelming, and profits immediately in sight seem to be so great, that the foreign demand is being in many cases neglected, and foreign agencies, which have been doing such magnificent work, and which are worthy of all support, are being "starved out" through refusal of home manufacturers to fill orders except at practically prohibitive prices. The wisest of our manufacturers are not, it is true, falling into this mistake, but mindful of the possibly temporary character of the home trade, are continuing to help out the foreign agencies in their endeavor to secure the wide and varied world market, which ought to be far more permanent in character than that of any one country, however rich and prosperous. But too many of the smaller manufacturers are "spasmodic" in their effort to enter the foreign field, and will find it extremely hard to take up the lines again and renew old friendships when the necessity for foreign outlets again comes upon them.

The foreign customer in almost all branches of trade is a very different being from the American. The British people, home and colonial, are attracted by age and persistence in business dealings, and despise weak and ill-sustained effort. They are not constantly seeking lower prices, but will often deal for a score of years with long established houses with which they have a *habit* of dealing. With them confidence once lost is never regained. Continental Europe buys in America, not because it wishes to do so—only because it has to. Any excuse which a customer can find for failure to place orders in America will be availed of. The South American trade has always belonged chiefly to Great Britain, though partly to Germany and France. Latterly, pro-American feeling has been largely developed in many of the South American countries, and it needs only a little cultivation to build up an important and constantly increasing market for American goods. Elsewhere in the purchasing countries of the world American goods have come to be highly regarded for their intrinsic value and a new trade is partly worked up. This ought not now to be lost through carelessness or neglect, even when home profits are more tempting.

There is every reason in the world why America should become the great manufacturing nation of the world. With limitless natural resources in coal and ores; with unequaled internal and external transportation facilities, natural and created; with unsurpassed organizing ability for the creation of vast industries and the handling of labor; and with labor itself skilful, intelligent, well fed and well treated for a hundred years past, our manufacturers may safely expand their facilities to meet the present home demand, and a future foreign demand enormously greater than which exists to-day.

In a lengthy argument in favor of the municipal control of street railways, which appeared in one of the New York dailys recently, great stress was laid upon the economic value of the fact that municipalities can borrow money at very low interest, and that consequently they could afford to operate street railways at much lower rates than could a private corporation. This is an old and favorite argument which seems, from a superficial view, to be sound, but a little further consideration will show that it is not such a good argument in favor of municipal control as would first appear. The people who lend money to municipalities do not accept low rates in interest from sentimental grounds, but because the security is better than that which a private corporation can give. The municipality is practically an unlimited corporation, made up by the different taxpayers, and the security given or pledged to make good the loan is their property. Now if, with private ownership, a railway should be uneconomically administered, or if, even with excellent management and the best human foresight, the line should prove unprofitable and the company fail, the loss does not come upon the residents of the city. On the other hand, however, if under municipal operation a similar trouble should be encountered, the citizens have to make up the deficiency. That is, the real property of all kinds belonging to the taxpayers is pledged as security for the wisdom and ability of municipal officers as railway managers. The taxpayers pay the bill if anything goes wrong. Moreover, any possible saving in interest account will be far more than counterbalanced by the large increase in cost of labor sure to come with municipal ownership, since one thing which the advocates of municipal ownership always promise to do is to increase the wages of labor or reduce the hours of work, which amounts to the same thing. In fact, one of the laughable features of municipal ownership arguments as usually advanced is that "you can eat your cake, and have it, too," i. e., you can reduce fares, increase wages of labor and make more money for the city's treasury—all at the same time.

We believe that Mr. Duffy and Mr. Ham were, on the whole, justified in yielding to the unanimous wish of the committees representing the Associations of Railroad Commissioners and of Railroad Accountants that "taxes" should be included in "deductions from income," instead of made a part of "operating expenses," though the latter classification was decided upon by the committee on standardization of accounts of the Street Railway Accountants' Association of America. It is best that railroad accounting practice should first be made uniform, and then should be corrected "from the inside," as it were, wherever corrections are right and necessary. We believe that taxes belong in operating expenses, in spite of the almost universal accounting practice to the contrary, and we have no doubt that in the course of time the reasons in favor of this will appeal to the different associations with sufficient force to cause a change to be made. The original argument in favor of the present ruling, which is a reversal of early practice, is that taxes are not within the control of the manager, and that his administration, therefore, should not be held responsible for a non-flexible item of this kind. The real truth of the matter is, however, that taxes are affected as much as any other item in operating expenses by the wisdom or unwisdom of the manager in his dealings

with the public. If he is popular, fair minded and meets the public half way in any propositions for the public good, his company is not nearly so likely to be "struck" by cruel and unusual tax burdens. If, on the contrary, he is too generous, too yielding, too ready to establish dangerous precedents, a load may be fastened upon the company which it can never shake off. Taking either point of view, it can be held as an absolute certainty that management has an influence on taxation as important as that on "wages of conductors and motormen," or any other pure "operating expense," where all that a manager can do is to increase or diminish an average volume of expenditure, which cannot be abolished in its entirety. If, therefore, the test of managerial ability is to be expressed in the percentage of operating expenses to gross receipts, taxes should be logically included, as the Street Railway Accountants' Association decided. The most important thing, however, is uniformity, and, as before stated, we believe that the Street Railway Accountants' Association should accept for the present the practice of the Interstate Commerce Association and other railroad accounting practice.

Should Strikes be Permitted

"If I should allow my men to strike, I should not be worthy of the position which I hold."

These pregnant words uttered by President Vreeland of the Metropolitan Street Railway Company contain a truth well worthy of interpretation, and a secret of successful management.

The employees of a modern electric railway—particularly those in the transportation department—are not unreasoning or unreasonable beings, eager to give ear to the counsel of demagogues or the ravings of the disaffected. On the contrary, they are usually intelligent, frequently ambitious, and always appreciative of the genuine efforts of their employers to improve their condition. It would probably be impossible to-day to induce the employees of the Metropolitan Street Railway Company of New York, for example, to leave its service in a body, because they see in President Vreeland and his department heads chiefs who are sincere and honest in their friendship for the men whom they employ, who are fair and just at all times in dealing with them, and who are ready to aid their employees in the lower ranks of the service to rise to the higher in every practicable way, recognizing merit and ambition wherever it occurs. As Mr. Vreeland frequently says to his men: "There is just as much reason for any one of you to hope that he may become president of this company as there was for me to expect a position of high responsibility twenty years ago, when I was a flagman on the Long Island Railroad." The secret of the hold which a manager can thus obtain upon his men is found in his treatment of them as reasonable fellow citizens, recognizing that each is doing a work as dignified in its way as is that of the department chief or the company's president.

When, therefore, a strike of any magnitude occurs upon a street railway system, it is not safe to assume that the fault is wholly with the men, however unreasonable their demands may seem at first sight to be. There is rarely heavy smoke without some fire, and it is more than probable that men who claim to have grievances are not wholly without the elements of them, particularly as no body of men can afford to ask public sympathy on too flimsy pretexts. If, now, the manager arbitrarily refuses to discuss such grievances frankly and freely, or even if he lets the disaffection grow to serious proportions without quieting it by prompt investigation and correction of abuses, he runs a grave risk of being found unworthy of the responsibilities placed upon him as a "master of industry." His most important business is to make sure that his men have no excuse for striking—nothing which they can urge as a sufficient reason.

It does not follow by any means, however, that strikes can always be avoided. It is often the case that the incoming of a new manager or superintendent, whose intentions, however good, are wholly unknown, is made the occasion of a strike, or of strike talk, which is really an effort to "find the master." Under such circumstances the mischief may have gone too far for correction and the gage of battle must be accepted. Again, a body of employees may be taken into a larger body through railway consolidations, as in Brooklyn, and before it can become assimilated and get used to the new management, disaffection may creep in and be fomented by unworthy labor leaders to the point of rupture. How much blame can attach to a management under these circumstances is not self evident, but depends upon the underlying facts in the case. Other exceptional causes may also lead to strikes without the possibility of putting blame upon the managers. Broadly speaking, however, it is true that the ablest street railway managers of to-day are men who are not troubled by strikes nor the fear of them; they do not hold themselves aloof from their employees, but mingle with them constantly, though without loss of dignity, commanding respect for the position rather than for the man. And they are *honest* in their friendship for the workers in every branch of the service, not simply superficially desirous of being regarded as friendly.

But when a strike is actually declared, it must be fought to a finish, assuming, of course, that the company has deliberately decided beforehand that it can go so far and no further, even if a strike be the consequence. The results of yielding to force what is denied to reason are so utterly disastrous to discipline and success in management, and involve such dangers of renewed attempts to obtain further concessions that almost any loss of money or property is preferable to allowing strikers to succeed in their strike. Arbitration even is usually unwise or impossible in contests of this kind, partly because the results of arbitration, particularly where the matter of wages is to be considered, may mean bankruptcy to a company, and partly because if the decision of arbitrators is unsatisfactory to strikers they rarely, or never, consider themselves bound by it, but often decide to continue the strike until some satisfactory conclusion is reached.

The best guarantee that the public can have that a street railway company will treat its employees with fairness, and that, in the case of strikes actually declared, the burden of proof as to its justification rests upon the strikers and not upon the company, is that "labor troubles" are so costly in their continuance and so disastrous in their effects, that a management will never permit them to be brought about if it is possible to satisfy the demands of the men.

High Speed Electric Railway Between Dusseldorf and Krefeld

The electric railway between Düsseldorf and Krefeld, Germany, which was put in operation a few months ago, is of special interest, as it is the first installation in Europe of a high-speed electric railway. For this reason new methods and apparatus of a kind untried in European countries, had to be installed. An interesting paper on this road was read at a recent meeting of the Verband Deutscher Electrotechniker, in Hamburg, by Gustav Braun, from which the facts given below have been largely taken.

The necessity for a direct connection between the two cities, Düsseldorf and Krefeld, was discussed as early as 1830, and it may be said that the plan has been agitated ever since. Düsseldorf, which is situated on the right bank of the Rhine, and is famous for its enormous industries and as an important railway center and river harbor, has long felt the lack of opportunity to extend more than in one direction on account of the broad river; while Krefeld, situated 6 km. to the left of the Rhine, and the center of the German silk and velvet industry, has felt the necessity of being connected with the neighboring city on account of railroad facilities.

In 1891 the State Minister of Railroads announced that the Government was not willing to grant the subsidy necessary for the building of the bridge across the Rhine required for the projected line, but if the city of Düsseldorf, or a stock company, would build the bridge at its own expense, it could obtain permission for the collection of a reasonable bridge toll. Finally all difficulties were overcome, and the Rheinische Bahngesellchaft was formed in March, 1896, for the purpose of constructing the required bridge at Düsseldorf and an electric railroad from that city to Krefeld.

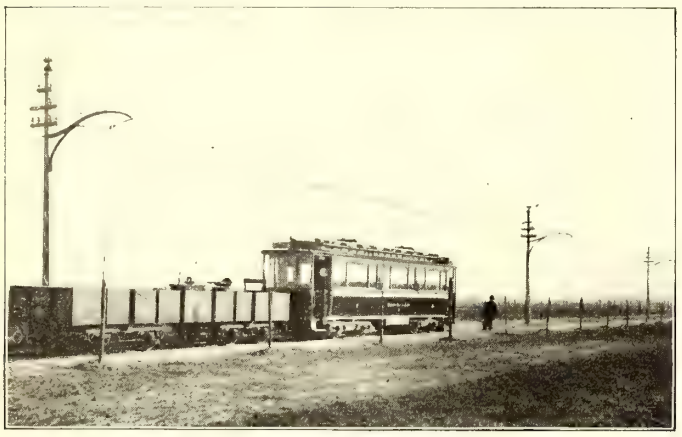
The bridge itself is a handsome structure. The main portion consists of two large spans of 183 meters (600 ft.) each, framed by immense sandstone portals. At either side are a number of smaller spans. For the railroad two tracks have been laid, and two vehicles can pass outside of them at one time with ease. At each side of this roadway are two conveniently wide passenger walks.

As the electric road parallels a steam railway for the greater part of its length it was necessary to adopt a speed of 40 km. (25 miles) per hour on open stretches, and here the highway was avoided as much as possible. For this reason also the road does not pass through the intervening towns, but only touches them on the outskirts.

The route is shown in the map on page 527. The total length of the road from the Haroldstrasse in Düsseldorf to the Rheinstrasse in Krefeld, is 22 km. (13.6 miles). The length of the open stretch between the stopping places, Oberkassel and the Krefeld depot, is 16.7 km. (10.4 miles). The steepest grade is that of the bridge approaches, and is

MOTOR CAR AND TWO TRAIL CARS ON S CURVE IN KREFELD

2½ per cent. Between the starting point in the city of Düsseldorf and the stopping place, Oberkassel, which may be considered the end of the Düsseldorf local traffic, double tracks have been laid, while there is but a single track along the open stretch up to Krefeld, excepting at the stopping places, where double tracks serve as turnouts.



In Krefeld only a small portion is provided with two tracks. The entire road bed, however, has been laid out with sufficient width so that two tracks, on a road bed 9.2 m. wide, can be laid at any time without any difficulty.

As it is the intention to eventually run State railway cars over the open stretch between Oberkassel and Krefeld for private use as well as the needs of the company, the gage and distance between tracks had to be chosen to conform to the needs of these larger cars, which are considerably greater than that required by street cars. On the stretches intended for the latter the distance between tracks is only 2.75 m. (9 ft.) from center to center.

For the portion between the bridge and Krefeld tie con-

struction with Vignol T-rail sections, 11 A of the Prussian railways, were chosen. The rails have a weight of 27.5 kg. per meter (54 lbs. per yard), which is sufficient for the support of the large railway cars, as the lines are not to be used by the locomotives. The rails are laid in 12 m. (39 ft. 4 ins.) lengths, and in this distance fifteen tie rods are used.

The switches are of the tongue type, with a radius of

TRAIN ON HIGH SPEED SECTION BETWEEN OBER-KASSEL AND HEERDT-LÖRRICK

curvature of 150 m. (492 ft.), which permits the use of the railway cars. For the flange rails in the city streets, Phoenix, type 25 A, with a weight of 42 kg. per meter (84 lbs. per yard) were selected.

The construction of the road was started in the beginning of July, 1897. The ground and stone work for the completion of the roadbed was begun first and pushed so quickly that before winter set in the roadbed on the entire open portion, consisting of several cuts, road and railway crossings at Osterath, were finished, and the greater part of the rails laid. In the fall of the same year the building of the central station was started, and roofed before winter, so that during the winter months the machine and boiler foundations could be built. As soon as the warmer weather in year 1898 commenced, the outside work was resumed, and the several depots, which are very handsome, the car barns and workshops, as well as six dwelling houses for officers and workmen, were erected. In April the tracks were laid, in May the poles were placed in position and soon after the trolley line was strung.

Bids for supplying the electrical equipment for the line were requested by the Rheinische Bahngesellschaft in 1896 of a limited number of well-known electrical firms, the results of which gave the company plenty of material for comparison. Though the proposition of the firm Siemens & Halske was found to be the most acceptable, another competition with definite instructions was opened, and again the Siemens & Halske proposition proved the best. On account of the excellent general and special apparatus which this firm proposed to furnish, as well as the splendid operation of all electric lines executed by it, it received the contract for the electrical equipment of the road, that is the construction of the line and car equipment, while the well-known firm, Elektricitäts-Aktien-Gesellschaft, formerly W. Lahmeyer & Co., received the contract for the furnishing of the electrical machinery in the generating station, which had to conform, however, to the plans of the Siemens & Halske Company.

In view of an expected large demand for power by factories, the power house was located at Oberkassel, near one end of the line. In order, however, profitably to feed the other end at Krefeld, an accumulator plant was installed at Fischeln, and housed in the beautiful depot at that place.

The power house is a large, single-story building, containing the boiler, engine and generator rooms, as well as a repair workshop for cars. In the engine room are two horizontal tandem compound condensing steam engines of 270 normal effective h.p. each, and 330 h.p. effective maximum, at a speed of 90 r.p.m. The engines were built by the Hohenzollern Machine Company of Düsseldorf. Directly coupled to them are two shunt-wound continuous current generators, of 330 amps. capacity at 600 volts. Only one of these units is in use at any one time, the other being held in reserve. Besides the above, for the charging of the batteries, at Fischeln two sets of rotary converters have been installed, one for service and one for reserve, which furnish an additional 45 volts.

For the lighting of the station there is another continuous current rotary converter which runs at a speed of 900 rev. 4 amps. at 600 volts, and delivers current at 110 volts pressure. All the electrical machines were furnished by the Elektricitäts-Aktien-Gesellshaft, formerly W. Lahmeyer & Co., of Frankfort-on-Main. All machines in the engine and dynamo room can be reached by a 12,500 kg. (27,500 lb.) crane. Three arc lights illuminate the room.

In the boiler room are two water-tube boilers of 220 sq. m. (2370 sq. ft.) heating surface each, and a pressure of 10 atm. They were also built by the Hohenzollern company.

A voltage of 600 volts was chosen as being best suited in this instance, so as to reduce the cost of the line to a minimum. A higher pressure was not advisable, as this would exclude any possibility of connecting the road with the electric roads of Düsseldorf and Krefeld in the future.

CURVE CONSTRUCTION IN LUEG-ALLEE IN OBER-KASSEL

The overhead line, carried by iron poles, consists of two hard-drawn copper wires 9 mm. in diameter (No. 00),

which are strung 15 cm. (6 ins.) apart, along the single track portions, but are strung on both sides of the roads along the two-track portions and at the turnouts, and doubly insulated from the ground.

In order to prevent interruption of service in case of a break in the trolley wire, a special power wire, 100 sq. mm. in section (No. 0000) is stretched along the entire route, and is connected to the trolley wire at definite distances so that in case the latter should break the current can be interrupted for a length only corresponding to the distance between two successive poles.

The distance between any two points of support is about 30 m. (96 ft.) on the straight open sections and 35 m. (103 ft.) within the city limits. At curves and turnouts the distance is considerably less. The advantage of supporting the trolley wire when the bow-sliding trolley is used over that required by the wheel trolley is especially evidenced by the sharp curves in Krefeld, particularly in the S curves shown in one of the illustrations. The number of points of support of the trolley at this curve is remarkably small.

All wires are arranged so that they can be tightened if they stretch, and every 300 m. (984 ft.) the poles are made specially strong, so that a break in the trolley wire does not cripple the entire line.

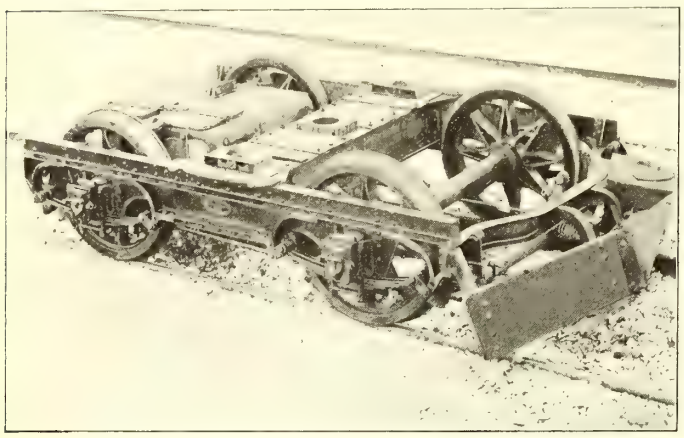
Along the open stretch, from Oberkassel to Dissem, bracket poles are used; at the turnouts and on double track span construction is employed. At the land pillars of the new Rhine bridge the trolley poles also support the arc lamps.

Three feeders lead from the power and accumulator stations to the feeding points at the stopping places. The entire system is therefore divided into six independent sections, which can be separately controlled, and are again subdivided into 1 km. (0.62-mile) lengths. Each one of these is separated from the adjoining one by a line insulator with switch and is protected by a lightning arrester.

The feeders are supported by glass insulators on wooden crossarms, fastened to the upper part of the poles. In order to be able to report the cars along the open stretch the several stations are connected by telephone.

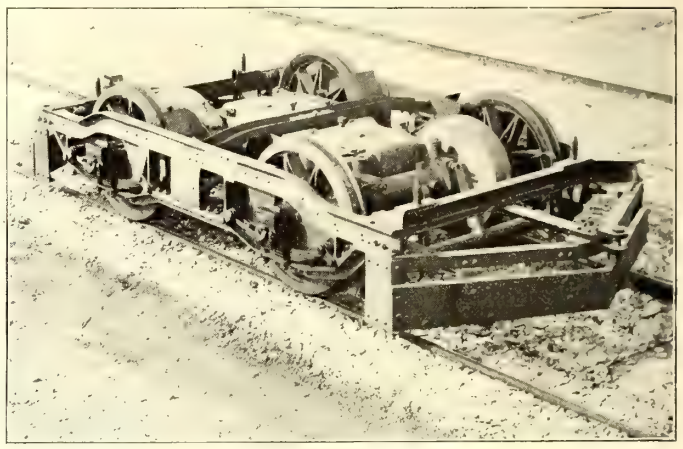
The car equipments, which were also furnished by the Siemens & Halske A. G., and conform to the requirements of this road, possess some departures from usual methods. The motors are mounted direct on the axles without springs. Double trucks are used, and each truck carries on its inner axle a 35-40 h.p. motor. A pair of wheels with armature and magnet frame weighs about 2.9 tons. The field consists of four poles, of which two are consequent. The diameter of the wheels is 800 mm. (31.5 ins.), the wheel base is 1600 mm. (5ft. 2 ins.), and the distance between

CAR FOR LOCAL TRAFFIC



STATION AT FORSTHAUS-ALEER AND TRAIN OF CARS

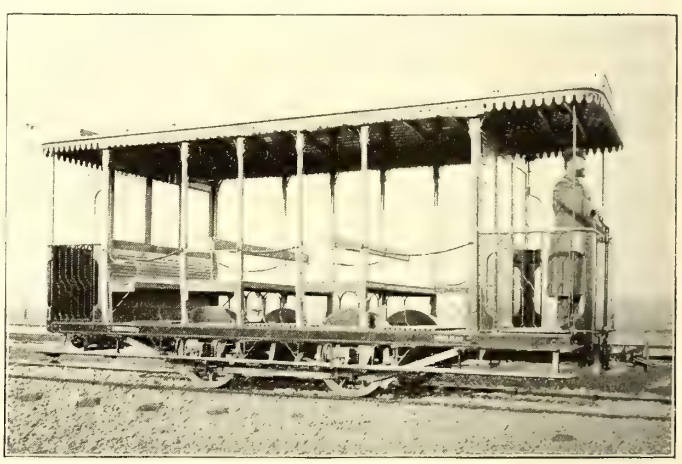
axles 5.9 m. (19 ft. 4 ins.). The over-all length between buffers is 12.4 m. (43 ft.).



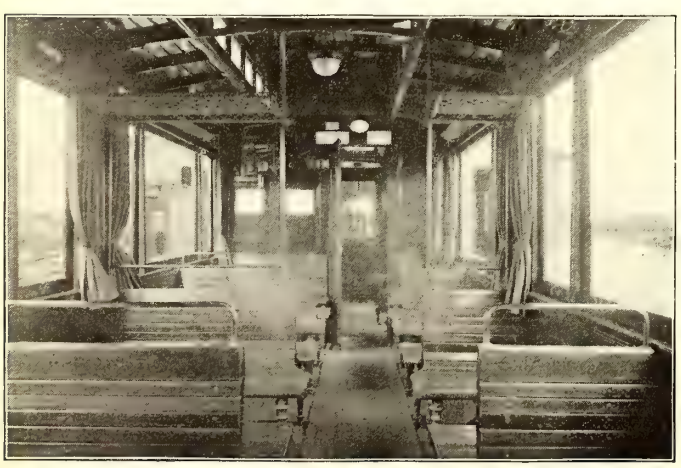
The passenger cars have a seating capacity of thirty-four, and standing room for sixteen, and are divided into II. class (12 seats) and III. class (22 seats), while the trailers in the III. class have cross seats, and those in the II. class have parlor car arrangement. The platforms are provided with glass storm doors; the illumination consists of eighteen 16 c.p. incandescent lamps. There are two lamps in the headlight, of which only one burns, while the other one is held in reserve in case something should happen to the first. The cars are heated with briquettes, by means of a stove under the car frame, to which pipes are attached, running along under the seats. The interior and exterior finish of the cars is extremely elegant compared with other German roads, and care has been taken to make them as comfortable as possible.

The cars can be braked in three different ways, i.e., usually by an air or hand brake, and in case of necessity by an electrical short-circuit brake. The air brake is of the Standard Air Brake Company's type. Its compression pump is coupled direct to a small electric motor, which is wound for 600 volts and uses 3-4 amps. in order to compress the air to 3-6 atmospheres. The two-cylinder, single-acting compressor of 76 mm. (3 in.) piston diameter, and a stroke of 51 mm. (2 ins.) delivers 140 to 200 liters (5 to 7 cu. ft.) of free air per minute, at an average speed of 600 r.p.m. The weight of a four-axle motor car is 18,750 kg. (41,250 lbs.).

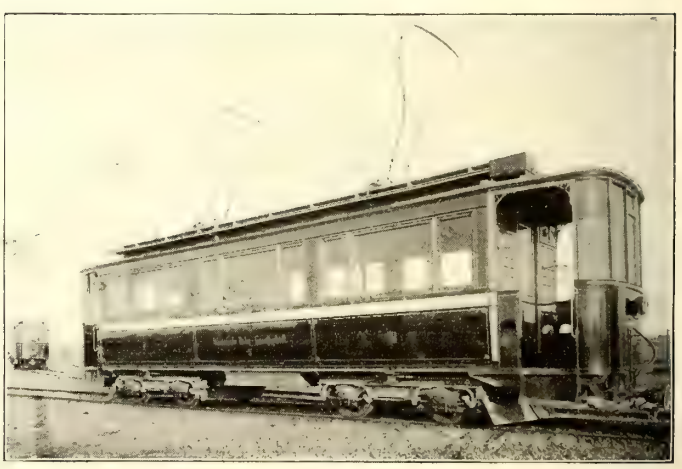
To insure the certainty of the current collection the



DOUBLE TRUCK FOR 8-WHEEL CARS



TRUCK FOR 4-WHEEL CARS



DOUBLE TRUCK CLOSED FREIGHT CAR

SINGLE TRUCK TRAIL CAR

INTERIOR OF OPEN TRAIL CAR

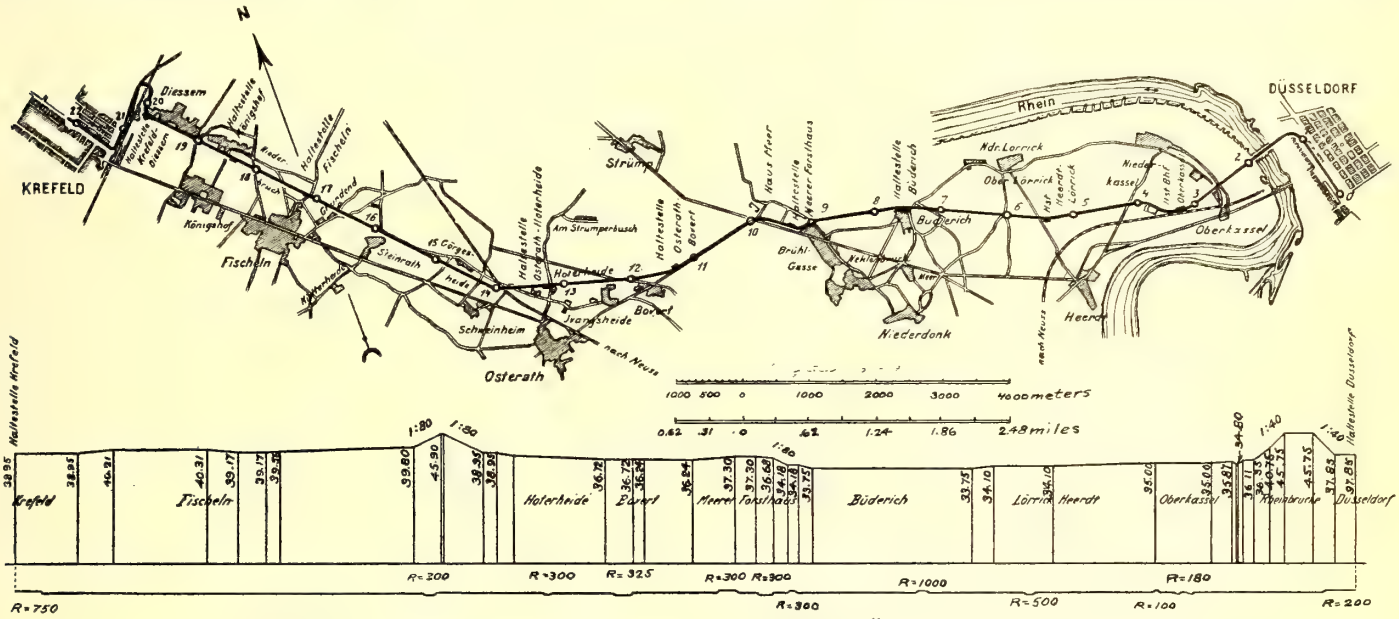
DOUBLE TRUCK MOTOR CAR

motor cars are supplied with two trolley poles of the well-known Siemens & Halske sliding contact type. This has proved satisfactory with the high speed of 60 km. per hour.

The passenger trailers, open and closed freight cars are also supplied with air and hand brakes. The four-axle passenger trailers weigh, empty, 12,100 kg. (26,620 lbs.). For the local service in Düsseldorf and Krefeld two-axle open and closed small cars are used. These closed two-axle passenger cars have a seating capacity of sixteen, and standing room for fourteen, and are elegantly furnished. The open trailers have a seating capacity of twenty-four, and standing room for twelve. Each axle of the motor car is driven by a 20 h.p. electric motor. The current is collected by only one sliding trolley. The local cars are equipped with a hand brake, but here also the electrical brake can be used. The freight cars also have four axles, a wheel base of 1.4 m. (4 ft. 7 ins.), distance between axles 5.2 m. (17 ft.), weigh, empty, 7750 kg. (17,050 lbs.), and can carry a load of 6300 kg. (13,860 lbs.). Trial trips were made at the close of 1898, and speeds of 60 km. (37.2 miles) per hour were obtained, showing that the electrical equipment was suited for even this speed, far in excess of the prescribed speed of 40 km. per hour.

At an early date the building of a 1.2 km. extension of the Düsseldorf portion of the road will be begun, .8 km. of which will be of the underground conduit system of Budapest.

Electric Transportation Systems at the Paris Exposition



Arrangements are being made for the extensive introduction of transportation systems at the forthcoming exposition in Paris in order to accommodate the large number of strangers which, it is expected, will attend. Without counting the Metropolitan road, the Orleans Railroad Company and the Compagnie des Chemins de Fer de l'Ouest will extend their tracks to the entrance of the exposition. Both of these lines will be operated by powerful electric locomotives, so that while the city of Paris will not be able to show any extensive application of electricity to tramway service, visitors will be able to see electric transportation on a large scale, with the employment of heavy electric locomotives.

The plans adopted by the Orleans Railroad Company for the use of 45-ton electric locomotives, with a capacity of 700 h.p., have already been described in the STREET RAILWAY JOURNAL. These locomotives, mounted on four axles, each carrying one 25-h.p. motor, are able to draw a train of 250 tons at a speed of 50 km. per hour. The power station will have a capacity of 2000 kw., and will distribute current on the three-phase system at 5500 volts, with two substations, at which this current will be transformed to 550 volts for traction and 450 volts for lighting the trains.

The Compagnie de l'Ouest has already commenced the construction of a power station, from which it will generate current for, (1) electric traction on its Invalides-Exposition-Versailles line; (2) for the compression of air for its compressed air locomotives; (3) for pumping purposes in its Invalides station; (4) for the electric lighting of its Invalides station; (5) for the electric lighting of its Champs de Mars station; (6) for the operation of elevators.

This power station will contain a number of groups of 1200-h.p. engines, operating 800-kw. three-phase alternators, running at 5500 volts, at which the power will be distributed. There will be three substations at 2.4 km., 6.7 km., and 3.4 km. distance.

The company will also install a number of electric locomotives capable of drawing trains of 120 tons at a speed of 50 km. per hour on a maximum grade of 1 per cent.

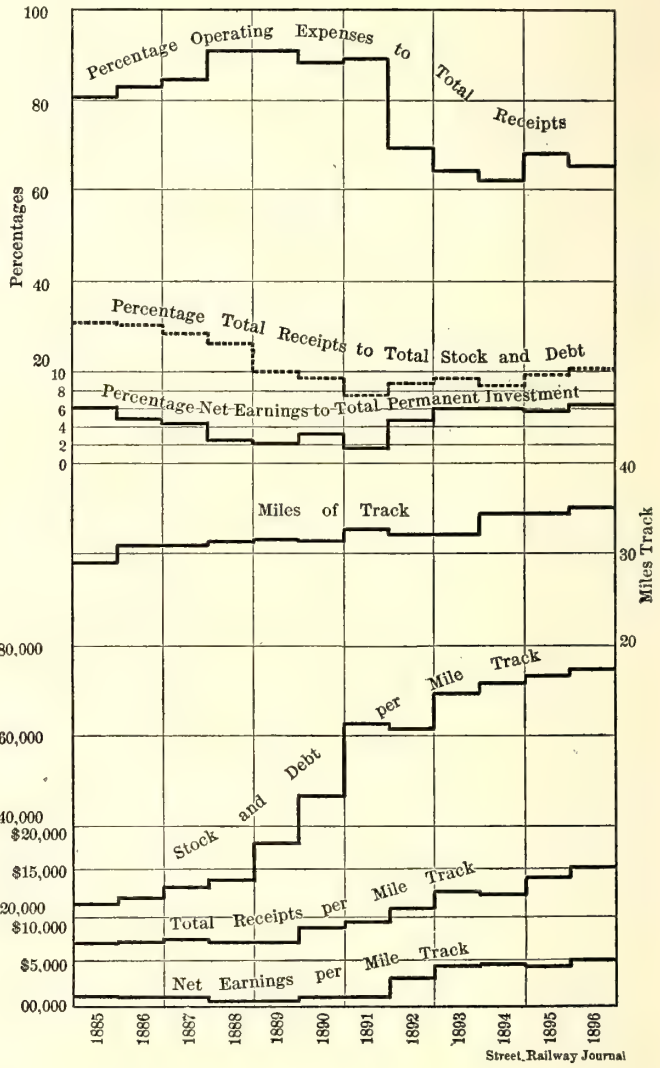
MAP AND PROFILE OF HIGH SPEED RAILWAY BETWEEN DÜSSELDORF AND KREFELD

The road was opened to the public on Dec. 15, 1898, and the service was under the control of the Siemens & Halske A. G., by contract for three months, and it was found that all requirements were met.

For passenger service a through train leaves each terminal station every half hour; for local service between Düsseldorf and Oberkassel the small two-axle cars are used, which have a headway of from 6 to 8 minutes, while the small cars for the local service of Krefeld have a headway of 10 minutes.

The freight and farm service is regular, and the trains have but a small headway. The results of service are as follows:

	January	February	March	April
Kilometers traveled by				
4 axle motor cars	43577.8	38242.9	43864.2	44354.0
" trailers	7298.0	9223.6	10253 0	13141.1
" freight cars	.....	4144.3	4843.3	5202.7
2 axle motor cars	15992.1	14994.1	12869.1	12777.7
" trailers	.....	.....	36.8	453.4
Number of long distance passengers carried	50,763	44,673	45,726	53,576
Number of local passengers carried	43,036	25,643	27,886	30,974



Financial and Operating Reports in Diagrammatic Form for Use of General Managers

During the past two or three years the Street Railway Journal has several times called attention to the value to the street railway manager of diagrams, or "curves," in interpreting the financial results and details of operation of his system. In no other way can five and ten year reports be so well examined and compared. The usual system of comparing "this year" with "last year" by figures is oftentimes unsatisfactory, in that one or both of the two years may be exceptional in certain respects, and it is often, if not always, desirable to have before one on the same sheet the results of several years' operation.

In Figs. 1 and 2* may be seen one form in which the general results from the operation of a street railway for many years can be compared. A diagram in this same form can be made for months, as well as years, so that nineteen diagrams would reflect comparative monthly, quarterly, semi-annual and annual reports covering any desired period—ten, fifteen, or twenty years.

Mr. H. C. Mackay, auditor of the Milwaukee Electric Railway & Light Company, about a year ago presented to General Manager John I. Beggs a pocketbook, in which appeared in diagrammatic form, but on a system somewhat different from that just illustrated, practically all the details of operation, information concerning which would be desired. Illustrations of two or three of the typical pages of this book are given herewith. Each year is traced through the different months by a line of a given color of ink. On completing the year another line commences with January, and is traced through the following year in another color. Five colors, red, black, purple, green and blue are provided for in the general scheme, and the result is, perhaps, more distinct than appears in the accompanying illustrations, where black lines only are used. Every detail of gross receipts and operating expenses, in both railway and lamp departments, is represented by these diagrams in Mr. Beggs' pocketbook, and from the index in front the desired page can be quickly found.

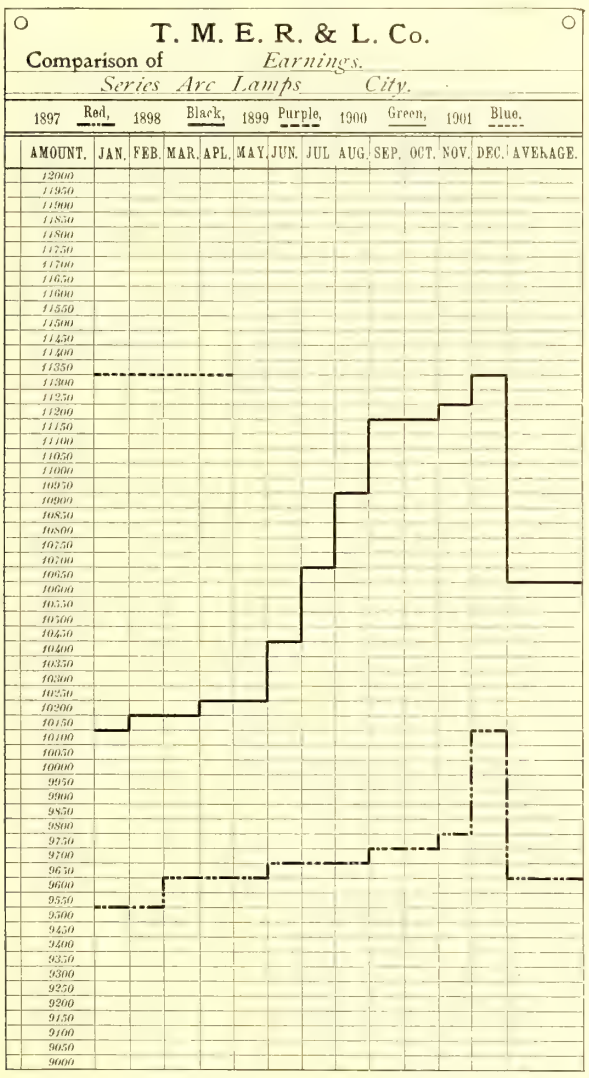
FIGS. 1 AND 2.—MILWAUKEE NOTE BOOK

The general manager of the Maple Leaf line, a large steam railroad of the West, employs a clerk whose sole business it is to translate into diagrams of this form all the figures submitted by the auditing department. In this way Mr. Stickney can rapidly go over the reports of each month, seeing at a glance whether or not pay rolls are being increased or diminished, and to what extent, and where leakages occur, and can get a much better comparative bird's eye view of the entire system in its operating and financial phases than could possibly be obtained in any other way except by the expenditure of far greater time.

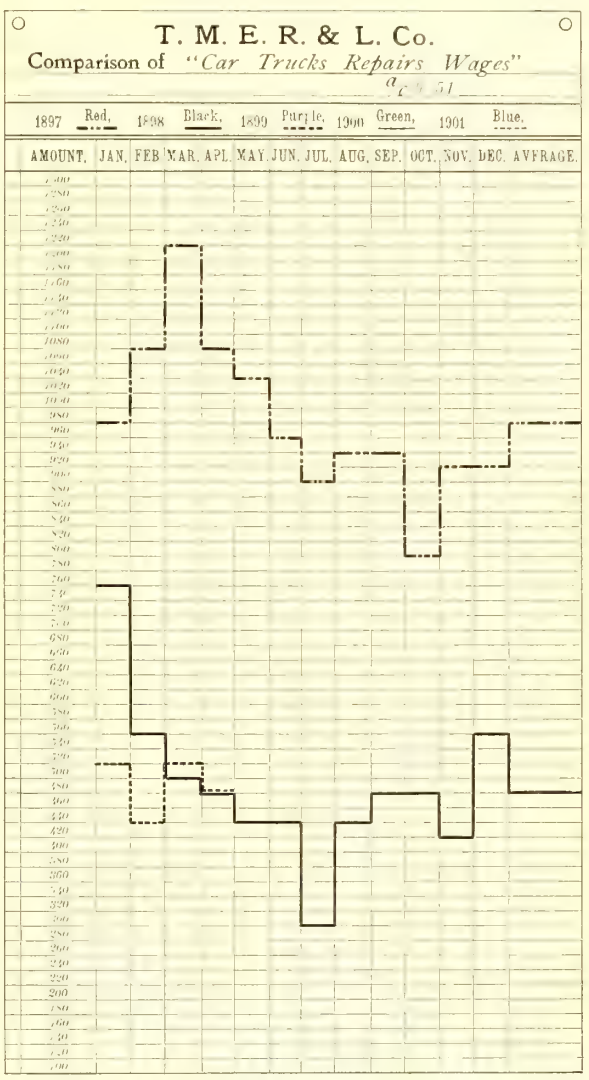
*From Street Railway Journal, July, 1897, pp. 410-11.

Electric Railways at Florence, Italy

One of the first of the modern electric railways in Europe was built in Florence, in 1891, and connected that city with Fiesole, a mountain suburb of the city. During the last year, however, the principal tramway company of the city, la Société des Florentins, has completed the equipment of its lines, comprising about 60 km. of track,



and the famous city of Savanarola, Dante and Galileo now possesses an electric railway complete in modern equipment. The installation was made by the French Thomson-Houston Company, and was put in operation Dec. 5, 1898.

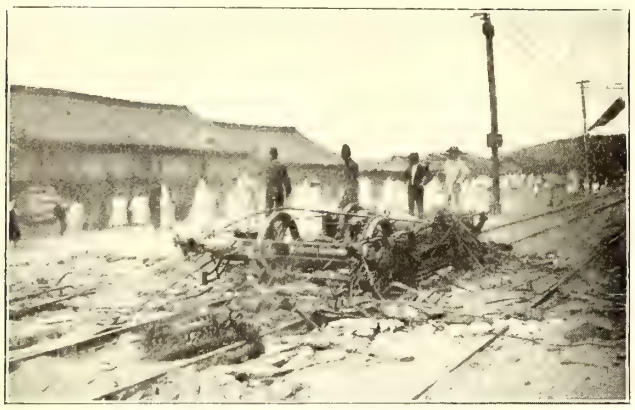


The track construction within the city is made up of the standard Broca rails, weighing 34 kg. per m., and mounted on metal ties weighing 18.75 kg. each, and spaced seven to every ten meters. In the suburbs the Vignole rail is used, weighing 24 kg. per m., laid on oak ties. These rails have a length of 9 meters and each rests on ten ties. The rails are bonded with the Chicago rail bond, 9 mm. in diameter, and are cross connected every 50 meters. The return feeders are made up of old rails weighing 30 kg. per m., connected electrically and buried a distance of 700 mm. in the ground. The outgoing feeders are also carried underground in the center of the city, and are of 250 mm². and 500 mm². section. The suburban feeders are entirely overhead and are composed of bare copper wires of 250 mm². and 125 mm². section.

The overhead system is standard, with a trolley wire 8.25 mm. diameter and is divided into sections of about 50 meters in length, each equipped with a lightning arrester.

The power station is a handsome building, the front of which is finished in the characteristic Italian style with alternating horizontal stripes of dark and light material, and is located about the center of the system. The boiler room contains four Weinlig boilers, each with a heating surface of 155 m². and capable of furnishing 2500 to 3000 kg. of dry steam per hour under a pressure of 9 atmospheres. Green economizers are used, and the chimney is 55 meters in height. The engine room contains three Escher Wyss & Company's tandem, compound condensing engines, two of 700 i.h.p. each and the third of 350 h.p., all running at 120 r.p.m. The air pumps are operated directly from the engine shaft, but the condenser pumps are driven by a 25-h.p. electric motor. A traveling crane of 15 tons capacity completes the mechanical equipment of the engine room.

The generators are of the Thomson-Houston M. P. type. Two are of 425 kw. capacity, and one of 225 kw. capacity. The switchboard is made up of eight panels, of which three are for the generators, two for the feeders, one a totalizer panel, one for the distribution of electric power and one a lighting panel for station and car house use.



FIGS. 3 AND 4.—PAGES FROM MILWAUKEE HAND BOOK

There are seventy-five cars, of which sixty are closed cars, each equipped with two G. E. 800 motors; ten are open cars with the same equipment and five are closed cars equipped with two G. E. 57 motors. The latter cars are intended to act as locomotives in driving ordinary freight cars within the city, where steam locomotives are not permitted. The cars carry thirty-eight passengers each, and are equipped with electric brakes and are mounted on Brill trucks. The company also possesses a number of trail cars which are used on days of special traffic, but are not employed under ordinary operating conditions. These cars are also equipped with electric brakes.

Electric Railroading in Corea

Some of the difficulties of operating electric railroads in oriental countries are almost as great as those experienced in this country, and occasionally a mob will take offense at the management of the railroad and destroy nearly as much property in the same length of time as a more civilized mob provided with improved instruments of destruction can accomplish in the same length of time in this part of the globe.

RUINS OF CAR IN COREA

An incident of this kind occurred on May 26 at Seoul, Corea, where an electric railway has been in operation for a few months. It was the first road of its kind in the country, and at the start the natives took kindly to it, the opening celebration continuing practically for a week. Unfortunately for the railway company, however, soon after the opening of the line a drought occurred, which threatened the failure of the rice crop. As the most likely cause, the natives imagined that rain was cut off by the electric wires, and to them the most obvious way to obtain the needed showers was to remove the objectionable cause. This they proceeded to do by tearing down the trolley wires and burning the cars. The result of a few hours of this pastime is shown in the accompanying engraving, where the only thing left of the cars was the J. G. Brill trucks on which they were mounted, and which do not seem to have been injured by the conflagration above them. It is interesting to note that order was very quickly restored after this example of the mob's violence, as the method adopted by the government was a simple one, and consisted in cutting off the heads of some of the rioters.

CLEANING AWAY THE DEBRIS

The simple minds of the natives soon comprehended that droughts and trolley cars are less serious calamities than the loss of one's head, and are likely to leave the cars alone in the future.

According to the press dispatches of the riot the disturbance was largely quelled by two officers of the company, H. R. Bostwick, formerly of San Francisco, manager of the Seoul Electric Railway Company, and H. Raymond Krumm of Columbus, Ohio, chief of the Imperial Engineering Department, who, alone and unarmed, by their coolness and nerve dispersed a howling mob of from 3000 to 4000 Orientials and saved their own lives, the power house and electric plant.

New Road in Massachusetts

Westminster and Gardner, Mass., are two towns respectively 7 and 12 miles west of Fitchburg, Mass., on the line of the Fitchburg Railroad. The village of Westminster is about a mile and a half distant from the railroad station of that name, and between it and Fitchburg no adequate accommodation for local traffic can be obtained through the steam road. The Gardner, Westminster & Fitchburg Street Railway is an electric line, of which all but three miles have been completed, connecting the three places named. Frederick S. Coolidge, of Fitchburg, is president, and the general management of the road is to be in the hands of M. A. Coolidge, who has the contract for construction, and will do all buying for the work.

A power house and car barn are now being erected at Westminster. H. G. Howard, of Ashburnham, has the contract for the former, which is of brick, 82 ft. x 85 ft. The car barn is being built by M. C. Ryan, of Gardner, and is of wood, with brick underpinning. It will be heated by steam from the power station.

The boilers are three in number, of the horizontal tubular type, 72 ins. in diameter by 21 ft. 6 ins. long, built by D. M. Dillon, of Fitchburg. They are to rest on ordinary brick settings with rough stone foundations and are to have firebrick linings throughout. The engines are two Slater cross compounds, 14 ins. x 28 ins. x 36 ins., of 300 h.p. each. They will be erected on brick foundations over a concrete bed 2 ft. deep, the outside dimensions of the foundations being 25 ft. 4 ins. x 20 ft. 11 ins. The stack is of brick, 10 ft. 8 ins. square outside, with a circular core 5 ft. in diameter and 85 ft. high. The piping contract, including the heaters, pumps, etc., has been placed with the Walworth Construction & Supply Company, of Boston. Warren pumps and condensers, Cochrane separators, Wheeler heaters, Crane valves, Metropolitan injectors and Johns' asbestos fire felt covering will be used throughout. The generators are two 225 kw. General Electric 550-volt machines. The car equipments, also furnished by the General Electric Company, include motors for eight double truck cars. Hodges & Harrington, of Boston, are the engineers for the power plant.

The individuals controlling the road form also a majority interest in the Gardner Street Railway, a road covering some 5 miles of streets in the town of Gardner. This road is at present supplied with power by the Gardner Electric Light Company, but will be operated from the Westminster plant when the latter is completed.

I realize that it is a hard matter for the Government to make a flat rate to cover all roads and the local condition pertaining to each road; but as they have attempted to do this, I claim that they should have made the rate flattering enough to the electric railroads to make them at least interested in the subject, and that three cents per mile for pouch service and sixteen cents per mile for 16-ft. cars, which are fast becoming obsolete and replaced by cars from one-third to twice as large, is not enough. From paper at the Boston Convention, 1898.

The Recent Street Railway Strikes

The Brooklyn strike of July was due to dissatisfaction among the men of the Nassau Electric Railway system, which has recently been taken into the great combination which now controls nearly all the surface and elevated railways of Brooklyn. The Nassau men are said to be made up largely of former strikers who were "locked out" in the last great Brooklyn strike, and who remained out of work until the Nassau system was built by the Johnsons, by whom they were largely re-engaged. Rightly or wrongly, these Nassau men seem to have felt that their past record was being brought against them by the management of the Brooklyn Rapid Transit system, and that sooner or later practically all would be discharged upon one pretext or another. It was also claimed by them that the provisions of the ten-hour law were being evaded and that the men, particularly in the Nassau system, were obliged to run their cars at high speeds under serious nervous strain for more than the legal limit of a day. All other grievances than these two were merely perfunctory or non-existent.

There appears to be little doubt that strike feeling was secretly fostered by Wall Street speculators for the fall, and at a critical moment Albert L. Johnson, formerly president of the Nassau system, came out in open championship of the cause of his old employees, and as a contributor to their funds. Almost immediately after this the strike was declared.

There was never from the first the slightest hope of success. The disaffection was not general, but highly localized, and in spite of the most urgent effort on the part of the strikers, but few of the employees of the Rapid Transit system, outside of the Nassau lines, could be induced to "go out." The strike was short lived, and ended in a lock-out of most of the Nassau men and a few of the remainder. There was some violence, including one serious case where dynamite was used to blow up a portion of the elevated structure, but the prompt and stern determination of the police to preserve order at all costs was largely effective in preventing serious riots or bloodshed.

The strike on the Metropolitan Street Railway system was a roaring farce. The absurd Parsons, Grand Master Workman of the Knights of Labor, pretended at first to represent a powerful organization among the Metropolitan employees, although nearly 90 per cent of the latter had signed a statement which they sent to President Vreeland to the effect that they were entirely satisfied with their treatment, and had appointed no representatives to present grievances. Later on, certain over-enthusiastic followers of Parsons, who were chiefly ex-employees of the Metropolitan Company, demanded that he declare a strike, and although he used his best efforts to prevent this, fearing, no doubt, that the weakness of his alleged organization would thereby become known, he was carried away and practically forced to declare the strike. As a result hardly one hundred men out of the 3500 Metropolitan employees responded to his call. The cars ran almost as usual throughout the city, and the great body of employees remained loyal to the management which has done so much to improve their condition during the past six or eight years. Statement after statement was issued by Parsons to the effect that the tie-up was complete, and the remainder of the men would go out immediately, but the employees themselves laughed him to scorn and went about their business. There was practically no violence on any line except the Second Avenue, where, in fact, the disaffection was chiefly localized, this having been one of the last properties to be brought into the Metropolitan system.

The Cleveland strike in its revived form belongs to a wholly different and far more dangerous class than the New York strike. As Mayor Farley of Cleveland says, "Our people seem to have gone crazy." The strikers have actually come out with a public statement justifying violence as necessary—a very rare thing in strike annals, where the labor leaders generally disclaim all attempts at violence, and frequently allege that it is practiced by the friends of the railway company in order that the men may lose sympathy in their struggle. Never before have high explosives been so freely used as in the Cleveland strike to date. Cars have been blown up, bombs have been thrown into car houses, shots have been fired at cars, passengers and non-union motormen, and the latter have been maltreated at every opportunity. To quell the insurrection, for it is little less than that, the local troops have all been ordered out, and the State troops called for, and Mayor Farley states that no effort will be spared to stop the reign of terror which now exists in Cleveland. It is much to be feared that a large part of the trouble has been due to lack of firmness of the city government in dealing with the strikers at the beginning of the difficulty, but the authorities now seem fully aroused to the occasion, and the result cannot be in question.

New Railway in Ohio

The new line being built at Galion, Ohio, by the Ohio Central Traction Company is nearly completed, and the company will commence operations soon. The company owns 12 miles of track, laid with 60-lb. T rails, and about eight cars. Four of these cars will be 36-ft. double-truck combination cars, and four ten-bench open cars. The cars will be mounted on the Brill maximum traction and No. 21 trucks, and the cars will be built by the American Car Company. The power station will contain two 250-h.p. Slater engines, two 150-kw. General Electric generators, and two 250 water tube boilers built by the Turner Engineering Company, of Bucyrus, Ohio. Located on the route of the road will be a park, known as Secaium Park. It comprises 58 acres, and is being fitted up with a summer theater, which will seat from 800 to 1000 persons, also with a large pavilion, seats, tables, etc. The president of the company is I. A. Kelsey, of West Haven, Conn., and the general manager, W. E. Haycox.

Chartered Car Rates in Rochester

The Rochester Railway Company, of Rochester, N. Y., publishes the following as the rates for chartered cars during the coming season:

CITY LINES

One motor car to any point	$4.00
One motor car and return	6.00
One motor car and trailer to any point	5.00
One motor car and trailer and return	9.00

CHARLOTTE AND WINDSOR BEACH

One motor car one way	$6.00
One motor car one way and return	10.00
One motor car one way with trailer	9.00
One motor car one way with trailer and return	14.00

CHARTERED CARS (BY THE HOUR)

First hour	$4.00
Each hour after	2.00

PRIVATE CAR

First hour	$5.00
Each hour after	2.00

One motor car and trailer will carry 100 passengers comfortably

LEGAL NOTES AND COMMENTS*

Edited by J. Aspinwall Hodge, Jr., of the New York Bar

The Constitutionality of the Ford Amendment to the New York Tax Law

In the June number of the Journal we commented upon the taxation of franchises, and especially upon the tax proposed by what was known as the Ford Franchise bill, which has since become an act of the New York Legislature, after having been amended in two important particulars.

The constitutionality of that act, owing chiefly, if not wholly, to the amendments which were made to it at the instance of the Governor in the extra session of the Legislature, is being seriously questioned and upon two grounds.

First, it is contended that the act is unconstitutional in that it provides for the appointment by the Governor of officers who shall make local assessments for the purpose of taxation; while the constitution provides, in section 2, of article 10, that all State, town and village officers whose election or appointment is not otherwise provided for by the constitution, shall be elected by the electors of such city, town or village or appointed by such authorities thereof as the Legislature shall designate for that purpose.

The supporters of this contention cite the case of the People vs. Raymond, 37 N. Y., 428. Chapter 410 of the Laws of 1867, provided for the appointment, by the Governor, of an officer to be known as the Commissioner of Taxes and Assessment of the City and County of New York, and the constitutionality of the act was attacked in that case.

In answer to the argument made by the counsel of the opponents of the act that additional powers and duties were conferred upon the office created by the act, and that the office was a new one, and so was not within the prohibition of the constitution, the court observed:

"If offices can thus be made new, the section of the constitution above quoted may readily be made a nullity. I am far from conceding that it would be competent for the Legislature to take from the city all control over the assessment of the property of the city for purposes of taxation, and vest this power in the central authority, by conferring powers upon the officers or boards, upon which they conferred it over other subjects, and imposing duties upon them entirely foreign to those of making the assessment."

But it is to be noted that the powers and duties of the commissioner under that act were limited to the territory of the city and county of New York.

We are not able to subscribe to the proposition that this case establishes the proposition for which those who cite it contend, especially in view of other decisions of the Court of Appeals, beginning with the case of the People vs. Draper, 15 N. Y., 532, the doctrine of which was reaffirmed in the People vs. Shepard, 36 N. Y., 285.

The Draper case involved the constitutionality of the act creating the Metropolitan Police District. There the Court of Appeals held that an act was constitutional which created the office of Police Commissioners (who were admittedly local officers when appointed for a single city) to act in a territory to be known as the Metropolitan District, including the city of New York and some contiguous territory. And this, notwithstanding that it was admitted that had they been appointed for a single city, the prohibition of the constitution would apply and notwithstanding that it was contended with reason that the act created a new political division of the State.

It will be noticed that the Ford bill appoints officers who would be local were they appointed for any particular city, but gives to them powers and duties over the entire State. The act, therefore, is not as open to constitutional objections as the act passed upon in the Draper case, for no new political division of the State is created by the Legislature fiat, and the State officers who are appointed have duties in every city alike.

It is quite true that the Draper case was very severely criticised in the Court of Appeals in the case of the People vs. Albertson, 55 N. Y., pp. 50, 64, but the criticism there made by Judge Allen, writing for the Court, is rather directed to the creation of the Metropolitan District than to the proposition which is involved in the appointment of a general State officer to perform duties throughout the State, and distinguishes between an office created for a particular locality and one which covers a larger legitimate political division.

The principle of the Draper case that the officer who performs duties beyond, as well as within, the limits of a particular locality is not a local officer of that locality, whatever his duties may be in it, has never been overruled by the Court of Appeals.

The second, and it seems to us more serious objection, to the constitutionality of the act, is that the tax levied is unequal.

By the amendment to the bill, it is provided that if it shall appear that the person or corporation owning a franchise has paid during the preceding year to the city, town or village any sum of money on account of the franchise, all such amounts, except such as is paid for paving or repaving the streets, shall be deducted from the tax levied and the remainder shall be the tax that is payable by the holder of the franchise.

We have in a preceding article referred to the inequality which distinguishes between a payment on account of paving and payments made for other purposes. But the objection on the ground of inequality is broader and goes deeper.

It would readily be admitted that a system of taxation is unconstitutional, because unequal if it provides that a real estate owner who could show that he paid a larger sum for his property, which he had purchased from the State, than his next door neighbor, should have a deduction made from the tax levied upon him. Yet this is what the amended Ford act does.

An individual or a corporation (for the act applies to both) who owns a franchise is to be granted a deduction if he is, by some previous agreement, paying a part or the whole of the purchase price in instalments. As between a corporation which has paid a lump sum for a franchise and one which has bargained for an annual payment, however computed, the discrimination is seemingly unjust and the tax unequal.

The only answer to this serious objection is that the State might have remitted the annual payment; in other words, forgiven its debtor, and then levied a tax on all alike. Thus in two acts, neither of which would have been unconstitutional, the Legislature would have accomplished the same result as has been attempted in the Ford act. The supporters of the constitutionality of the act are entitled to any comfort they may derive from that consideration.

H.

CHARTERS, ORDINANCES, FRANCHISES, ETC.

CONNECTICUT.—Franchise—Location—Terminus—Description.

A street railroad charter described the location and terminus of the road as "over and through Main street in the town of S. to

* Communications relating to this department may be addressed to the Editors, Johnston Building, 30 Broad Street, New York.

a convenient point in said town, where connections can be made with the 'S. & P.' Electric Railroad," and authorized it to connect with any other street railroad. Held, that the terminus was sufficiently described, and the right to build the road was not affected by the fact that the "S. & P." road was abandoned, and connection could not be made with it.—(Central Ry. & Elec. Co. vs. N. Y., N. H. & H. R. R. Co., 43 Atl. Rep., 490.)

NEW YORK.—Nuisance—Implied Powers—Injunction—Appeal.

1. Where the trial court does not fully state the facts found, but decides that defendant's conduct amounts to a nuisance, the Court of Appeals, after an affirmance by the Appellate Division, must assume the existence of the nuisance.

2. Where a statute authorizes a company to construct and operate a railroad, the implied authority to operate a turntable in connection therewith does not justify its operation, so as to constitute a private nuisance.

3. Where a continuing trespass is shown, which must necessarily result in substantial damages to plaintiff's property, which are in no way offset by benefits, a permanent injunction may be issued, although the amount of the damages is not fixed.—(Garvey vs. Long Island R. R. Co., 54 N. E. Rep., 58.)

LIABILITY FOR NEGLIGENCE.

ALABAMA.—Injuries to Passenger Alighting—Argument of Counsel—Instructions—Negligence—Discharge of Passenger—Sudden Starting—Contributory Negligence.

1. In an action for death of a passenger, caused by a sudden jerk of a street car while he was attempting to alight therefrom, the evidence tended to show that, through negligence of the conductor, the car was carried beyond the passenger's destination. The conductor testified that the passenger was drunk, used profane language, and made faces at some women on the car. There was evidence to contradict these statements. Held, that a statement of plaintiff's counsel, in argument, that, not satisfied with taking the passenger's life, the conductor attempted to rob him of his good name, was not improper.

2. In an action for death of a passenger, claimed to have been caused by a sudden jerk of a street car while he was alighting, a passenger testified for the company that, to the best of his recollection, the car stopped at the crossing. All of the company's testimony was not introduced to show that the car so stopped. Held, that a charge that some of the testimony offered by the company tended to show that the car stopped at the crossing was not erroneous.

3. In an action for death of a passenger, claimed to have been caused by a sudden jerk of the car while he was alighting therefrom, a witness testified that the car slowed up almost to a standstill, it being hard to tell whether it was going or standing still. The court charged that some witness testified that the car so nearly stopped that its motion was almost imperceptible, but subsequently withdrew the statement, saying merely that some of the testimony tended to show that the car slowed up. Held, not error.

4. Where a street car, having failed to stop at a crossing in compliance with a passenger's request, slows up beyond such crossing to such an extent as to imply an invitation to him to alight, it is the duty of the operatives not to cause the car to jerk suddenly so as to endanger his safety.

5. Where a street car slows up to allow a passenger to alight, and he is injured by a sudden jerk thereof, his attempting to alight before the car actually stops cannot be held contributory negligence, as matter of law, but it is for the jury to determine, though the passenger carried a small bundle under one arm (which, however, was not shown to have incumbered him), whether he was negligent or not.

6. In an action for injuries to a passenger, some witnesses testified that, when the street car had slowed up nearly to a standstill, the passenger attempted to alight, and by a sudden jerk of the car was thrown down. Other witnesses testified that the passenger was thrown from the platform after the car had started, and while it was going six or eight miles an hour. It was admitted that the passenger was negligently riding on the steps or platform in violation of the rules. Held, that a charge that such negligence alone would not defeat a recovery, unless it proximately contributed to the injury, was proper.

7. In an action for injuries to a passenger, claimed to have been caused by a sudden jerk of the car, throwing him off, a charge that, if the injury resulted from the passenger's riding on the platform, he could not recover, was properly refused, as it did not hypothesize such riding as the proximate cause.

8. Ordinarily it is not, as a matter of law, contributory negligence for a passenger, when the street car is slowing up to allow him to alight, to go upon the platform or steps before the car has actually stopped.—(Birmingham Ry. & Elec. Co. vs. James, 25 So. Rep., 847.)

CONNECTICUT.—Crossing Track—Negligence—Evidence—Default—Appeal—Review.

1. In a negligence case, in which the question of legal liability is purely that of prudent conduct under circumstances peculiar to the case, and no violation of law by the trial court is apparent from the record, its conclusion as to negligence or legal liability, including the measure of duty and the extent of its performance, is final.

2. Deceased passed a street car standing at its termius ready to start in the direction in which he was traveling with a wagon. After traveling alongside of the track for some time he turned to cross the track, and was struck by the car and killed. He did not stop before turning across the track, and it did not appear whether he looked back or listened before attempting to cross. He was slightly deaf. When he started to cross the car was at least 70 ft. from him, and he had time, at the speed at which he was driving, to have crossed the track ahead of the car had it been going at its ordinary and proper rate of speed. Held, in an action to recover for deceased's death, that he was not guilty of contributory negligence as a matter of law.

3. On the hearing in damages after a default in an action against a street railway company to recover for death of a person run over by its cars, it appeared that deceased was driving alongside of the track, and turned to drive across the track, when he was struck by a car from behind and killed. The car was coasting down a heavy grade at a speed greater than its ordinary, proper rate, and after seeing deceased on the track not less than 70 ft. ahead of him, the motorman was unable to stop the car until after it had gone 200 ft. further, though it could be stopped within 70 ft. when going at its usual rate of speed. In trying to stop the car the motorman failed to sand the track, which was slippery in places. Held, that a finding that the street railway company had not shown its freedom from negligence was warranted, as after the default the burden of proof was on it.—(Lawler vs. Hartford St. Ry. Co., 43 Atl. Rep., 545.)

ILLINOIS.—Injury to Persons Near Track—Questions for Jury—Instructions—Motion in Arrest of Judgment.

1. Plaintiff was on a crossing near a sidewalk, beside a policeman, waiting to cross a street crowded with vehicles, when defendant's cars came around a curve at a speed of about six miles an hour, and the gripman, not seeing or not heeding the policeman's signal to stop, ran against a vehicle, throwing it against plaintiff, causing her injury. Held, that whether plaintiff was exercising ordinary care for her own safety, and whether defendant was negligent, were questions for the jury.

2. The refusal of an instruction limiting the damages alleged to have been sustained by plaintiff to a just compensation for the injury is not erroneous, where the court had instructed that no exemplary damages were allowable.

3. A motion in arrest of judgment, because of a defect in the record, in that the declaration was not filed ten days before the second term of the court at which the suit was begun, is properly overruled, where the declaration was filed before the date on which defendant was served with summons.—(Chicago City Ry. Co. vs. Roach, 54 N. E. Rep., 212.)

ILLINOIS.—Personal Injuries—Evidence—Instructions.

1. Where, in an action for personal injuries caused by plaintiff's wagon being struck by defendant's car, there was evidence that after the wagon was struck it was carried 70 to 80 ft. before the car could be stopped, and there was conflicting evidence as to the rate of speed at which the car was moving, the question whether the car was moving at a negligent rate of speed was properly left to the jury.

2. Where there is no evidence that defendant was negligent in any manner other than that charged in the declaration, and the jury were charged that the evidence must show that defendant was negligent as charged in the declaration, a charge to find for plaintiff if they found defendant negligent is not error, although it does not limit the negligence to that alleged in the declaration.—(West Chicago St. Ry. Co. vs. Musa, 54 N. E. Rep., 168.)

INDIANA.—Receivers of United States Courts—Action for Death of Husband—Damages—Instructions—Instantaneous Death—Survival of Cause of Action.

1. Under 25 Stat., 436, providing that every receiver of any property, appointed by any United States court, may be sued in respect to any act or transaction of his in carrying on the business connected with such property, without previous leave of the court in which he was appointed, but such suit shall be subject to the general equity jurisdiction of the court in which he was appointed so far as necessary to the ends of justice, an action can be maintained in the State courts against a receiver operating a railroad for negligence, without first obtaining leave from the United States Court appointing him.

2. Five thousand dollars is not an excessive verdict in favor of a widow for the wrongful death of her husband where he was in good health; fifty years of age; was at at the time of his death earning $1,150 per annum as United States postal clerk, which position he had held for seventeen years; left a wife and two children dependent upon him, nineteen and fourteen years old, and his expectancy of life was about twenty-one years.

3. In an action for wrongful death, it is not necessary to show that deceased would have been able to continue to earn what he was receiving at the time of his death, or what part of his earnings he expended for the benefit of his family, or what part of his time he spent with his family, or what part he took in raising and educating his sons, in order to entitle his widow to more than nominal damages.

4. In an action by a wife for the wrongful death of her husband, an instruction that she is entitled to recover for the pecuniary loss sustained by her is not erroneous, as being vague, in defining the damages to which she was entitled, in the absence of a request for more explicit instructions.

5. In an action under the statute, which provides that whenever the death of a person shall be caused by the wrongful act of another, and it is such as would, if death had not ensued, entitled the party injured to maintain an action and recover damages therefor, then the person who would have been liable if death had not ensued shall be liable to an action by the personal representative of deceased for the exclusive benefit of the widow and the next of kin, an instruction that plaintiff cannot recover if her intestate's death was instantaneous is erroneous, as the statute does not contemplate the survival of a cause of action which would otherwise abate with death, but creates a cause of action.—(Malott vs. Shimer, 54 N. E. Rep., 101.)

INDIANA.—Actions for Death of Child—Who May Sue.

Under Horner's Rev. St., 1897, Sec. 266, providing that a father (or, in case of his death, the mother) may sue for damages for injury or death of a child, a woman who is neither the mother of a child nor has legally adopted it cannot maintain an action for damages for its death, although she has raised it from infancy, and maintained and supported it as her child.—(Citizens' St. Ry. Co. vs. Cooper, 53 N. E. Rep., 1092.)

KANSAS.—Degree of Care—Injury to Passenger—Acts of Intermeddler—Negligence of Employee—Objections to Evidence.

1. A street railway company is bound to the highest possible caution and prudence in letting off its passengers at its stopping places, and its employees must not merely wait a reasonable time to enable the passengers to alight, without looking to see whether such has been done, but they must see and know that the passengers are safely off before starting the car in motion again.

2. When a street railway car is negligently started in motion before a passenger endeavoring to leave it has safely alighted from it, and while it is so in motion the passenger is seized with an attack of dizziness, which prevents him from holding on, and, in consequence, he falls off and is injured, the company is liable.

3. A street railway company is not responsible for injuries resulting from the act of an intermeddler in the running of its cars, which its employees could not foresee and guard against; but when such act of intermeddling consists in giving the signal to start the car in motion, and the conductor in charge, without seeing and knowing that a passenger has safely alighted before the car started, does not stop it as soon as can be, but allows it to continue in motion in obedience to the unauthorized signal, he will be held to have ratified and adopted the act of the intermeddler, and the company will be liable for the consequent injury as caused by an act of its employee's negligence.

4. If, by custom among street railway employees, known and assented to by the company, those who are on duty are in the habit of calling for and receiving assistance from those who are not at the time on duty, and an employee off duty, thus called upon, undertakes to render the assistance asked, he will be regarded as in the employ of the company for such service; and, if he negligently abandons the work before completing it, whereby injuries to a passenger occur, the company will be liable.

5. If, however, such custom does not exist, or, existing, is not known and assented to by the company, but an employee on duty deputes the one off duty to assist him, and he undertakes to do so, but negligently fails to fully perform it, whereby injury to a passenger occurs, the company is likewise liable, because of the negligent abandonment of duty by the employee directly chargeable with its performance.

6. When additional bodily injuries and damages resulting therefrom were not alleged in the plaintiff's petition, but evidence of them was received upon the trial without objection by the defendant, and upon which evidence the defendant cross-examined the witnesses giving it, an objection to it cannot be made for the first time by a request to instruct the jury to disregard it in making up their verdict.—(Leavenworth Elec. Ry. Co. vs. Cusick, 57 Pac. Rep., 519.)

MICHIGAN.—Crossing Street Car Tracks—Duty to Look—Contributory Negligence.

A woman, twenty-six years old, who has crossed street car tracks at the place where she is injured for about a year, and is familiar with the running of cars thereon, will be guilty of contributory negligence when she stands about six feet from the track to permit a car to pass her, and then passes behind the car and in front of a car on the other track, going in the opposite direction, by which she is injured, and there is a space of 5 ft. between the tracks, and no physical obstacle to prevent her seeing the approaching car if she looks after the first car passes.—(McCarthy vs. Detroit Citizens' St. Ry. Co., 79 N. W. Rep., 631.)

MINNESOTA.—Injury to Passenger—Evidence—New Trial.

1. On the evidence, held, that the St. Paul City Railway Company and the Minneapolis Street Railway Company were jointly operating the Interurban Line, partly owned by each, and connecting the two cities, and each one is liable for the acts and omissions of the other in operating the same.

2. Held, the uncorroborated evidence of the plaintiff on the vital and essential point in the case is so inherently unreasonable and improbable that the trial court abused its discretion in failing to grant a new trial.—(Messenger vs. St. Paul City Ry. Co., 79 N. W. Rep., 583.)

MISSOURI.—Harmless Error—Speed of Car—Ringing Bell—Negligence of Parents—Instructions.

1. Failure of a street car company to equip its car with a fender, which would have prevented the injury complained of, is not, in the absence of an ordinance or statute requiring it, negligence.

2. Where, on cross-examination, a witness for defendant says that he testified in a certain way before the coroner, and his testimony on the trial is substantially the same, it is harmless error to allow counsel for defendant to read his testimony before the coroner (Rev. St. 1889, Sec. 2303), providing that the Supreme or Appellate Court shall not revise a judgment unless it believes that the alleged error materially affected the merits.

3. In an action to recover for injuries alleged to have been caused by the negligence of defendant's motorman and conductor, it is competent for the motorman (who has been shown to be experienced), after testifying to what was done, to testify that there was nothing else that he could have done, under the circumstances, to prevent the injury, as such testimony does not preclude the jury from finding from the other testimony that he could have done something which he failed to do.

4. In an action to recover for personal injuries, plaintiff alleged that defendant was negligent in running its cars at a greater rate of speed than was permitted by an ordinance. The evidence disproved this allegation. Held, that the court properly took the question of negligence on account of the speed of the car from the jury, as plaintiff was not entitled to rely on common-law negligence as to its speed.

5. A complaint alleged that defendant was guilty of negligence in failing to ring the bell on its gripcar as it approached the crossing where the injury occurred. Plaintiffs witnesses testified that they did not hear the bell, but admitted they were not paying attention, while defendant's witnesses testified that the bell was rung twice, which was the usual signal at a crossing. Held, that an instruction, at defendant's request (plaintiff making none), that, if the jury found from the evidence that the gripman rang the bell as the train approached the crossing, it must find for defendant on that issue, is not erroneous.

6. It is not error to refuse to give an instruction, though it states the law correctly, where there is no evidence in the case on which to predicate it.

7. An instruction that defendant is liable, even though the parents of the child killed were negligent in permitting it to be on the street unattended, if the person operating defendant's car which killed it was negligent, and his negligence was the immediate cause of the injury, and by the exercise of ordinary care and precaution the injury might have been avoided, is properly refused because it excludes the principle that defendant would be liable if, after the discovery of the danger in which the child was, the exercise of ordinary care would have averted the injury, and it failed to exercise such care, or if it failed to discover the danger through its own recklessness, when by the exercise of ordinary care it could have discovered the danger and averted it, and because it makes defendant liable, if negligent, though the negligence of plaintiff contributed to the injury.—(Hogan et al. vs. Citizens' Ry. Co., 51 S. W. Rep., 473.)

MISSOURI.—Injuries to Passengers—Negligence—Riding on Footboard—Contributory Negligence—Instructions—Trial—Witnesses—Contradiction.

1. In an action against a street railway company for the death of a passenger, caused by collision between the car on which he was riding and a broken-down wagon on the track, there was evidence that the gripman was engaged in conversation with a passenger, and was not looking at the track ahead of him. Passengers on the train testified that they saw the wagon on the track when within 50 to 125 ft. from it, and the driver of the wagon and another testified that the driver had gone up the track about 60 ft. to warn the approaching car, but that the gripman paid no attention to him; the evidence being conflicting whether the car could have been stopped within 40 ft. or in not less than 75 ft. Held, that the question of the gripman's negligence was for the jury.

2. A passenger on a cable car notified the gripman of his intention to get off at a crossing, and preparatory to doing so stepped on a footboard running alongside the car on which persons getting off the car were obliged to step. The motorman failed to stop at the crossing, and stated he would let the passenger off at the next crossing, and thereupon the passenger remained standing on the footboard, though there were empty seats in the car, and, before reaching the next street he was killed by the car colliding with a wagon on the track. Held, that the passenger was not guilty of contributory negligence in remaining on the footboard while the car was going to the next crossing, the position not having been voluntarily assumed by him.

3. Nor was he guilty of contributory negligence in that he saw the obstruction which caused the injury on the track ahead of the car in time to have stepped back into his seat, and failed to do so, as he had a right to assume that he would be carried safely, and that the gripman would see the obstruction in time to prevent a collision.

4. A passenger confronted with sudden danger while on a car is not guilty of contributory negligence merely because he fails to exercise what might have seemed to others the best judgment in trying to avoid the danger.

5. In an action against a street railway company for the death of a passenger from injuries received while riding on a running board used to step on in getting on and off the car, an instruction that if the passenger voluntarily left his seat in the car to ride on the running board, and that he would not have been injured had he not been standing thereon, and if the position on the running board was an unsafe one for passengers, no recovery can be had, is properly refused, since it prohibits a recovery notwithstanding the carrier's failure to exercise the greatest care to carry him safely, though he had voluntarily assumed an unsafe position.

6. In an action for the death of a passenger from injuries received while riding on a car, an instruction that if the passenger voluntarily left his seat, and took up the position in which he was injured, and that he would not have been injured had he remained in his seat, no recovery can be had unless the person in charge of the car saw him in his position of danger in time to have prevented the injury, is properly refused, as it assumes that the position which the passenger took was dangerous as a matter of law, and that no recovery could be had, though the injury was caused by the negligent management of the train.

7. A witness cannot be contradicted by proof that on a prior occasion he expressed an opinion at variance with the facts testified to by him.

8. In an action for the death of a street car passenger from injuries caused by the car in which he was riding colliding with an obstruction on the track while the passenger was riding on the footboard of the car preparatory to getting off, the charge being negligence, in that the collision could have been avoided with ordinary care, an instruction that the carrier is liable if the injury was the result of even slight negligence in the management of the train, is not erroneous as enlarging the issues.

9. A street railway company is bound to exercise towards its passengers the utmost care and diligence of a very cautious person, and an instruction that it will be liable if its servants are guilty of even slight negligence is proper.

10. In a negligence case the court need not, in its charge, define the word "negligence."

11. In an action for the death of a street car passenger, caused by the car in which he was riding colliding with a wagon, an instruction using the term, "a broken-down wagon and obstruction which was at said time upon and in close proximity to the tracks," is not erroneous as assuming that there was a broken-down wagon on the track, where the evidence shows that part of the wagon extended over one of the rails for a distance of one foot.

12. Nor is such an instruction erroneous where the carrier has requested an instruction, assuming that there was an obstruction on the track, thereby conceding the fact.

13. In an action for the death of a passenger caused by the car in which he was riding colliding with an obstruction on the track, an instruction that the carrier is liable if its servants in charge of the car saw the obstruction in time to stop the car and avoid the danger, or could, by the exercise of the care required of them, have seen it in time to stop the car, followed by an instruction as to the degree of care required of a carrier, is not erroneous as requiring the carrier's servant to stop the car when he saw the obstruction, though too late to avoid the injury.—(Sweeney vs. Kansas City Cable Ry. Co., 51 S. W. Rep., 682.)

NEW YORK.—Appeal—Review—Questions Considered.

1. In an action by a husband for the loss of his wife's services through injuries received by her, the husband cannot for the first time on appeal raise the question that the joint negligence of the wife and defendant cannot defeat his rights.

Crossing Accidents—Contributory Negligence.

2. The question whether a person run over by a street car at a crossing was guilty of contributory negligence is for the jury, where it appears that, before stepping into the road, she looked in both directions for approaching cars, and then walked fast towards the other side of the street, and stepped on the track on which she was struck, without again looking.—(Hickman vs. Nassau Elec. R. R. Co., 58 N. Y. Suppl., 858.)

NEW YORK.—Injury to Passengers—Defects in Roadbed—Notice.

1. A passenger was injured in alighting from a street car by the giving way of the roadbed, which was elevated, the street having been cut down to a lower level. The proof did not show by whose agency the street was lowered, but similar accidents had happened to passengers alighting from defendant's cars in that vicinity. Held, that, even if defendant was not responsible for the lowering of the street, it was bound, knowing the defective condition of its roadbed, to inform passengers about to alight thereon that they could not safely do so.

Same—Exercise of Due Care.

2. While a street railway company may not be obliged to furnish a passenger a safe place to alight from its cars, where they are stopped not at a regular stopping place at his instance, yet, if it has provided any portion of its roadbed as a place for passengers to alight, it must exercise reasonable care to keep that particular place safe for the purpose.—(Flack vs. Nassau Elec. R. Co., 58 N. Y. Suppl., 839.)

NEW YORK.—Master and Servant—Personal Injury—Negligence of Co-Employee.

1. Two bobtail horse cars, each in charge of a driver, met on the same track. At the request of one of the drivers, a boy about twelve years of age got on the rear platform of his car, which was a safe place, to drive the horse back to a switch, while the driver took charge of the brake at the other end. It was necessary for the driver to get some one to assist him, as there were no other employees of the company in the vicinity. Other boys boarded the car, and the driver pretended he was coming through it to catch them, whereupon they scrambled off, and pushing the boy who was driving off the the platform, he fell under the car and was injured. Held, that, assuming that the boy was an emergency employee, and that his injury was due to the negligence of the driver, he and the driver were co-employees, and the railway company was not liable.

Trespasser on Street Car—Personal Injury—Company's Liability.

2. A boy boarded a bobtail car, at the request of the driver, to drive the horse attached to the hind platform back to a switch, while the driver attended to the brake at the other end. Other boys boarded the car, and, on the driver pretending he was coming through to catch them, they scrambled off, and, pushing the boy driving off the platform, he fell under the car and was injured. Held, that, assuming that he was a trespasser, the company was not liable, since the driver could not have foreseen that the injury would result from his act, and hence it was not the proximate cause thereof.

Passenger for Hire.

3. A boy about twelve years old, at the request of the driver in charge of a bobtail street car, which met on a single track, got on the rear platform, to which the horse was hitched, and drove back to a switch, while the driver attended to the brake. Held, that he was not a passenger for hire, and that the railway company was not liable for an injury caused by the negligence of the driver.—(Marks vs. Rochester Ry. Co., 58 N. Y. Suppl., 210.)

NEW YORK.—Injuries to Passengers—Negligence—Evidence.

In an action for injuries received in alighting from a street car, plaintiff testified that the car suddenly started as she was attempting to take hold of a brass rail on the car to aid her in getting off, thereby throwing her to the ground. The conductor and two disinterested witnesses testified that, while the car was still in motion, plaintiff, though told by the conductor to wait until it stopped, got off, and was thrown to the ground. Held, that a finding that plaintiff's injuries were caused by starting the car too

soon, was against the weight of the evidence.—(Ormond vs. Metropolitan St. Ry. Co., 58 N. Y. Suppl., 335.)

NEW YORK.—Injury to Passenger.

A verdict for plaintiff in an action against a street car company for injuries alleged to have been received by the car starting while she was alighting at a street crossing is not conclusive, but will be set aside, as against the weight of the evidence, where the uncorroborated evidence of plaintiff that the car started while she was alighting was contradicted by the conductor, gripman and two disinterested witnesses, who testified that the accident happened north of the crossing, and that plaintiff alighted from the car before it came to a stop.—(Connor vs. Metropolitan St. Ry. Co., 58 N. Y. Suppl., 340.)

NEW YORK.—Injuries to Passengers—Evidence.

Plaintiff testified that a street car was started after it had stopped, and after he had a foot on a step, and he was thrown into an excavation and injured. A person on the opposite side of the street partially corroborated and partially contradicted plaintiff's testimony. Six other persons who were near the place of the accident, two of whom were disinterested passengers, testified that the car did not stop at all, and that plaintiff fell into the excavation before he touched the car. Held, that a judgment for plaintiff was not sustained.—(Hansen vs. Third Ave. R. Co., 58 N. Y. Suppl., 282.)

NEW YORK.—Railroads—Turnouts—Right to Construct.

1. A city deeded a strip of land in a street to a railroad company and its lessees, successors and assigns, with the right to use it for the purposes of tracks and turnouts in the same manner as on land ceded by it to the city. A successor of such company leased such strip to another, whose charter authorized it to maintain a railroad with necessary appendages. Held, that the lessee company could construct a necessary turnout from its tracks on such strip to a freight yard situated near it.

Same.—Right to Connect—Intersection.

2. Under laws 1890, chap. 565, sec. 4, subd. 5 (laws 1875, chap. 606, sec. 26, subd. 3), authorizing any corporation formed thereunder to join or unite its railroad with any other railroad before constructed at any point on its route, the two roads need not actually intersect in order that a connection be authorized.

Street Railroads—Elevated Railroad—Right to Connect.

3. Laws 1839, chap 218, re-enacted in laws 1890, chap. 565, sec. 78, makes it lawful for any railroad corporation to contract with any other railroad corporation for the use of their respective roads, or any part thereof. Laws 1875, chap. 606, sec. 26, subd. 3 (laws 1890, chap. 565, sec. 4, subd. 5), which contemplated the construction of elevated street railroads, provides that any corporation formed thereunder may join or unite its railroad with any other railroad before constructed at any point on its route, and upon the grounds of such other road; and sec. 26, subd. 5, prohibits any elevated railway company formed under the act from using or occupying any streets except those designated for its route. Laws 1890, chap. 565, sec. 129, prohibits any such company from constructing a street surface railroad. Held, that an elevated railroad company could connect with a surface railroad company, and that they could agree for the use of each other's tracks, the connection being entirely on the latter company's land.

Railroads—Viaduct—Right to Connect.

4. Where a city deeds a railroad company a strip of land in a street for the purpose of railroad tracks and turnouts, to be used and traveled over by cars and locomotives and otherwise, in the same manner as the tracks on land ceded by the company to the city, the company may construct a viaduct on such land to connect with an elevated railroad.

Same.—Connecting with Freight Yards.

5. Such company may also, by another viaduct, connect such viaduct with its freight yards, situated near such land.

New York City—Connection of Railroads—Consent of Assembly.

6. The granting of permits by the Highway Commissioner of New York City to an elevated and a surface railroad to connect their tracks by a viaduct so as to enable each to operate its cars on the tracks of the other, does not create a new franchise, so as to require the consent thereto of the Municipal Assembly, under sections 72-74 of the charter.

Same.—Authority of Highway Commissioners.

7. Under New York charter, secs. 524 and 525, giving the Commissioner of Highways cognizance and control of the laying or relaying of railroad tracks in the streets, and providing that there shall be no disturbance of the street except with his permission, he has authority to permit an elevated railroad to connect with a surface road under an agreement for the use by each of the other's tracks.—(Gallagher vs. Keating et al., 58 N. Y. Suppl., 366; affirmed on appeal, 57 N. Y. Suppl., 632, 1123.)

Further Progress Towards Standardizing Street Railway Reports

The following is a copy of the report made by C. N. Duffy, chairman of the Committee on a Standard System of Street Railway Accounting of the Street Railway Accountants' Association of America, to President Calderwood covering the action taken at a meeting of the representatives of several railway accounting associations, held in New York City, July 11:

St. Louis, July 21, 1899.

John F. Calderwood, Esq., president of the Street Railway Accountants' Association of America, Minneapolis, Minn.:

Dear Sir.—In response to the invitation of Wm. O. Seymour, of the Board of Railroad Commissioners of the State of Connecticut, to attend a meeting at the Manhattan Hotel, New York City, on July 11, 1899, to confer with the committee representing the National Association of State Railroad Commissioners, and a committee representing the Association of American Railway Accounting Officers, for general discussion upon the subject of a classification of construction and operating expenses of street railways, I beg leave to report that Wm. F. Ham and myself attended this meeting, representing the Street Railway Accountants' Association of America.

The following gentlemen were present at the meeting: Wm. O. Seymour, member of Board of Railroad Commissioners of the State of Connecticut, and chairman of committee on classification of construction and operating expenses for street railways; Ashley W. Cole, chairman Board of Railroad Commissioners of State of New York, and a member of Mr. Seymour's committee; H. M. Kochersperger, Comptroller, New York, New Haven & Hartford Railroad Company, and a member of committee representing American Railway Accounting Officers Association; J. D. Greene, Auditor of Disbursements, Pennsylvania Railroad Company, and a member of committee representing American Railway Accounting Officers Association; Wm. F. Ham and C. N. Duffy, representing Street Railway Accountants' Association of America, and H. T. Billings, clerk, Board of Railroad Commissioners, State of Connecticut.

After a morning and afternoon session, in which was discussed the report of our committee made to the Street Railway Accountants' Association of America, at its second annual convention in Boston, the following modifications and changes were uanimously agreed to by all the gentlemen present:

1st. The sub-heading "Car Service" under "Transportation," which includes operating expense accounts numbers 16 to 24, was changed to "Operation of Cars."

2d. Account No. 8, "Maintenance of Miscellaneous Equipment." In the second paragraph the phrase: "Repairs and renewals of all harness should be charged to this account," should be followed by: "The cost of replacing horses lost by death or worn out in service, and the depreciation in the value of horses should be charged to this account."

3d. Account No. 30, "Stable Expenses," which now reads: "Charge to this account the cost of feed, keep and shoeing of horses, replacing horses lost by death or worn out in service, depreciation in value of horses, and all other stable expenses," should be changed to read: "Charge to this account the cost of feed, keep and shoeing of horses, and all other stable expenses." A fourth paragraph should be inserted, to read: "The cost of replacing horses lost by death or worn out in service, and the depreciation in the value of horses, should be charged to account No. 8." This will necessitate a change in the printed report as it appears on page 35.

4th. The number of operating expense accounts is to be thirty-eight, Nos. 1 to 38 inclusive, account No. 39, "Taxes," is to be eliminated from operating expense accounts and classified as a "Deduction from Income."

This will necessitate a number of changes in phraseology, punctuation, etc.

5th. In the monthly and annual reports, under "Deductions from Income," the first item is to be "Taxes."

After the modifications and changes referred to above were unanimously agreed to by all of the gentlemen present, Mr. Seymour announced that at the annual meeting of the National Association of Railroad Commissioners, to be held in Denver, Aug. 11, 1899, his committee would report to the convention, recommending the adoption and use of the standard system of street railway accounting adopted by the Street Railway Accountants' Association of America, with the modifications and changes as agreed upon, which he would have embodied in his report, and that he was confident that his association would unanimously

adopt the report as presented. Mr. Seymour stated that he would have at least 200 copies of the system printed, containing the modifications and changes as agreed upon, together with blank reports printed to conform thereto, and that he would have the street railways of the State of Connecticut make their annual reports for the fiscal year beginning in 1900, on these new forms.

Mr. Kochersperger and Mr. Greene, representing the American Railway Accounting Officers' Association, stated that they would report to their association at its next annual convention, to be held in May, 1900, the result of this conference, and they would recommend the adoption and use of the street railway accounting system, with modifications and changes as agreed upon.

Mr. Ham and myself, on behalf of the committee representing the Street Railway Accountants' Association of America, agreed to all the modifications and changes that were made, and stated to the gentlemen representing the other two associations that we would present a report at the next annual convention of our association, to be held in Chicago in October, 1899, embodying what was agreed upon, and assured the gentlemen that we were confident that our association would sustain us in what we had done.

Through the co-operation of the various associations represented at the New York conference Mr. Ham and myself are satisfied that the standard system will be used by all of the street railway companies of the United States, and that a uniformity of methods and results, which has been so much desired, and for which we have so earnestly labored, will now be attained.

In explanation of the modifications and changes that were agreed to I beg leave to submit the following:

1st. As to changing the title of the sub-heading "Car Service" from "Car Service" to "Operation of Cars," Mr. Kochersperger and Mr. Greene stated that the title "Car Service" would conflict with a technical term used in the operation of steam railroads, and with an account that steam railroads carried on their books, which represents a car mileage account, as I understand it. In addition, it was suggested by the gentlemen that the title of the sub-heading "Operation of Cars" was preferable to "Car Service," and was in uniformity with the title of the first sub-heading under "Transportation," "Operation of Power Plants." Mr. Ham and myself readily agreed to this suggestion, and we both considered not only the objection to the other title well founded, but the name of the new title an improvement over the old.

2d. As to transferring from account No. 30, "Stable Expenses," to account No. 8, "Maintenance of Miscellaneous Equipment," the cost of replacing horses lost by death or worn out in service, and the depreciation in the value of horses, Mr. Kochersperger and Mr. Greene criticised the action of our committee in classifying this item as a "General Expense" account, for the reason that they thought that the cost of maintaining horses was a maintenance charge, and should be classified under the same account that carried the cost of maintaining the wagons and horses. They pointed out that the wagons, harness and horses were one, in the sense that the wagons and harness were useless without the horses, and that, in their opinion, account No. 8 should carry the cost of maintaining wagons, harness and horses, in order to have the classification consistent. In this, Mr. Ham and myself thought that unquestionably they were correct.

3d. As to eliminating account No. 39, "Taxes," from "Operating Expense" account, and classifying same as a "Deduction from Income," in view of the fact that under the Inter-State Commerce Classification of Accounts, the universal standard followed by steam railroads, and the position taken by all of the boards of railroad commissioners throughout the United States that exercise any supervision over the books and accounts of street railways, to consider "Taxes" as a "Deduction from Income," and not as an "Operating Expense Account," and, for the sake of bringing about a uniformity of methods and secure the co-operation of the National Association of State Railroad Commissioners and the Association of American Railway Accounting Officers, all of the gentlemen representing these two associations being firmly fixed in their opinion that "Taxes" should not be a part of the operating expenses of railroads, Mr. Ham and myself agreed to change our classification of operating expense accounts to conform with theirs.

A copy of this report will be sent to each of the gentlemen who attended the meeting at the Manhattan Hotel, New York City, July 11, 1899; to the two members of the committee of the Street Railway Accountants' Association, besides yourself, who were not present at the meeting; to the secretary of our association, and also to the two honorary members of our association, H. H. Windsor, of the "Street Railway Review," Chicago, and E. E. Higgins, of the STREET RAILWAY JOURNAL, New York, as both of these gentlemen are deeply interested in the subject, and will no doubt give our association the benefit of the columns of their papers to further the work of our committee.

I trust that what was accomplished at the meeting and the action taken by Mr. Ham and myself will be endorsed and approved by the other members of our committee, as well as ratified and confirmed by our association at the next annual convention.

Very respectfully,

C. N. DUFFY,

Chairman of Committee on Standard System.

Proposed Solution of Municipal Franchise Problems

The following extract from Allen Ripley Foote's new work upon "Municipal Public Service Industries" is worthy the attention of street railway managers as a proposed equitable solution of the way in which to carry on public service industries with private capital in the interests of the municipality:

Franchises should be granted to municipalities by a general State law, uniform in its provisions for every town and municipality. This law should constitute every incorporated town and city a legal corporation for the purpose of rendering industrial public services, and clothe them with power to own and operate in the name of and for the benefit of the municipality and of its inhabitants, one or all public service industries, when ever such a policy is determined upon by a majority vote of all registered municipal voters.

This law should require:

1. That every public service industry owned by a municipality shall be owned and operated as a monopoly in order to secure for the people all benefits derivable from natural monopolies.

2. That municipalities deciding to transfer a public service industry from private to public ownership shall take possession of all existing property, by whomever owned, then being used for the purpose of rendering such service, under proceedings for the exercise of the right of eminent domain, or by arbitration, if so mutually agreed upon with the owners of said property.

3. Municipal authorities to dedicate public possessions to and to take private property for the special use required for the effective rendering of the service, and to adjust the distribution of special burdens or benefits created thereby, by an assessment of damages or benefits on the private property affected, as for other public improvements.

4. The taxation of all private and public users of the service on the basis of the cost of service used plus such profit, if any, as the Municipal Council may determine; and that no service shall be furnished to a public or private user free of charge, or at a price less than the full and entire costs of ownership and operation.

5. Every municipality to include in all statements of cost made to determine the price to be charged to public and private users for service rendered:

(a) Interest on the entire investment at the rate paid by the municipality on its bonded debt.

(b) The cost of insurance against loss by accidents of all kinds.

(c) The value of municipal taxes relinquished by reason of municipal ownership.

(d) The amount of State taxes paid.

(e) The cost of insurance against the impairment of investments by reasons of depreciation from use and improvements in mechanical arts.

(f) The cost of all material consumed.

(g) The cost of all salaries and wages paid for administration and operation.

(h) The cost of all sundry expenses not otherwise classified and included.

6. An addition to cost, for the purpose of determining selling price, of a sufficient annual provision for a sinking fund to fully pay at their maturity all bonds issued on account of the industry.

7. All municipalities to keep books for each public service industry owned and operated by them, in the form prescribed by the State, and to subject the same to an audit whenever required by the duly authorized officer of the State.

8. The creation of a competent *Board of Municipal Regulation*, which shall have immediate supervision of and be responsible to the Municipal Council for details of administration and operation. Said board shall determine all qustions of engineering, mechanical and operating details, and shall report to the Municipal Council at stated periods all information necessary for its guidance in deciding questions of public policy pertaining to the service.

9. All employees shall be protected in their right to employment by civil service regulations, which shall provide that no employee shall be discharged without cause, set forth in a written statement signed by the officer ordering the discharge, and after a proper opportunity to be heard in his own defence.

10. The Municipal Council shall determine the rates to be charged public and private users for services rendered to them, for periods of five years, and shall provide that all services rendered to any municipal department, or to the municipality in any way, shall be estimated and paid for at a fixed price, out of appropriations for such department, or for the general expense of the municipality.

11. The Municipal Council, on the recommendation of the Board of Municipal Regulation, may lease to a private person, partnership or corporation the municipal franchise and property then used for the purpose of a public service industry owned by the municipality on terms that will secure to the municipality all the benefits of municipal regulation provided for in the act, and the additional advantages of employing private capital, for which interest on the entire investment shall be paid at the same rate per cent as the municipality is at that time paying on its bonded debt, and all responsibility and risks of management to be assumed by the lessee, in consideration of the determination of rates for periods of five years, to be charged by said lessee for services to be rendered to public and private users, on the basis of cost as herein provided, plus a profit calculated at twice the rate per cent of interest then paid by the municipality on its bonded debt, such lease to terminate at the expiration of any period of five years, at the option of the municipality.

12. To reimburse the State for the loss of taxes relinquished by municipal ownership and for the expense of supervision and auditing municipal public service accounts, and for the publication in an annual volume by the State, which is hereby required, in form to facilitate reliable comparisons, of the reports of all municipal public service industries, each municipality shall pay to the State an annual tax of 1 per cent on its gross receipts from the sale of service to public and private users.

These requirements are designed to develop the highest attainable degree of efficiency for municipal governments, the agent to which the people must intrust the administration of their public service industries when they adopt the policy of municipal ownership and operation.

It is only through expert and honest management, the just individual distribution of the burdens of providing the required investment, and of the costs, responsibility and risks of ownership and operation, and by the just distribution of benefits collectively earned, that the people can hope to realize from municipal ownership and operation the full measure of the advantages they seek.

NEWS OF THE MONTH

The Manhattan Railway Company, of New York, has purchased about 120 lots just north of its present terminus at 177th Street and the East Side. It is not known whether this foreshadows the extension of the elevated system to Fordham or the establishment of new storage and repair yards and shops.

Recent newspaper reports to the effect that the General Electric Company was to engage in the automobile business and move a large portion of its Schenectady plant to Lynn are authoritatively denied, and the report that large steel works are to be established at Lynn for the manufacture of castings is pronounced premature.

The organization of the National Tube Company, a consolidation of the wrought iron, steel tube and pipe industry of the United States, was completed on July 12. The required capital was furnished by J. P. Morgan & Company and their friends. Twenty-one companies operating in New York, Pennsylvania, West Virginia and Ohio are included in the combination, and their combined output at present is about 1,100,000 tons of all classes of tubular goods per annum. The capital stock is $80,000,000, of which half is to be 7 per cent preferred stock, and half in common stock. The officers are: President, Edmund C. Converse; chairman of the board, Joshua Rhodes; first vice-president (in charge of manufacturing), F. J. Hearne; second vice-president (in charge of mercantile affairs), Horace Crosby; third vice-president (financial), Francis L. Potts; general manager (manufacturing department), A. S. Matheson; treasurer, Arthur F. Luke; assistant treasurer (at Pittsburgh), William H. Latshaw; general counsel, Sullivan & Cromwell.

The second annual meeting of the Pacific Coast Electric Transmission Association was held at San Francisco, Cal., on June 20 and 21, 1899. Prominent electrical transmission engineers were present from all parts of the Pacific Coast, and a valuable discussion of this subject took place. Papers were read as follows: "Tests and Calculations for a Forty-Mile Aluminum Wire Transmission Line," by F. A. C. Perrine, of Stanford University; "Electric Lighting vs. Gas," by John Martin, president of the Yuba County Power Company; "Regulation of Alternating Current Generators," by C. L. Corey, of the University of California; "Electrically Driven Centrifugal Pumps," by L. A. Hicks, of the Bakersfield Gas & Electric Company, and "Prices for Current Supply," by C. W. Hutton. Officers for the ensuing year were elected as follows: President, Prince A. Poniatowski, of the Standard Electric Company, of California, with headquarters at Stockton, Cal.; vice-president, A. G. Lamson, of Salt Lake City, Utah; secretary, George P. Low, of the Journal of Electricity; treasurer, William Angus.

The New York & Long Island Terminal Railway Company, which has asked for franchises to construct a tunnel railway to be operated by electricity, under the East River, has elected the following officers: President, W. H. Baldwin, Jr.; vice-president, C. M. Pratt; treasurer, A. C. Bedford, secretary, George D. Pratt. All of these gentlemen are connected with the Long Island Railroad.

The new contract between the Twin City Rapid Transit Company, of Minneapolis, and the United States Government for carrying the mails gives the company $1,666.35 per year, which is at the rate of three cents a car mile for the 53,545 miles traveled by the mail carrying cars between Minneapolis and St. Paul, in the course of a year. The company is also to receive $975.02 for carrying mail in Minneapolis. The new agreement is for four years.

At a recent meeting of the Massachusetts Electric Companies the following officers were chosen: President, Amos F. Breed; vice-president, Charles E. Cotting; secretary, Everett W. Burdett; treasurer, J. H. Goodspeed. Executive committee will consist of Gordon Abbott, Charles Francis Adams, 2d; E. N. Foss, Percy Parker and Philip L. Saltonstall. P. F. Sullivan will be general manager.

President Gould, of the Manhattan Railway Company, has authorized the statement that his company has secured a location for its power house at Seventy-fourth and Seventy-fifth Streets and the East River. The plot has a frontage of 204 ft. on the river and 570 ft. on the side streets. It is also announced that the contract for 9000 tons of rail to be used as the third rail conductor, and weighing 100 lbs. per yard, had been given to the Lackawanna Steel Company, the material to be delivered in September. Bids have also been asked for and received from the leading engine and boiler manufacturing companies in the country for the necessary power station equipment. No decision has been reached as to the electrical equipment. W. E. Baker, the electrical engineer of the company, is at work upon the various problems connected with the change of motive power on the system.

What is probably the largest order for steel rails ever given at one time has been placed with the Carnegie Steel Company by the Russian government. The order is for 180,000 tons of steel rails, to be delivered within twenty-six months, and it is said the price is the highest quoted this year, and was not less than $25 per ton at the mill.

As announced first in these columns some time ago, Jesse Spalding has been elected president of the Chicago Union Traction Company. The new general manager will be John M. Roach, for many years vice-president and general manager of the North and West Chicago systems. Louis Owsley, formerly secretary and treasurer of the West Chicago Street Railroad Company, has been elected treasurer of the consolidated properties, and J. Charles Moore, formerly secretary and treasurer of the North Chicago system, has been elected secretary. F. E. Smith, until now with the Lynn & Boston Railroad system, has, as previously announced, become general auditor of the consolidated properties.

The Electric Vehicle Company has placed an order for 4200 electric automobiles with the Columbia & Electric Vehicle Company. The contract amounts to over $8,000,000.

A regular service from the New York end of the Brooklyn Bridge to Coney Island has been instituted on the Fifth Avenue branch of the Brooklyn Union Elevated Railroad Company. From the bridge to Twenty-fifth Street the trains are run by the Sprague multiple unit third-rail system. Each train consists of a motor car and two trailers. The trail cars are equipped with motors and an overhead trolley pole. On reaching Twenty-fifth Street the trains are broken up, and the trail cars proceed to Coney Island as independent motors, taking their current from an overhead wire.

The property of the King's County Elevated Railway Company, of Brooklyn, was sold on July 7, as originally advertised, although on July 6 it was announced the sale would be postponed for twenty days, owing to a restraining order secured by the New York Bank Note Company. At the last moment, however, an agreement with the Bank Note Company was effected, and the sale proceeded. The property was purchased by the reorganization committee. Immediately after the transaction a new company was incorporated at Albany under the name of the King's County Elevated Railroad Company, to take over the road. The capital stock of the new company is $8,800,0000, of which $2,800,000 is 5 per cent preferred and $6,000,000 common stock. The incorporators are E. Mora Davison, Wilton C. Percy, Charles H. Werner, George S. Bonner, Walter F. Wood, Adolph Frank and William J. Cahill, of New York city, and John L. Wells and Benedict Hamburger, of Brooklyn. It is stated that two-thirds of the stock of the King's County Elevated Railway Company will be exchanged for securities of the Brooklyn Rapid Transit Company at once. As soon as this is done, the electrical equipment of the road with the third-rail system will be completed as rapidly as possible.

Owing apparently to worn or defective feeder cables on the section of the Union Loop, of Chicago, the positive side of the circuit became grounded a few days ago, and traffic was stopped for more than an hour, while brilliant displays of electric fireworks were made on the structure. It took some time to locate the defective cable. Meanwhile, the South Side trains were switched back at their old terminus at Congress Street, and the Lake Street and Metropolitan roads were gradually put into service about half an hour apart. No serious damage was done.

The Rochester Railway Company has built a new mail car, modeled after somewhat different lines from the mail cars formerly in operation on that road. The old style cars had the doors at the ends, but in the new type the doors have been placed in the center of each aisle, this being done to prevent the motorman or conductor from gaining admission to the sorting department.

In a recent interview Charles T. Yerkes, of Chicago, stated that his plan is not to desert Chicago, but to give his active attention to the development of suburban and elevated transportation business, the former through the Chicago Consolidated Street Railway Company, and the latter through the interests which he still holds in the Lake Street and Northwestern Elevated Railways.

The Corporation Counsel of Illinois announces that he has discovered that the statutes of Illinois contain a franchise tax law as sweeping in many particulars as the provisions of the new Ford law of New York State.

At the weekly meeting of the Manhattan Railway Company, held on July 11, it was decided to place a contract with the E. P. Allis Company, of Milwaukee, for eight 8000-h.p. engines capable in the aggregate of developing 100,000 h.p. It is stated that the price paid is above $1,000,000. The contract will be drawn and executed as soon as possible.

The Montreal Street Railway Company was recently fined $2 and costs for permitting two of its cars to become overcrowded in violation of a city ordinance.

The Coney Island & Brooklyn Railroad Company has renewed the existing contract and agreement between itself and its employees for another year, or until July 1, 1900. The employees express themselves as satisfied with the treatment they have received and the best of feeling evidently exists.

The Ashtabula Rapid Transit Company has reduced the working hours per day of all its men from sixteen to eleven hours. The employees will receive the same pay as before.

It is probable that within a short time a stable trolley car will be put in operation in Detroit, for the purpose of moving valuable race horses from the railroad stations to the training stables at the race track in the suburbs of the city. The inside of the car will be padded, and each end will be divided into three stalls, making accommodations for six horses. The doors will be at the side, and it is probable the upper parts of the sides of the car will be formed of slats, so as to give good light and ventilation.

The new office building of the Philadelphia & Westchester Traction Company, at Llanarch, is now completed and ready for occupancy. The building is 32 ft. x 45 ft., built of brick with slate roof, and is very artistic in appearance. It contains, in addition to the superintendent's office, a spacious waiting room for patrons of the road, and a room for the use of the motormen and conductors, the latter being provided with lockers, in which the men can keep their uniforms, etc., if they so desire. This room also contains a table with magazines and periodicals. The basement of the building will be used as a storage room for electrical supplies.

The general offices of the Chattanooga Electric Railway Company have been moved from the Market Street car shed to the new transfer station between Fourth and Fifth Streets, on Market Street. The company is engaged in making extensive improvements in its system, and is adding a number of handsome cars.

The Fort Wayne Street Railway Company maintains a swimming pool at Robinson's Park, which is controlled by the company. Hans Reitdard, while swimming with other boys, dove against a stump concealed in the pool, and was so severely stunned as to cause him to drown. His mother brought suit for $10,000 against the company, alleging carelessness in not removing the obstruction, and that by reason of such negligence her son's death occured. The case was tried at Auburn, and the jury, after being out two days, awarded her $500 damages.

The Marion County Tax Board has fixed the assessment of the reorganized Indianapolis Street Railway Company at $3,000,000. General Manager McGowen claimed that in view of the heavy drain on the company by the cost of improvement, together with the direct tax of $30,000 a year to the city, the assessment was too large. He says he will go before the State Board of Tax Review and ask for a reduction. The county board fixed the company's assessment last year at $2,200,000, and the State board raised it to $3,000,000.

The Boston Elevated Railway Company has placed a contract with the Westinghouse Electric & Manufacturing Company for a 4000-h.p. generator, to be installed at Lincoln's wharf.

The Massachusetts Electric Companies have leased the eight-story building at 14 Kilby Street, Boston, and will occupy the premises at once as a general office.

The cars of the New York & Queens County Railway Company, of Long Island City, carry large colored placards showing the right and wrong way to alight from the car. At one side of the card is pictured a young lady in the act of stepping easily to the ground with her face toward the motorman; at the other is a stout dame in the act of turning a somersault on the pavement, with her packages flying in all directions. The lettering accompanying the pictures reads simply: "How to Get Off and How Not to Get Off a Trolley Car." It is thought these signs have prevented numerous accidents.

A car belonging to the Brooklyn Rapid Transit Company was nearly destroyed by fire on July 15. A short circuit caused the flames.

A short circuit burned out one of the transformers in the big electrical power houses in Buffalo Avenue on July 15. The flame communicated to a small tank on the subway floor that supplies oil to the machinery. It took the firemen an hour to extinguish the blaze. The transformer that was burned supplied power to the Buffalo & Niagara Falls Railway, the Gorge Road and the Niagara Falls & Suspension Bridge Road. Cars on these lines were stalled for two hours. The loss, it is stated, will be large.

The State Railroad Commissioners of New York have authorized the Long Island Railroad to discontinue eleven stations in Brooklyn, where the traffic has been nearly all taken away by electric and elevated cars running in the streets. A new station will be established to take the place of three others that are to be discontinued.

The Columbus (Ohio) Street Railway Company has decided on a profit sharing distribution to employees in the same proportion that stockholders receive. The only stipulation is that employees must have been in continuous service for six months. The company has just declared a quarterly dividend of 1 per cent.

The wages of the laborers employed by the Columbus Street Railway Company in relaying its tracks have been increased twenty-five cents per day.

The Cincinnati Street Railway Company will divide among its motormen and conductors about $10,000 as a 5 per cent dividend, thus enabling the employees to share in the profits of the past year.

In order to prevent accidents due to persons putting their heads out of car windows and coming in contact with poles and other obstructions near the track, the Twin City Rapid Transit Company is putting netting in all the windows of its closed cars, along the side nearest the centre of the street.

To encourage pleasure riding the Janesville Street Railway Company, after seven o'clock every evening during the warm weather, will carry passengers around the entire system for five cents, provided they do not leave the car. The same ride usually costs ten cents.

The Columbus Street Railway Company has published a very artistic guide to the city of Columbus. This contains a number of splendid engravings, and tells how to reach all points of interest.

Hambleton & Co., of Baltimore, and New York capitalists are about to complete plans for a purchase and consolidation of the street railways of Chattanooga and the two incline roads to the summit of Lookout Mountain. It is estimated that the deal will involve about $800,000.

The "Leader," of Marion, gives the following list of proposed electric railways to be built in Indiana this season: Indianapolis Street Railway Company will build a line from that city to Greenfield; an electric line from Hartford City to Indianapolis, passing through Noblesville. This road is to be built the coming summer. It will be 46 miles long, and estimated to cost between $300,000 and $400,000; an electric line from Evansville to Rockport, Tell City and Cannelton; an electric line between New Castle and Indianapolis; an electric line between Richmond and Eaton, Ohio; an electric line between Richmond and Muncie; an electric line between Columbus and Terre Haute; an electric line between Ft. Wayne and Indianapolis; an electric line between Aurora and Rising Sun; extension of the Monon from Greencastle to the Indiana coal fields; an electric line to connect Garret, Auburn, Waterloo, Ashley, Hudson, Pleasant Lake, Angola and Ft. Wayne.

The Mayor of Minneapolis has vetoed the ordinance passed recently by the City Council authorizing the Twin City Rapid Transit Company to run through fast cars between Minneapolis and St. Paul. It was the intention to build side tracks along the line and place in service a number of special cars that would make the trip without stops and reduce the running time twenty-four minutes. The fare was to have been fifteen cents on these fast cars instead of ten cents, the regular fare. The Mayor in his veto message said: "There is little doubt that such a fast service as is here proposed would be a convenience, and were the interests of all the citizens properly guarded, there could be no objection to it. In its present form, however, the ordinance is open to the objection that it contemplates a backward step in the relation of public service corporations and municipalities. This is especially apparent when the municipality volunteers an advance in fares in the absence of a showing of loss, or even a failure of reasonable profit on present rates.

Merger of Electrical Manufacturing Companies

Although not officially announced, there seems to be little doubt that the Sprague Electric Company and the Stanley Electric Manufacturing Company will shortly be brought together in a close union of interests amounting to a consolidation. It is practically certain that a director in the Sprague Company is as an individual the purchaser of the Stanley Company, and Henry Hine, of the Stanley Company, has assumed the management of both companies. The control of the Stanley Company will put the Sprague Company in an exceedingly strong position for a general electrical business, inasmuch as it will now be able to manufacture alternating current apparatus for transmission of power under the Stanley patents, direct current generators and motors of the largest types, designed by Mr. Sprague and Mr. Lundell, and apparatus required for the Sprague multiple unit system of train equipment.

The complete list of officers of the Sprague Electric Company is as follows: President, A. B. Chandler, president of the Postal Telegraph Company; first vice-president, John E. Searles; second vice-president and technical director, Frank J. Sprague; general manager, Henry Hine.

The Chicago Convention of 1899

John M. Roach, general manager of the Union Traction Company, of Chicago, who will doubtless be made chairman of the local committee of arrangements in place of the late M. K. Bowen last week authorized a representative of the Street Railway Journal to state emphatically that the local street railway companies were working in great harmony. That the plans for entertaining the members of the American Street Railway Association had been outlined, and that the work from now on would be pushed with great vigor. He stated that the street railway companies of the country and the representatives of manufacturing and supply houses could rest assured that they would receive as cordial a welcome, and find as ample and satisfactory accommodations for entertainment and exhibits as had ever been accorded them at any previous convention.

The secretary of the association also states that all the space in the exhibition hall has already been applied for and assigned, but that additional space will, if necessary, be provided or the original allotments be cut down to provide for later applicants.

The Detroit Situation

The Michigan Supreme Court, on July 5, decided that the McLeod law, authorizing the appointment of the Detroit Street Railway Commission was unconstitutional, that there is no such office as the Detroit Street Railway Commission, and that Governor Pingree and the other commissioners have no title thereto.

The court based its opinion almost wholly on the proposition that the law is in contravention of a section of the State Constitution which provides that "the State shall not be a party to or interested in any work of internal improvement, nor engaged in carrying on any such work, except in the expenditure of grants to the State of lands or other property."

In spite of this decision Governor Pingree and Mr. Johnson endeavored to force through the Detroit Common Council the "Security Franchise," the principal features of which were described in the last issue of the Street Railway Journal. The bill was passed by a small majority, but was promptly vetoed by the Mayor. This action was followed by a determined effort on the part of Mr. Pingree and Mr. Johnson to pass the bill again through the Council over the veto. Charges of bribery were freely made, and the people were greatly aroused. Near the end of the struggle the Detroit companies announced an "object lesson" in 3-cent-fare opera-

tion by putting all the lines in the city on this basis. The bill was finally defeated, and a communication was sent by Mr. Johnson to the Street Railway Commission reading as follows:

"We are satisfied that it is not feasible to consummate, under existing conditions, the plan of transferring the street railway property to your company. We must face squarely the proposition which the opponents of the plan put forward, that our franchises are running out, and that when they do expire we shall have an expensive plant on our hands which the opponents of the plan say they can compel us to sell at a ruinous sacrifice unless we are willing to accept a new franchise on their terms. We must so manage the railways in the meantime as, if possible, to prevent the loss so threatened. Low fares and short franchises are incompatible if railways are to be run for profit as a private enterprise."

This communication is held to indicate an intention on the part of the Detroit companies to return to a straight five-cent fare, abolish tickets and transfers, and endeavor to make the most money possible out of the property during the remainder of the franchise term.

"The Other Side"

Allen Ripley Foote is editor of a new weekly paper entitled "The Other Side," which is published at 126 Market Street, Chicago, and in which will appear arguments and statistics upon questions of municipal ownership of public service industries, in general supporting private ownership. The publication will be found extremely useful and valuable to all who wish to get a clear idea of municipal ownership problems which are coming up for consideration in many cities, and Mr. Foote's well-known ability and long study of public questions of this character are a sufficient guarantee that the reading columns of "The Other Side" will be carefully and well edited.

Street Railway Complications in Atlanta, Ga.

The recent consolidation of the Atlanta Consolidated Street Railway Company and the Atlanta Railway Company under the title of the Atlanta Railway & Power Company has resulted in a complicated fight over franchises between that company and the Collins Park & Belt Railroad Company, which was not included in the consolidation. This, the only opposition railway in Atlanta, at present a suburban road 10 miles long, has been purchased by a syndicate, at whose head is H. M. Atkinson, president of the Georgia Electric Light Company, which corporation has the exclusive contract for street lighting, and until recently has furnished the power for operating the Atlanta Railway Company's lines. The Collins Park & Belt Railroad Company has elected the following officers: J. Simmons, president; H. M. Atkinson, vice-president, and F. M. Zimmerman, superintendent. Mr. Zimmerman has been, during the past year, superintendent of the Atlanta Railway Company, until the formation of the Atlanta Railway & Power Company.

The Collins Park Line has made application to the City Council for franchises over a large number of the most important streets, and consulting engineers who have recently been in Atlanta have laid out a system of 27 miles of track, which will enter into nearly all of the territory now served by the Atlanta Railway & Power Company, and, in fact, crosses that company's lines in about thirty places. Suburban lines have also been surveyed, which parallel the Railway & Power Company in many places.

In the meantime, a fierce newspaper controversy is being waged between H. M. Atkinson, of the Collins Park Company, and Joel Hurt, ex-president and chief stockholder of the Atlanta Railway & Power Company. Mr. Atkinson claims that there is a good opportunity for profitable investment in the new proposed lines, which he expects to operate in connection with his present power plant.

Mr. Hurt, on behalf of the Railway & Power Company, has made the announcement that the latter will begin shortly the construction of a power house to cost $750,000, so as to enter actively into competition for municipal and building lighting, and states that they will be prepared to furnish electricity to the city for streets, manufactories and buildings, and in addition will furnish steam, heat and cold air. They also state that the buildings now occupied by their present power house will be converted into a car manufactory, and active competition will be made for the Southern street car and truck trade.

The latest development in the struggle is the application through the courts for an injunction against the Atlanta Railway & Power Company to restrain them from connecting with or operating the lines formerly controlled by the Atlanta Railway Company, to dissolve the consolidation with that company and to prevent them from abandoning certain portions of lines that formerly competed in the same territory. A temporary injunction has been granted. The courts are also requested to place the properties under a receiver and prevent the transfer of stock.

Storage Batteries in Washington

The new Washington Traction & Electric Company has just placed contracts for ten storage battery cars to be run on the Anacostia & Potomac River Division. These cars are to be practically duplicates of the cars now running in Chicago. Old trolley cars of the system will be changed over to provide for the batteries, and Westinghouse motors and the chloride batteries of the Electric Storage Battery Company will be used. There are several practical reasons for putting storage batteries upon this line. The Pennsylvania Railroad is going to elevate its tracks in that section, and the territory is such that it is not at present safe to go to the expense of putting in an underground electric system. Moreover, it is desired to make a practical experiment of storage battery cars under Washington conditions, with the hope of using them on other lines as feeders. The batteries will be charged from terminals carried in a vault in the streets. Two of these cars may possibly be used on the P Street loop.

Patent Office Report

The report of the United States Patent Office Commissioner for the year ending June 30, 1899, advance copy of which has just been received, shows this department of the government to be in better condition than ever before in its history. A summary of the different tables contained in the report is as follows:

There were received in the last fiscal year 35,352 applications for mechanical patents, 2292 applications for designs, 91 applications for reissues, 1610 caveats, 1861 applications for trade-marks, 612 applications for labels and 112 applications for prints; a total of 41,930 applications. There were 23,550 patents granted, including reissues and designs; 1406 trade-marks, 372 labels and 76 prints were registered. The number of patents that expired was 16,670. The number of allowed applications which were by operation of law forfeited for non-payment of the final fees was 4021. The total receipts of the office were $1,209,554.88; the total expenditures were $1,148,663.48, and the surplus of receipts over expenditures, being the amount turned into the treasury, was $60,-891.40.

Steam Railroad Statistics

The Interstate Commerce Commission at Washington reports the following statistics concerning the steam railroads of the United States, for the year ending June 30, 1898: On June 30, 1898, the total single-track mileage was 186,397 miles, this being an increase of 1968 miles for the year. The total mileage, including single tracks, second, third and fourth track, yard track, sidings, etc., was 247,533 miles, an increase of 4088 miles. The total number of railroad corporations was 2047. On the above date there were 36,234 locomotives, of which 9956 were passenger, 20,627 were freight and the rest switching, etc.; 1,326,174 cars, of which 33,595 were passenger, 1,248,826 were freight and the rest special cars for officials, etc. This does not include cars owned by private individuals or companies. There were 874,558 employees, an increase of 51,082.

The amount of capital outstanding on June 30, 1898, not including current liabilities in the term, was $10,818,554,031. This amount equals $60,343 per mile of line. The amount of capital which existed in the form of stocks was $5,388,268,321, of which $4,269,271,714 was common stock, and $1,118,996,607 was preferred stock. The amount which existed in the form of funded debt was $5,430,285,710, comprising mortgage bonds, $4,640,762,632; miscellaneous obligations, $486,977,279; income bonds, $262,194,688, and equipment trust obligations, $40,351,111. The aggregate number of passengers carried during the year was 501,066,681, an increase of 11,621,483.

The gross earnings of 184,648 miles of steam roads for the year were $1,247,325,621, an increase of $125,235,848; operating expenses were $817,973,276, an increase of $65,448,512; earnings from operation were $429,352,345, an increase of $59,787,336; deductions from earnings were $427,235,703. The total dividends declared were $96,240,864.

Organization of a New Manufacturing Company in Great Britain

A prospectus of the British Westinghouse Electric & Manufacturing Company, Limited, was issued in London under date of July 10. The capital is to be £1,500,000, of which £1,000,000 are in 6 per cent £5 preference shares, and £500,000 in £10 ordinary shares. Preference shares have priority in distribution of assets and are entitled to a non-cumulative preferential dividend at the rate of 6 per cent per annum on the amounts paid up, together with one-quarter of the surplus profits of each year available for dividend after payment of 6 per cent on the ordinary shares, the remaining three-quarters to go as additional dividend on the latter.

The Westinghouse Electric & Manufacturing Company, of Pittsburgh, receives the entire issue of ordinary shares in consideration of certain contracts and agreements referred to below; £500,000 of the preference shares are offered to the public, of which £150,000 have been subscribed by the vendors and their friends and allotted in full.

The directors are J. Annan Bryce, late director of the National Construction & Armaments Company, Ltd.; C. W. Benson, Joseph Lawrence, chairman of the Linotype Company, Ltd., and chairman of the Machinery Trust, Ltd.; Hon. R. Clere Parsons, M. I. C. E., A. I. E. E., late partner in the firm of Kitson & Co., Leeds; George Westinghouse, president of the Westinghouse Electric & Manufacturing Company, and Lemuel Bannister. As technical adviser, the company will have the invaluable services of Lord Kelvin, F. R. S. The secretary is Arthur E. Scanes, and the company's temporary offices are at Cornhill Chambers, 63 Cornhill, E. C.

The prospectus states that the company has been formed for the purpose of establishing works for the production of every description of electrical machinery and appliances on a larger scale than any now existing in Great Britain, and thus meeting a demand that has hitherto been largely supplied from foreign sources. With this object an agreement has been made with the Westinghouse Electric & Manufacturing Company, whereby valuable rights for the United Kingdom, its colonies, possessions, protectorates and dependencies (except those in North America) are secured to the British company.

The American Company agrees to transfer to the British company its patents for the territory above mentioned, and further, for a period of ten years, to communicate all improvements it may make, and supply all plans, specifications and information necessary to conduct its manufacturing operations to the best advantage. The British company, by availing itself of the accumulated experience and technical assistance of the American company, will thus avoid heavy experimental expenditure in establishing its business.

The orders for plant and appliances for the British company's territory for the year ended June, 1898, are certified by the vendors to the board at £130,613, and for the year ended June, 1899, at £266,528. Recent orders and inquiries indicate a progressive increase. The American company returns the output of its Pittsburgh factory for the year ending March 31, 1899, at £1,428,474, and its net profit thereon at above £255,000, these figures being subject to final audit. In view of the constant increase of orders and the profitable nature of the business, the Pittsburgh works are in course of being approximately doubled.

The agreement contains provisions for mutual support and protection between the companies, for the immediate turning over to the British company of the existing business relating to the above-mentioned territory, including the orders on hand, which will at once form a source of revenue, and for the supplying by the Pittsburgh factory at wholesale prices, less agreed discounts, of all apparatus, appliances and accessories which the British company may require until the factory in England is in working order. The British Company will thus start as a going concern. The American company guarantees that the profits resulting from the business for the first two years shall amount to a sum not less than sufficient to pay the dividend upon the amounts called up on the preference shares during that period, so that pending the completion of the factory, which is estimated to take eighteen months at the outside, the 6 per cent to the preference shareholders is assured.

A site, covering about forty acres for the proposed works, has been agreed for at Trafford Park, Manchester, where water and railway communications are excellent. The situation is about the center of the manufacturing districts, where skilled labor is plentiful and where the demand for electric apparatus will be great.

Mr. Westinghouse and Mr. Bannister, who have been for many years associated with the business, have joined the Board of the British company.

The present issue of capital will suffice for the construction and equipment of the works as now proposed, but if the contemplated success is achieved, the land acquired will accommodate larger premises, and further capital will have to be from time to time provided.

The consideration payable has been fixed by the American company, and consists of the 50,000 ordinary shares issued credited as fully paid. It will pay all costs, excepting only government and stamp duties, in connection with the formation and registration of the British company down to the allotment of the preference shares now offered. The entire proceeds of such preference shares will therefore be available for the business.

Opening of a New Niagara Bridge

On Friday, July 21, the new suspension bridge of the International Traction Company, connecting the United States and Canada, over the Niagara River was formally opened with appropriate ceremonies. The new bridge forms a link in the international belt line which it is proposed to establish around the Niagara Gorge and Whirlpool. The most important factor in the belt is the Niagra Gorge Railroad, which starts at Prospect Park, Niagara Falls, and runs through the gorge at the water level, furnishing the only means of access to the immediate vicinity of the Whirlpool and rapids. At Lewiston a switch leads to the new bridge, which crosses to Queenston, Ont. The cable span of the new bridge, now the only suspension bridge across the Niagara, is 1040 ft.

At the Canadian end the Niagara Falls Park & River Railway, controlled by the International Traction Company, ascends a heavy grade to Queenston Heights and runs thence along the bluff on the Canadian side of the upper steel arch bridge, across which cars have been run for the last year. This brings the car back to within less than 1000 ft. of the starting point, and the Niagara Reservation Commission has been asked to grant permission, under a recent act of the Legislature, for the laying of tracks along the riverway, connecting the upper bridge and the Gorge Road tracks in Falls Street. It is understood that this permission will be granted early in August, allowing the completion of the international belt line. A traffic agreement has been made between the Niagara Gorge Railroad and the Niagara Falls Park & River Railway for the sale of round trip tickets good for the complete circuit. This will benefit both roads, but the Gorge Road has less to gain than its Canadian rival, which is now able to add to the inducements to travel on it the possibility of returning via the Gorge.

Organization of the Tramway and Light Railways Association in Great Britain

There has just been organized and registered under the Companies' Acts the "Tramway and Light Railways Association," for the promotion of tramway interests in Great Britain, along lines similar to those of the American Street Railway Association. The articles provide that the governing body of the association shall be a president, a vice-president, a council of not more than eighteen members, the first members to be appointed by the signatories to the articles of the association. In accordance with this provision the following gentlemen have been nominated as the first members of the council: George Richardson, Esq., chairman of the North Metropolitan Tramways Company, Belfast Street Tramways Company, Blackpool and Fleetwood Tramroad Company, etc.; George F. Fry, Esq., member of the Tramways Committee of the Dover Corporation, chairman of the London Street Tramways Company, director of the Belfast Street Tramways Company, etc.; Emile Garcke, Esq., managing director of the British Electric Traction Company, chairman of the Potteries Electric Traction Company, chairman of the Swansea Improvements & Tramway Company, etc.; J. Barber Glenn, Esq., director of the London Street Tramways Company, managing director of Provincial Tramways Company, secretary of the Belfast Street Tramways Company, Isle of Thanet Light Railway Electric Company, etc.; W. M. Murphy, Esq., chairman of the Dublin United Tramways Company, director of the Belfast Street Tramways Company, London Southern Tramways Company, etc.; Stephen Sellon, Esq., Parliamentary engineer of the British Electric Traction Company, director of the Potteries Electric Traction Company, etc.

A. M. Wilcox, editor of the "Railway World," has been appointed honorary secretary, and William Morris, Jr., of the firm of Ashurst, Morris, Crisp & Co., has consented to act as honorary solicitor. The membership will consist of companies of the tramways departments of municipal corporations, and of individuals. Each individual member will have one vote, and every corporation or company will have five votes.

Solid Wrought Forged Axle Box Frames vs. Riveted Patchwork Truck Frames

BY JOHN A. BRILL

In the June and July issues of the STREET RAILWAY JOURNAL are two articles on the fundamental principles of an electric truck, signed by Edgar Peckham. These articles are essentially an attempt to reply to an article by me published in the May issue of the STREET RAILWAY JOURNAL. Mr. Peckham very adroitly begs the question, and at the same time entirely avoids the points which I made in the discussion of the "Parallel in the Development of the Locomotive and the Electric Truck." In that article I did not mention any "make" of truck, but my effort was entirely directed towards showing the fallacy of a patchwork truck frame, which he, very naturally, thinks it is necessary to defend. His statements relating to plate frames in locomotives, as compared to bar frames, are wholly misleading. The bar frame is essentially American locomotive engine practice, and was found necessary because of the formerly inferior roadbed construction. The plate frame is a European type of construction, and the plates are cut out of a single piece of metal; this is the case also of the pivoted or bogie trucks used on European railways. There could be no question about some value of Mr. Peckham's truck if, instead of a patchwork made up of a multitude of rods, bars, castings and rivets, he would follow the English and Continental locomotive practice, as recited above, and cut the side frames of his truck from a single plate of metal.

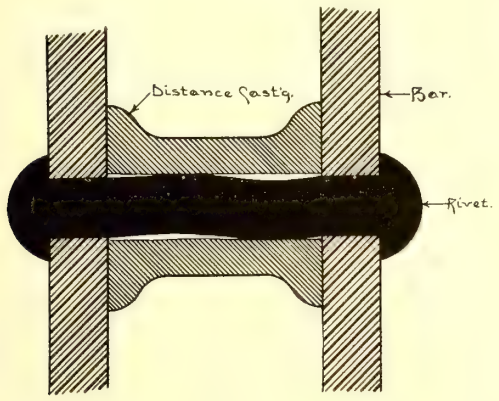


FIG. 1.

FIG. 2.

It is rather surprising to be told that locomotive frames have no weight to carry, and that engines weighing from 120,000 lbs. to 140,000 lbs. "put no strains upon their frame beyond those produced by the propelling mechanism." In English and American locomotive frames, whether of the plate or bar pattern, rivets are conspicuous by their absence. Riveted joints are nowhere able to stand such straining and pounding as trolley car trucks or locomotives give their frames. Then, too, the reference to bridges and riveted structures is not to the point. Riveted bridges, he seems to think, are strong and in every respect analogous to a locomotive or an electric truck. This indicates a radical failure to comprehend the mechanical principles involved. A bridge, it is true, has heavy loads to sustain for a few minutes; it is subjected to a certain amount of vibration in a vertical direction only; but there is no comparison between its work and the hammering which a truck or locomotive frame receives during all the time of service. Whereas a bridge is subjected to a violent strain vertically for a few moments during the passage of a train, and then remains at rest for a very much longer interval of time, a truck frame is subjected to stresses in every possible direction, and the pounding which it receives is almost unparalleled in mechanics. Riveted bridges are not considered as fine structures as the type known as the "pin" connected, and the repairs upon them and upon such structures as elevated roads are sufficient demonstrations of this. The weakness of riveted structures made up of a multitude of parts, combining cast iron, cast steel, bar iron and rivets, is shown in every direction, particularly in trucks over bridge work, because in the trucks the spacing blocks are cored out, whereas the holes in the bars are either punched or drilled. When the parts are riveted the rivets buckle to a large extent, if the hole in the spacing block is large, as shown in Fig. 1 herewith, and under heavy strains allows the rivet to stretch or bend. In this particular riveted truck work differs essentially from that of riveted bridges, especially plate girder bridges, because the plate girders have no spacing blocks, and the plates are placed together, drilled and riveted, under which process the rivets, fitting snugly in all holes, have no chance to buckle.

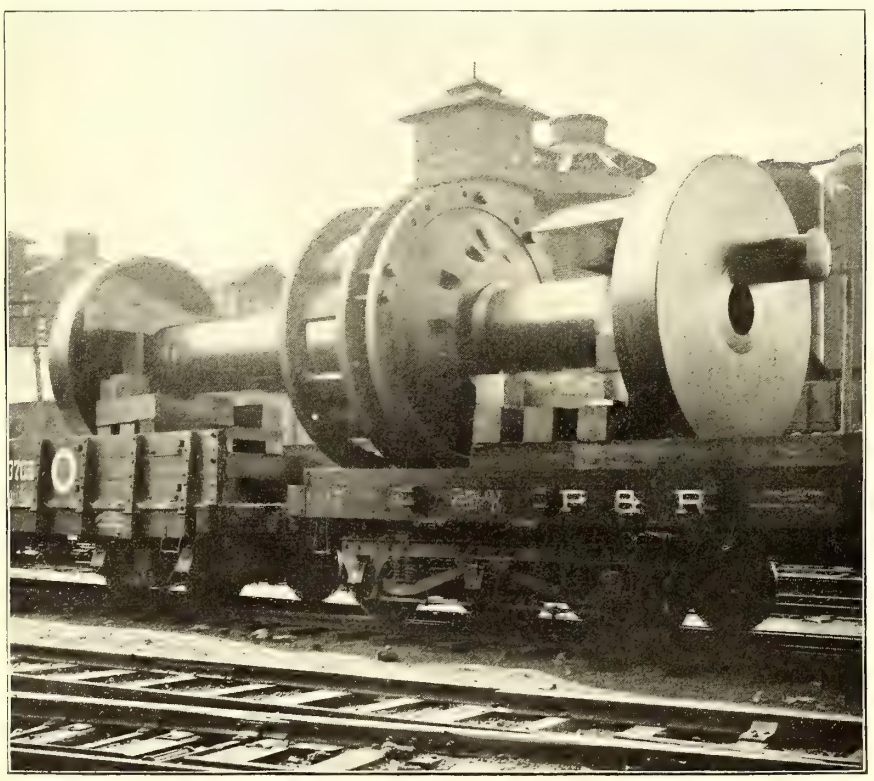
The difference between bridge work and truck work is illustrated in the accompanying sketches. A rivet driven in two bars separated by a distance piece does not fill the hole, and presents in section the appearance shown in Fig. 1. In bridge or boiler work plates with drilled holes come solidly together, and the rivet is capable of filling the hole, as shown in Fig. 2. The distinction is a radical one. Manufacturers of trucks with this type of side frames have always been obliged to concentrate their attention upon holding up the load, as they have been obliged to use the truss under most unfavorable conditions as to support and submit it to strains for which it is in no wise suited. The inevitable result is the sagging of the car ends. With solid forged frames or a plate bar frame of sufficient size of section the ends of the cars would more likely have stayed in place.

Mr. Peckham entitles the article which he is writing in defence of the composite frame truck "The Functions of the Electric Truck." In his two instalments he makes no mention of these functions. In his writing he as completely ignores them as he does in his construction. The pith and point of his article seems to be that "I can build a fine truss that will hold up the ends of a car." The reply to this is that there is no difficulty whatever in holding up the ends of a car, or there ought not to be, although Mr. Peckham seems to have encountered no end of trouble in this line. The truss of which he speaks and of which he appears to be so proud is one that he has but recently introduced, and is not a part of the frame of his truck, but is a direct copy of a truss the J. G. Brill Company has used for years, and was employed by it on its open horse cars; it is also the same class of truss which the company put on the first motor truck which was ever built.

Mr. Peckham distinctly says that the solid frame trucks are being replaced by those of his own manufacture. I wish to say in reply to this surprising statement that I have yet to learn of a place where such a thing is happening. So far as I know, it has not happened in the past except in one case five years ago, and there the Peckham trucks were not a success, while the discarded ones were purchased by other lines, and are in good condition and operation to-day.

It should be understood that when I undertook to discuss the developments of the electric truck or its frame I was not attempting to consider the matter of building a separate and independent truss for sustaining the ends of long cars. In holding up the ends of cars Mr. Peckham has been as peculiarly unfortunate as he was in the choice of a design for his truck frame. The truck side which he is now making is the same old style that he built in 1892, and is of a type which the Brill Company at that time discarded because of its inherent weakness. Because of this weakness and inability to hold up the ends of a car, he has been obliged to devise what he terms the "new truss," and several thousands of his trucks are now in operation without this truss upon which he lays so much stress. The composite truck side which the J. G. Brill Company built in 1892, and the side which Mr. Peckham builds at present contain all the inherent weak points of the composite locomotive frame of 1832. The J. G. Brill Company thought then, as Mr. Peckham thinks now, that the horizontal stresses were comparatively insignificant. These horizontal stresses are so great that the truss and riveted truck sides shake to pieces and allow the end of the truck to drop, taking the end of the car with it. With the best riveting machines possible, and the most careful attention to every detail of workmanship, the riveted structure is unable to stand the strains of street railroad work. Even after seven years of experience and constant failure, this fact does not seem to have impressed itself upon Mr. Peckham. The "trusses" are simply names to conjure with. They are mere selling points, and are of no value except as such, and as means to cover up weaknesses which are a part of the bad original designs.

The quotation which Mr. Peckham makes from an article by Henry E. P. Cottrell is merely an effort to draw attention away from the main question. I am very glad that Mr. Peckham has called my attention to this article, as I propose to answer it, and set the public straight in regard to this matter. A long car body and a truss for holding its ends up are questions entirely outside of the truck. One truss can be just as easily applied to a car as another. It is the truck side which is defective, and no matter how well the ends of a car may be trussed, the truck side, by reason of the multitude of parts, soon gives out under the stresses and hammering, its ends drop, it ceases to hold the axles in line, and it then becomes an expensive failure. My article was written for the purpose of bringing clearly before the minds of street railway men the fundamental principles of good truck construction. It seems unfortunate to attempt a discussion of principles which are not important, and to undertake to defend one maker's trucks by the application of an outside element which has nothing to do



with truck building, because the long truss does not effect the riding qualities of the truck. It does not decrease the pitching nor steady the body in any way, nor strengthen a weak truck side, yet these ideas are persistently advanced in Mr. Peckham's article.

Sale of an Ohio Road

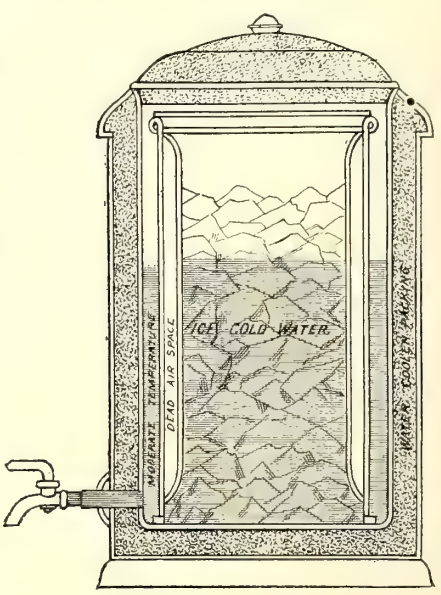
The entire assets and property of the Newark & Granville Electric Street Railway Company, of Newark, Ohio, will be sold at receiver's sale on Aug. 26, 1899. This system consists of about 8 miles of road in the city of Newark, which has a population of over 22,000 and about 7 miles of road, extending from Newark to Granville, a college town of about 3000 population, with one of the finest parks in the country along the road near the city of Newark. It is equipped with first-class machinery and cars.

Large Engine Shaft for Boston

On June 9 there was made from the works of the Bethlehem Steel Company, at South Bethlehem, Pa., what is thought to be the second largest shipment ever made in this country, the largest having been the Krupp gun, which was transported by the Pennsylvania Railroad Company, between Sparrow's Point, Md., and the World's Fair, Chicago. The illustration shows the shipment referred to. It is a shaft with crank discs and generator fly-wheel hub assembled on it, all finished complete. This shaft was made for an engine built by the Corliss Steam Engine Company, of Providence, R. I., for the Boston Elevated Railway. The total

LARGE ENGINE SHAFT FOR BOSTON

weight of the shipment was 170,400 lbs., and in order to transport it from South Bethlehem to the site at Boston, Mass., the Philadelphia & Reading Railway Company furnished two cars of 100,000 and 80,000 lbs. capacity respectively and blocked the shaft so that 60 per cent of the weight was supported on the stronger car and 40 per cent on the other. The shipment was made over the New Jersey Central, the Delaware & Hudson Canal Company and Boston & Albany Railroad Company.



The shaft is the first of three for the Boston Elevated Railway. It is of fluid compressed nickel steel, hydraulically forged hollow on a mandrel, oil tempered and annealed. It is 37 ins. diameter in the center, with a 17-in. hole through its axis, and is 27 ft. 10 ins. long. The metal of which it was made showed tests of 50,000 lbs. elastic limit and 18 per cent elongation in test pieces 1 in. diameter and 10 ins. long. Shipments, approximating this size, will frequently have to be made by railroads in the future.

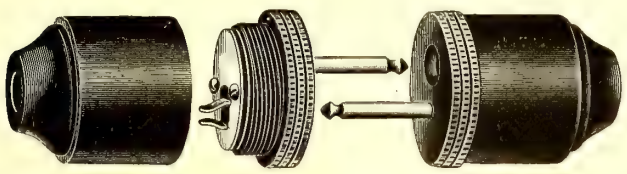
The Bethlehem Steel Company has in hand orders from the Edward P. Allis Company, Milwaukee, Wis., for the Metropolitan Street Railway Company, of New York city, eleven shafts of exactly the same size, also from the Westinghouse Machine Company, Pittsburgh, Pa., orders for sixteen similar shafts for the Third Avenue Railway Company, of New York city, and two for the Brooklyn Edison Illuminating Company, also from the Westinghouse Electric & Manufacturing Company, Pittsburgh, orders for fifteen shafts a little smaller in size for the water power plant at Messina Springs, N. Y. The power plants for which these shafts are intended are designed to be equipped with engines of 8000 h.p. capacity. In all probability even larger units than this will be called for in the future, as the tendency toward centralization of power is in that direction. It is stated that the engines for the power plant, made necessary by the change from steam to electricity by the Manhattan Elevated Railway, New York city, will have a maximum capacity of 12,000 h.p. The shafts for these engines will, of course, be considerably larger than that shown in the illustration.

Receptacle for Water Cooler

A scientific ice-water receptacle for holding drinking water in waiting rooms, on street cars, in offices, etc., is being placed on the market by A. Major, of New York city. For this device is claimed a saving of 50 per cent in ice, and in addition a more agreeable temperature for the water than is obtained by simply putting a piece of ice in water in an ordinary cooler. The water is kept at a uniform temperature, resembling very closely that of cool spring water.

The new device is very simple, consisting of an independent receptacle, open at the bottom, as shown, and having double walls, with a dead air space between them. It also has a double cover. This receptacle is designed to be placed in any cooler, and should be about 1½ ins. smaller all the way around than the cooler in which it is to go. The ice is placed in the inside vessel, which, having no bottom, permits the water to circulate in and around it, keeping, it is claimed, the water from getting extremely and unnecessarily cold, and preventing the ice from melting as rapidly as it ordinarily would. Mr. Major, whose address is 461 Pearl Street, has succeeded in introducing his invention quite successfully throughout the United States. The receptacle is made in any size to fit any cooler.

NEW WATER COOLER



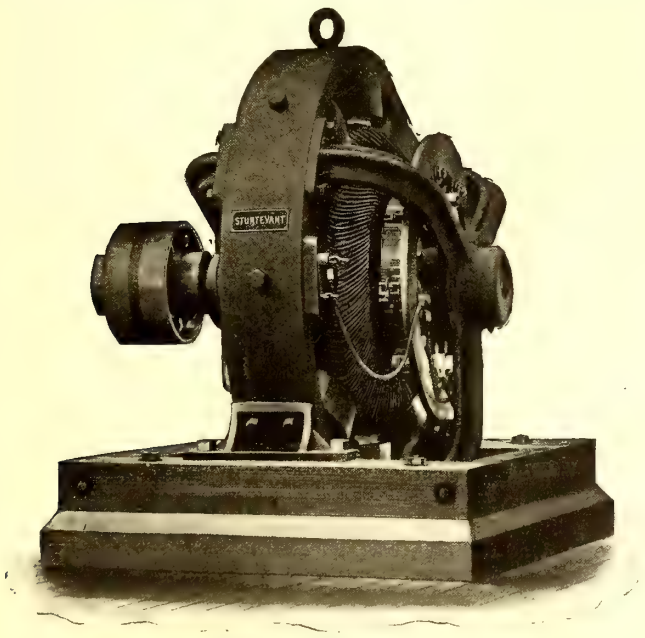
Tickets for Tramways

A good idea of the extent of the tramway business is obtained by a glance over the catalogue of T. J. Whiting & Sons, of London, manufacturers of tramway tickets. This company has been engaged for a long time in the business of printing tramway tickets for all parts of the world, and its catalogue contains reproductions of these tickets. They include tickets from cities throughout Europe, Asia and Africa and in all languages, including Chinese and various dialects of Hindoo. The catalogue gives an excellent idea of the firm's world-wide connections and reputation.

Electric Trailer Connector

At this period of the year there are varying calls for train capacity, through picnics, trolley parties, baseball games, etc. This means frequent additions of trailers to motor cars. Safety of connecting current devices doubtless is more sought for by electric railway managers than articles giving ease of operation. A combination in one device of these two elements makes it of greatest usefulness. The Wood's trailer connector, as illustrated herewith, is claimed to possess these qualities. It has the particular advantage that at no time (after connection to lighting circuit) is there any exposure of live metal, the connecting pins being absolutely "dead" until beyond the reach of the conductor's fingers. This safety factor also is worth noting as applying to inquisitive or careless passengers.

The Wood's trailer connector, as well as a complete line of electric railway supplies, is carried by the Central Electric Company, Chicago, as selling agents for the Central Union Brass Company, St. Louis, Mo.



CONNECTOR FOR TRAIL CAR

New Type of Dynamos and Motors

The B. F. Sturtevant Company, of Boston, has made a specialty of the construction of eight-pole generators and stationary motors, running in size from 3 kw. to 110 kw. The motors of this type were designed originally for driving fans for subway work, and their use in the Boston subway has been described in the STREET RAILWAY JOURNAL. They have been found, however, so economical and desirable that the Sturtevant Company has increased the number of sizes in which these motors are built, and recommends them not only for ventilating, but for general power purposes about car houses and power stations.

The field ring, which also constitutes the frame of these machines, is of wrought iron in the small, of cast steel in the medium, and of cast iron in the large sizes. The field cores are of wrought iron, and the pole shoes of cast iron, of such peculiar shape and size as to render these machines capable of meeting extreme variations of load without sparking or the necessity of adjustment.

NEW MULTIPOLAR DYNAMO

The field coils are machine wound, thoroughly insulated, and of such open construction as to secure the maximum radiation and ventilation. The armature core is built up of laminated slotted discs, which are solidly clamped between two brass rings having corresponding slots. The coils are machine wound, of uniform size and shape, and thoroughly insulated, the armature being of the drum type.

The commutator is of large diameter, the segments being of fine rolled or drop-forged copper. For high voltages or small outputs at low speeds two sets of reaction brushes, of fibre-graphite, are usually employed, and from the character of the design require no adjustment. Tripod bearing yokes are provided, as shown above, except in the largest machines, which are equipped with special bases and pedestal bearings. The shaft runs in gun-metal sleeves, and is lubricated by means of ring oilers.

Water Guards for Trolly Poles and Ropes

The accompanying illustrations show a water guard invented by Thomas Hawken, superintendent of the Rockland, Thomaston & Camden Street Railway, of Rockland, Maine. The guards are made of rubber, and that on the trolley pole is intended to keep the rain from running down the pole and also the rope. That on the rope protects the rope only and rear platform, and when the car is in motion the water drops clear of the car. The method of application is clearly shown in the engravings.

GUARD ON POLE

GUARD ON ROPE

It is not necessary to use both of these devices, but, as some managers or conductors would prefer to have the device on the rope and others on the pole, Mr. Hawken makes both types. The guard has been given a severe test for several months on the Rockland, Thomaston & Camden Railway, and has given perfect satisfaction.

Large Sales of Boiler Cleaning Device

The Union Boiler Tube Cleaner Company, of 240 Penn Avenue, Pittsburgh, Pa., was organized in 1895 for the purpose of introducing an entirely new industry, that of removing scale from the interiors of the tubes of water tube boilers, and it is one of the largest concerns of the kind in the world, having machinery especially designed for this specific business. Its devices are patented abroad, as well as in the United States, which enables this company to safely contract for thoroughly cleaning boilers under a time limit, with bond for heavy penalty for non-fulfillment, or to sell or lease tools for cleaning all makes of water tube boilers having straight, horizontally inclined or vertical tubes and those having curved tubes, such as the Climax, Stirling, also the Hazelton, having closed end tubes, the latter three types having been heretofore considered impossible to clean.

This concern commenced business as a firm May 1, 1895, a time of great depression in the industrial world, notwithstanding which the evident merits of its devices caused their immediate adoption in a number of the power plants in the United States and England. The continued demand for these cleaners has compelled the manufacturers to greatly enlarge their works, despite which the factory is overcrowded with orders.

Large Orders for Registers

The business of the New Haven Car Register Company is constantly increasing, and the company reports a large number of new orders. Of its recent large orders one is for several hundred machines for the Third Avenue Railroad Company, New York city. The company has also received large orders lately from St. Joseph, Mo., and additional orders for its registers for the Market Street system, of San Francisco, from Oakland and Los Angeles, Cal., in both of which cities its registers are in use.

Large Sprinkling Car

Wendell & MacDuffie, of New York City, have sold during the past summer three sprinkling cars, which are said to be of larger capacity than any ever before built in this country. Two of these

END VIEW OF SPRINKLING CAR

were sold to the North Jersey Street Railway Company, and one to the Philadelphia & Westchester Street Railway Company. The tank cars were manufactured by the Taunton Locomotive Manufacturing Company, of Taunton, Mass.

In the accompanying illustrations one of the cars furnished to the North Jersey Street Railway Company is shown. The tank proper is 24 ft. long and about 64 ins. in diameter. The car is mounted on Peckham 14-B double trucks, and is equipped with Van Dorn couplers, North Jersey Street Railway Company's standard bumpers, and Sterling brakes, in accordance with specifications. The tank is completely housed in, there being four dummy windows fitted with curtains. The sprinkler has a total capacity of 4000 gals. of water.

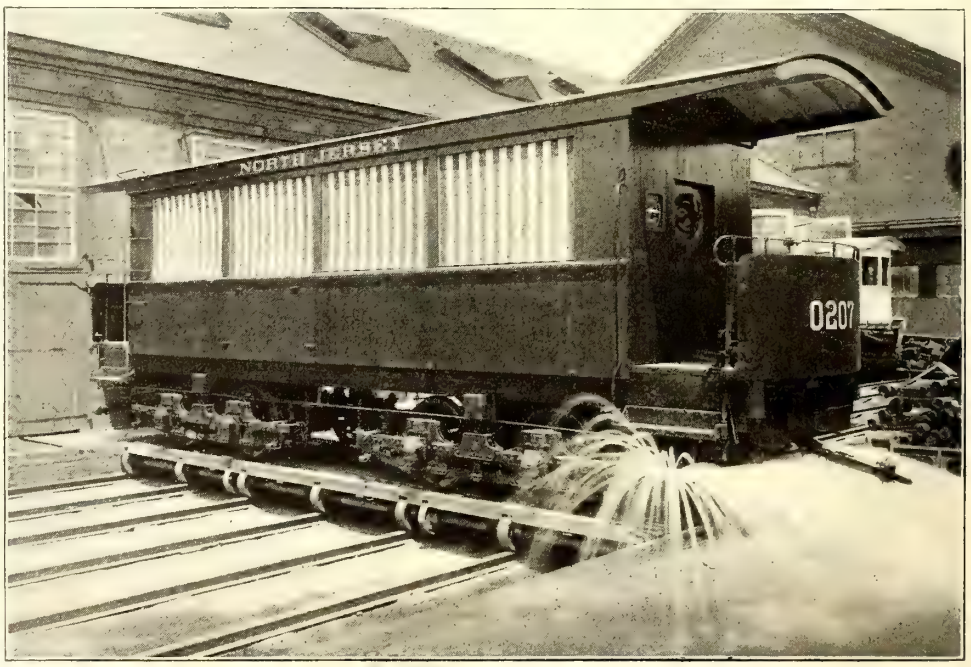
A Handsome Catalogue

The Gold Car Heating Company, of New York, has recently published a very tasteful catalogue of its various types of car heaters for steam and electric railways. Mr. Gold has made a life study of the heating of cars, and the list of railroads whose cars he has equipped with heating apparatus is a most extended one, and includes roads in all parts of the world. Altogether about 20,000 cars and locomotives have been equipped with the Gold system.

As is well known, the Gold Car Heating Company manufactures both steam and electric heaters. In the latter, which is the type, of course, in which electric railway managers are most interested, special attention has been given to securing a good circulation of air around the heated wires and distributing the heat in a uniform manner through the car. The degree of heat can be regulated by a three-point switch. The company also makes electric heaters for car house and miscellaneous uses.

The catalogue is very fully illustrated and is handsomely printed.

A Successful Car Fender



The Hipwood-Barrett fender, a test of which was described in the July issue of the STREET RAILWAY JOURNAL, is exciting a well-deserved interest among street railway officials. When the fender is dropped to the ground by a slight action of the motorman's knee, its construction is such that it conforms perfectly to any unevenness in the roadbed, by means of the five distinct sections. As these have a resilient action, there is no danger of stubbing, and a tension holds them close to the roadbed. The tests have shown it to be infallible in picking up a body, no matter in what position it may be standing or lying on the track. These features also prevent impairment of efficiency by oscillation of the car.

Attached to the sections are lips just forward of the bed, which, allowing a body to readily pass over them when being picked up, successfully prevent its falling back on to the track again, and continued tests have proved the adjustment of the tension to be such that snow, ice or mud cannot possibly interfere with the action. The fender is folded up and disposed of under the car when a trailer is to be used or a disabled car pushed along, or when housing, which, taking but three seconds to accomplish, will recommend its use to all railroad men.

New Road in Wisconsin

On July 4 the cars on the Waupaca & Chain o'Lakes (Wis.) Electric Railway were started for the first time. The building of this road has been in contemplation for the past two years, but only recently were the franchises secured and financial arrangements made. The contract for the entire construction and equipment, including track and overhead work, cars and equipments, was awarded to the Electrical Installation Company on May 18 last. Work on the grade was started May 26, and cars put in operation, as above stated, July 4, thus making thirty-two working days for the entire building of 5 miles of road complete. No better record than this can be shown in the United States, especially in this year of never-ending delays in delivery of apparatus and materials.

One of the features of this remarkably fast piece of work was

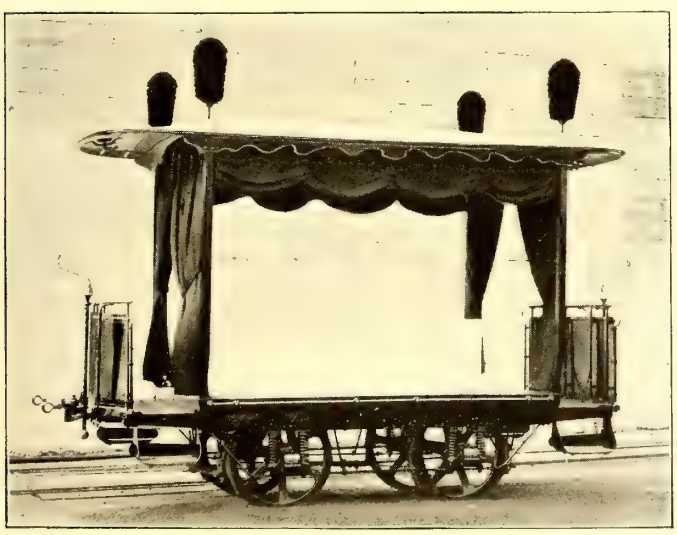
SIDE VIEW OF SPRINKLING CAR

the laying, lining and surfacing of 23,000 ft. of track in sixty working hours. Had it not been for delay in receipt of special work for track the line could have been open for traffic June 25. The road is built on standard lines throughout, using cedar ties, 50-lb. T rail, crown bonds and 00 trolley wire with both span and bracket construction. The city end of the line is ballasted with stone, the suburban portion with gravel for its entire length. This road reaches one of the most delightful spots in the State of Wisconsin, and opens up a new territory such as cannot fail to make the road a paying investment. W. B. Baker and Irving P. Lord are the owners of the line.

Compressed Air Cars in Chicago

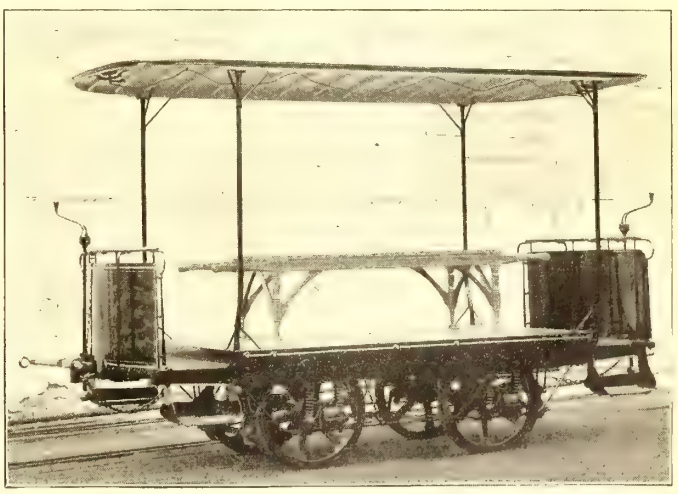
The Compressed Air Motor Company, of Illinois, with headquarters at Chicago, reports that it placed in operation on May 30, 1899, one of its compressed air motor cars, replacing one of the horse cars in the night service of the North Clark Street Cable Railway. It is stated that this car has performed a continuous service, carrying passengers each night without failure or delay, and, it is said, entirely with satisfaction to the street railway officials. Since May 30 an additional compressed air car has also been put on, and air cars are now doing the "owl" service between the City Hall and the city limits.

On the first and second trips at night one or two trail cars are attached to the motor car, and in a single round trip of 7 miles 417 passengers have been carried.



Patent Litigation

The Thomson-Houston Electric Company has been granted preliminary injunctions restraining the Worcester & Clinton Street Railway Company from infringing claims 20, 21, 22, 27, 28, 29 and 31 of Letters Patent No. 393,323, covering a system of electrical controllers, and claims 3, 4, 11, 19, 20, 23, 25, 26 and 27 of Patent No. 424,695 granted to Van Depole, and covering a suspended switch.

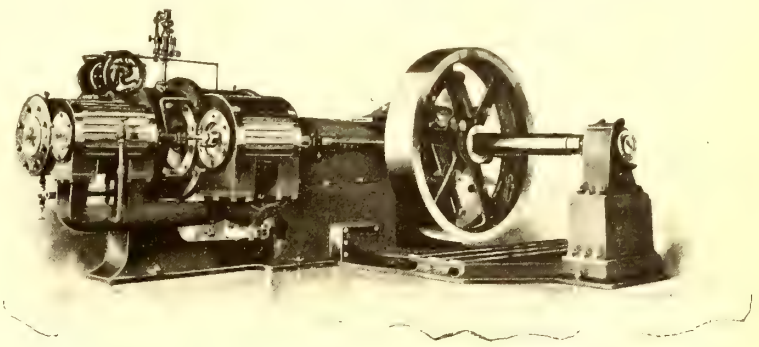


The Thomson-Houston Electric Company has also been successful in its suit against the Central Union Brass Company for infringement of the Van Depole Patent No. 424,695; and also against the Mill Creek Valley Street Railway Company for infringing Patent No. 393,323.

Open Funeral Cars

The Mexicans of all classes have a very sensible idea about the utilization of their street railways for transportation of funerals. In America a few steam railroads provide funeral facilities, but the idea of using the ordinary street car, whether propelled by animal power or electricity, does not seem to have been carried out to any great extent in America. The two cars illustrated were built recently for the Cia Tranvias de Merida Yucatan by the J. G. Brill Company. The road is narrow gage and is operated by animal power. The cars are but 9 ft. long by 6 ft. in width over all. One of them is of the plainest possible sort, merely a platform carrying a bier with a light roof supported by four rods at the corners. The other one is somewhat more elaborate, draped curtains at the corners and an enclosed bier in the center are provided, while the roof is decorated with plumes. A small crucifix is placed in the center of each roof. The inside of this car is finished in white and gold. The cheaper car has the ordinary carlin finish. The casket can, of course, be placed in the car from either side. For the mourners the ordinary horse cars are provided, and, as the cemeteries are made termini for the roads, the system is one which is in every respect sensible.

FIRST CLASS HEARSE



SECOND CLASS HEARSE

A Well Known System of Compound Engines

Although it is but a comparatively short time since the practicability of a short-stroke, quick-acting, wheel-governing compound engine has been admitted by the leading engineering talent, the demand for such engines is now very extensive and is constantly increasing, and under proper operating conditions the economy of the compound engine is unquestioned.

Recognizing these conditions, the Harrisburg Foundry & Machine Works, of Harrisburg, Pa., has developed a complete system of engines of this nature, one size of which is shown herewith. In this design the low pressure cylinder is placed next to the engine frame, since this method insures a more substantial attachment than otherwise, and the high pressure cylinder, with the generously proportioned connection between them, has a bracket support which rests upon the end of the sub-base, which extends the full length of the engine. The bottom of this bracket support is planed with a tongue, which is fitted accurately in a corresponding groove in the top surface of the sub-base, bolts being provided in longitudinal holes, thus allowing expansion and contraction, but preventing any lifting tendency. Ample opportunity is provided for repairing or adjusting the piston and rings without having to detach the high pressure cylinder, piping, connections, etc., this being a most important consideration.

REAR VIEW OF ENGINE—GENERATOR REMOVED

The receiver, between high and low pressure cylinder, is a neat flanged casting with bolt attachment. The larger sizes are built with separate valve connections, whereby the high pressure valve is automatic in action, and the low pressure valve is driven by a fixed eccentric, so arranged, however, that the cut-off may be set by hand at any desired point. In this way, it is claimed the most economical results possible can be obtained under almost any changing conditions. A further advantage is obtained in this regard by the arrangement of the heads of the piston valves, which are adjustable, and so may have both "lead" and "lap" changed also to suit any and all conditions. The engines are provided with the Ideal automatic oiling system, and in closely graduated sizes, from 25 h.p. to 1200 h.p. The accompanying illustration shows the engine arranged for direct connection to generator. Belted styles are, of course, also built. There are already nearly one hundred of the Harrisburg engines of this style in operation.

New Method of Welding Rails in Germany

Herr Dr. Goldschmidt, chief chemist of the experimental laboratory of Essen, has invented a new method for welding street car rails, which is described as follows:

The Goldschmidt method for the production of high temperatures, as applied to the welding of street railway rails, has been tried on portions of the Essen Street Railway, after the possibility of the welding of rails of the Phœnix, or grooved section, of 180 mm. (7 ins.) height had been thoroughly demonstrated in the laboratory. The practical application of the principles are identical with the experimental. The rail ends, which must be perfectly square and thoroughly clean, are firmly forced together by a special clamping device. The general construction of this apparatus, of which several types were made and tried, consists of several cast steel pieces, which securely hold the rail ends in both a vertical and horizontal position, making it easily transferable from one joint to another. The total space it occupies when in position at the joint is about 80 mm. x 50 mm. x 30 mm. (3 ins. x 2 ins. x 1.2 ins.) When sufficient pressure has been secured the joint to be welded is covered by a sheet-iron casing, corresponding to the contour of the rail surface, and the whole covered with sand. The welding process proper is now ready to take place.

The welding compound, which is composed of pulverized oxide of iron and aluminum, is prepared in and poured from a crucible by means of long tongs.

A small portion of the compound is ignited in the crucible by means of a fuseé (zundkirsche), and the remainder is gradually brought around it so that the ignited portion is completely covered. Finally, a coating of fluid corundum appears, which radiates intense heat and a brilliant light. A residual metal settles in the bottom of the crucible. Inasmuch as the top layer of this corundum solidifies rapidly, it is necessary to remove it by means of an iron rod just before pouring. At first the fluid metal will run into the mould and cover the joint with a thin, hard coating. The corundum solidifies at a temperature considerably higher than that of the iron to be welded. When the metal that collected on the bottom of the crucible begins to flow, this coating referred to above prevents it from coming in contact with the rails and thereby injuring them. The sheet-iron form is also protected in this way, and permits its use over and over again. On cooling, the whole mass can be easily removed, on account of its brittleness, by being struck with hammers. During the application of this intense heat at the joint the metal expands, but, owing to the presence of the clamp, still greater pressure is caused, and the result is a perfectly sound weld, as has been demonstrated by breaking tests. A bending test, made by loading a joint with a weight of 45,000 kg. (99,000 lbs.), with supports 70 c.m. (27.6 ins.) apart, showed a permanent set of 2 c.m. (0.79 ins.) only, but a rupture occurred considerably later, by the application of a live load.

The entire work of welding a joint on the track can be accomplished by the aid of three men in a few moments. By using this device all cumbersome machinery is eliminated, the only necessary requisites being the metallic compound, which can be shipped in barrels; clamps, crucibles and a few other small utensils, thereby reducing the cost of transportation to a minimum. The cost of this operation is such that it can easily compete with the old method of fish-plates and copper bonding as a means of effecting a rail joint.

The New Street Railway Management in Washington

Col. George Truesdall, ex-Commissioner of the District of Columbia, and for many years closely identified with the business and public interests of Washington, has been elected president of the Washington Traction Company and of the street railway companies which it controls. The other officers of the properties are Charles A. Lieb, of New York, vice-president; H. D. Merrick, treasurer; James B. Lackey, secretary, and V. B. Deyber, assistant treasurer. The new directors are George Truesdell, O. T. Crosby, Charles A. Lieb, S. C. Stevens, George W. Young, Nathaniel Wilson, James B. Lackey, V. B. Deyber and H. D. Merrick.

Col. Truesdell is a native of Fayetteville, N. Y., but has lived in Washington for many years. He has been prominently connected with the city's real estate development, particularly in the suburbs, and is said to have been the original projector of Eckington and builder of the Eckington & Soldiers' Home Railway Company, which was one of the first electric railways in the country, and the first to use center-pole construction. Largely through the building of this road and the excellent results thereby given to the district, the property greatly increased in value, and houses were built so rapidly as to make this one of the most populous of Washington's suburbs. Col. Truesdell served as District Commissioner for three years under the Cleveland administration.

Street Railway Conditions in St. Petersburg

The street railways of St. Petersburg are single track lines, operated by horses, with double deck cars, of which three are usually run together. By the terms of the franchises the roadbed and rails become the property of the city on the expiration of the charter, the other property to be purchased by appraisement. The city has had possession of and has been running the best line, about ten miles long, for a year, and a suit is now pending to get possession of the remainder of the system. The city intends to equip the Nevsky Street Car Line with some electric system, but details have not yet been decided upon, and a number of interests are endeavoring to secure contracts. Belgian capitalists have been particularly active in their attempts to obtain contracts and franchises.

Personal

MR. H. A. JONES has been appointed secretary of the Oswego Traction Company, of Oswego, N. Y.

MR. JOHN A. WILSON has been appointed chief engineer of the Trenton Passenger Railway Company.

MR. FRANK J. SPRAGUE sailed for Europe on Wednesday via steamship St. Paul, to be gone for about six weeks.

MR. P. H. KING has been appointed manager of the Montgomery & Chester Electric Railway Company, of Montgomery, Pa.

MR. J. L. YOUNG, JR., is the new auditor of the Richmond Traction Company of Richmond, Va., taking the place of Mr. J. A. Cook.

MR. GEORGE W. MOFFAT has resigned his position as superintendent of the Doylestown & Willow Grove Trolley Road, of Doylestown, Pa.

MR. A. K. BAYLOR, general manager of the British Thomson-Houston Company, has arrived in America, where he will remain until about Sept. 10.

MR. WM. J. BURNS, general manager of the West End Traction Company, of Pittsburgh, died on June 16, 1899, in Paris, France, where he had been staying for his health.

MR. A. G. CARLSON, chief draughtsman of the Chicago City Railway Company, sailed for Europe on July 12 for a short recreation trip. He will visit Sweden before he returns.

MR. ROBERT P. LINDERMAN has been elected president, Mr. E. M. McIlvain vice-president, and Mr. R. W. Davenport general superintendent of the Bethlehem Iron Company.

MR. G. F. GREENWOOD, formerly general manager of the Consolidated Traction Company, Pittsburgh, will, it is stated, go to Cuba this fall to reconstruct the street railways in Havana.

MR. W. B. BROCKWAY, secretary of the Toledo, Bowling Green & Fremont Electric Railway, has been placed temporarily in charge of the system, owing to the death of President Jacoby.

MR. SAMUEL G. BOYLE has been elected secretary and treasurer of the Louisville Railway Company, of Louisville, Ky., to succeed Mr. James Pettus, who retires on account of ill-health.

MR. DANIEL T. HUNT has succeeded Mr. Charles T. Yerkes as president of the North and West Chicago street railway companies, which are leased to the Chicago Union Traction Company.

MR. EDWIN JACOBY, president and treasurer of the Toledo, Bowling Green & Fremont Electric Railway Company, and a prominent business man of Toledo, died last week after a short illness.

MR. J. HOWARD WILSON, president and general manager of the Mobile Light & Railway Company, of Mobile, Ala., has resigned his position to look after private business interests in New York.

MR. J. E. WOODBRIDGE, editor of the American Electrician, was married to Miss Ethel Hotchkiss, of New York, on July 25, at Grace Church. He and his bride left soon after the ceremony for Chicago.

MR. THEODORE STEBBINS, vice-president and manager of the Schenectady Railway Company, of Schenectady, N. Y., has been succeeded in that position by Mr. R. H. Fraser, of Des Moines, Iowa.

MR. W. R. CASSELS, who has been for many years connected with the electric lighting interests of Buenos Aires, Argentina, was in the United States, during July. He will return to Buenos Aires, via London.

MR. J. M ATKINSON, well known in street railway circles in connection with the Atkinson protected rail bonds, was married on June 21 to Miss Elizabeth Amolia, at the First Presbyterian Church, of Lynchburg, Va.

MR. C. C. JOHNSON, secretary and superintendent of the Raleigh (N. C.) Electric Company, has been appointed manager of the Ithaca (N. Y.) Street Railway Company, and will assume his new duties about July 15.

MR. A. K ASHWORTH has retired from the office of manager of the Youngstown Park & Falls Street Railway Company, of Youngstown, Ohio, and has been succeeded by Mr. Robert T. Ivory, formerly track superintendent.

MR. JOHN GRAHAM, the retiring general manager of the Wilkesbarre & Wyoming Valley Traction Company, of Wilkesbarre, Pa., was tendered a banquet on June 23, by his friend and business associate, William J. Harvey.

MR. N. GRABURN, assistant superintendent and electrical engineer of the Montreal Street Railway, has been appointed to the position of electrical superintendent of the Glasgow (Scotland) Tramways, and will leave Canada within a few weeks.

MR. P. A. B. WIDENER, the well-known street railway financier, of Philadelphia, is president of the National Export Exposition, which intends to hold a very extensive national exhibit of manufactures, in Philadelphia, from Sept. 14 to Nov. 30, 1899.

MR. H. J. MALOCHEE, of New Orleans, under whose supervision the Orleans Railroad of New Orleans was rebuilt, has been appointed constructing engineer of the Huntsville Electric Railway, of Huntsville, Ala., and material will be ordered and work begun at an early date.

MR. A. C. RODENBOUGH, who has accepted the superintendency of the Easton, Palmer & Bethlehem Electric Railway, of Easton, Pa., in connection with his present duties as superintendent of the Easton Transit Company, has appointed Nathan Capon division superintendent.

MR. J. H. PASSMORE, of Reading, Pa., will, on July 1, assume the duties of manager of the Schuylkill Valley Traction Company, of Norristown, Pa. Mr. A. G. Davids, formerly manager of this system, has resigned, and will go to Gloucester, N. J., to take charge of a railway at that place.

MR. WILLIAM KELLY, JR., has been appointed general passenger agent for the Niagara Gorge Railway Company. Mr. Kelly has been for some years the general Eastern passenger agent of the Chicago, Milwaukee & St. Paul Railroad, and is secretary of the Buffalo Passenger Association.

MR. GEORGE E. SCRANTON, superintendent of transportation of the Columbus Street Railway Company, of Columbus, Ohio, will leave on Sept. 20 for Havana, Cuba, where he will assume the direction of the construction of a street railway system to be built by a syndicate of Eastern capitalists.

MR. JOHN E. SEWELL, general manager of the Waterbury (Conn.) Traction Company, has been appointed general manager of the Connecticut Light & Power Company, with headquarters at Waterbury. This is the company recently formed by the consolidation of several Connecticut electric railway and lighting systems.

MR. CHARLES G. BURTON has accepted a position with the Chicago office of the Westinghouse Electric & Manufacturing Company. Mr. Burton has had an active electrical career, having originally been with the Brush interests, and later with the Central Electric Company, of Chicago, and the Sprague Electric Company, at Chicago.

MR. EUGENE CLARK, formerly superintendent of the Plank Road line of the North Jersey Street Railway Company, of Newark, N. J., has been succeeded in that position by Mr. James McDonough, who has had charge of the South Orange line. Mr. P. McDermott, of Jersey City, takes Mr. McDonough's place on the South Orange line.

MR. H. N. HURT has been appointed superintendent of the Atlanta Railway Company, of Atlanta, Ga. Mr. Will Glenn has been appointed assistant superintendent and purchasing agent, and Mr. N. W. L. Brown has been appointed superintendent of construction. These gentlemen hold similar positions with the Atlanta Consolidated Street Railway Company.

MR. M. F. H. GOUVERNEUR, who was formerly manager of the Wilmington (N. C.) Street Railway Company, and later on of the Yonkers Street Railway Company until its consolidation with the Union Railway Company, of New York city, has just accepted a position as general manager of the Mobile Light & Railway Company, of which Mr. J. H. Wilson is president.

MR. HORACE B. ROGERS has been chosen manager of the Brockton & East Bridgewater Street Railway Company and the Brockton, Bridgewater & Taunton Street Railway Company in place of James W. Shaw, resigned. Mr. Henry Reynolds has been elected secretary and treasurer. These changes are made in consequence of the consolidation of the two companies.

MR. W. E. COOKE, formerly connected with the Peckham Motor Truck & Wheel Company, and the Walker Company, is now in Perth, Western Australia, constructing a tramway for the Deep Leads Company, which owns several mining properties in Australia. Mr. Cooke reports the country a fine one, with conditions which do not differ very greatly from those found in America.

MR. and MRS. PHILIP DAWSON of London, who have been traveling in America for some two months, sailed for London via steamship "Trave," on July 25, having made a host of new friends as well as renewed many old ones. On July 24 Mr. and Mrs. Dawson gave a farewell luncheon at Delmonico's to their friends in New York and vicinity, of whom about twenty were in attendance.

MR. ALLEN R. FOOTE, the well-known authority on street railway legal and financial matters, has recently undertaken the publication of a new weekly paper, known as the "Other Side." It will be the object of this periodical to give the current views and expressions of writers and thinkers on both sides of such questions as treat on the relations of the public to quasi-public institutions.

MR. JOHN LUNDIE, whose office has been for some time in the Empire Building, has removed to 925 Exchange Court Building, 52 Broadway. Mr. Lundie's report to the Boston Elevated Railway Company, covering the cost of train service at different speeds, schedules, etc., has been presented to the company, and Mr. Lundie is now engaged on other important special work in a similar line.

COL. C. F. MORSE has retired from the position of president and treasurer of the Metropolitan Street Railway Company, of Kansas City, Mo. At the annual election of this company the following officers were elected: President, W. H. Holmes; vice-president, L. E. James; general manager, Conway F. Holmes; treasurer, W. E. Kirkpatrick, of Chicago, and general superintendent, W. A. Saterlee.

MR. GEORGE C. DRESSEL, president of the Dressel Railway Lamp Works, of New York, died July 3. He was born in Germany in 1828, and learned the trade of coppersmith. He came to this country when he was still a young man and entered the employment of the New York & Harlem Railroad, where he remained for eighteen years. In 1881 he began the manufacture of railroad signal lamps.

MR. C. R. HEAP, of London, the British representative of the C. & C. Company, of New York; the Wagner Company, of St. Louis; the Partridge Carbon Company, of Sandusky, and other American concerns, has been in America on a business trip for some time, and sailed by the New York on July 12. He reports that the business in Great Britain for American apparatus is very large and is constantly increasing. He has placed orders for apparatus to a considerable amount in America.

MR. S. L. NELSON, general manager of the Springfield Railway Company, of Springfield, Ohio, took occasion, upon the celebration of the fortieth anniversary of his birthday, which occurred June 23, 1899, to present each of the employees of the company with which he is connected with different sums of money, ranging from $1 to $10, as a token of his appreciation of their faithful services. The gifts amounted in all to over $600. The men in turn, to show their regard, presented Mr. Nelson with an elegant leather-covered chair and a number of small silver articles.

MR. S. W. CHILDS has charge of the construction of the Perth Tramways at Perth, Western Australia, immediately under Mr.

W. E. Cooke. Mr. Childs was engaged for some time in the United States in railroad construction work, having been connected with the building of the street railway systems at Brooklyn, Columbus, Ohio; Baltimore and Charleston, S. C. At the latter place he had full charge of the construction of the entire system, including the building of about 30 miles of track, erection of power house, car barns, etc. In 1893 he accepted a position with J. G. White & Company, and is now in Perth as their representative.

MR. LOUIS J. MAGEE, managing director of the Union Elektricitäts Gesellschaft, of Berlin, who went to Germany from America some years ago, has just been given special and very unusual honors in being elected one of six directors of the Association of German Electricians (Verbund Deutscher Elektrotechniker). Over this directory Herr von Siemens presides and Gisbert Kapp is general secretary. The association, which is seven years old, has 2395 members. Mr. Magee was instrumental in forming the Union Elektricitäts Gesellschaft in 1892, to take up the Thomson-Houston business for a large part of Europe and European and Asiatic Russia, and has become widely known in Germany and other countries as an engineer and business man.

MR. EDWARD B. WYMAN and MR. ALLEN H. P. STONEHAM, of London, were in the United States last month for a short visit. Both of these gentlemen are prominently connected with the Deep Leads Electric Transmission Company, of Victoria, Australia, and with the Perth Tramways at Perth, Australia. Mr. Stoneham is managing director of several, and director in a number of large mining companies in Victoria, Western Australia, British Columbia and other parts of the world. He is the chief owner of, and individually financed the Perth Tramways. He is also interested in a number of power transmission properties in different parts of the globe. Mr. Wyman is the managing director of the Deep Leads Transmission Company, and the Victorian Deep Lands, Ltd., and a director of the Kalgoorlie Power syndicate. He is an American, and was engaged for several years in the electric heating business in the United States. In addition to his connection with the Deep Leads enterprise he is interested in several other mining projects.

MR. J. B. CAHOON, general manager of the Elmira Municipal Improvement Company, which operates the electric railway, lighting, gas and waterworks of that city, has resigned his position in order to accept that of general manager of the Syracuse Underground Electric Wiring Company, which controls the franchise for underground wiring in Syracuse, and has also a franchise for operating an electric plant. The new company is composed of Messrs. William L. Elkins, Stephen Peabody, Henry Seligman, Hollister & Babcock, Robert C. Pruyn and local capitatlists, and will have a capital of $500,000, nearly all of which will be spent immediately in putting up a new electric lighting plant. Mr. Cahoon is a graduate of the Annapolis Naval Academy, class of 1879. In 1889 he became connected with the Thomson-Houston Company, and organized the expert department of the General Electric Company after the consolidation in 1894. He later became chief engineer of the local companies committee, and at different times had charge of thirty-seven electric lighting and two street railway properties owned by the General Electric Company. He went to Elmira in 1895, where his record has been exceptionally good.

AMONG THE MANUFACTURERS

THE UNION TRACTION COMPANY, of Philadelphia, is making some tests with the Christensen air brake on its York Road line.

C. W. MOFFETT has taken the management of the Boston office of the Heine Safety Boiler Company, of St. Louis, in place of Russell Walker, recently resigned.

W. H. WISSING has been appointed general agent for Nagle, Holcomb & Company, of Chicago, and will have his headquarters at 642 Century Building, St. Louis, Mo.

R. W. BLACKWELL & COMPANY, of London, have been successful in the suit brought against Greenwood & Batley, Ltd., of Leeds, for £608 15s. 2d., claimed to be due for material furnished.

THE PARRISH SIGNAL COMPANY, of Jackson, Mich., has just finished the installation of a block signal system on the Rochester Railroad, at Rochester, N. Y., which is giving perfect satisfaction.

THE ELECTRIC STORAGE BATTERY COMPANY, of Philadelphia, has published another of its regular bulletins, this one being No. 51. It describes in detail the installation of chloride accumulators in the Dun Building, at New York.

THE MILWAUKEE RAIL JOINT & WELDING COMPANY, of Milwaukee, Wis., has closed a contract for 2000 joints for the Columbus Street Railway Company. The work of installing these joints is to begin during the month of August.

THE PECKHAM TRUCK COMPANY, of Kingston, N. Y., and New York City, was awarded a contract last month for 200 trucks by the Boston Elevated Railway Company. This is in addition to the order given the same company a few months ago.

FRED. H. FITCH, having become financially interested in the Electrical Installation Company, of Chicago, was at a special meeting of the stockholders held June 17, elected a director, and at a subsequent special meeting of the directors elected vice-president of that company.

THE STILWELL-BIERCE & SMITH-VAILE COMPANY, Dayton, Ohio, has been awarded the contract for the turbine wheels for the Virginia Electrical Railway & Development Company. The order calls for four pairs of Victor wheels, the contract price being about $20,000.

THE JOSEPH DIXON CRUCIBLE COMPANY, of Jersey City, has prepared a pamphlet describing in full the new process of brazing by immersion, a process that is particularly adapted to the bicycle trade, but is also applicable wherever the uniting of two metals by brazing is desired.

THE BURT MANUFACTURING COMPANY, of Akron, Ohio, has recently received orders for four Warden oil filters and refiners, from the Alaska Treadwell Gold Mining Company, of San Francisco, for use in Alaska. Two of these were purchased after the first two had been thoroughly tried.

MAYER & ENGLUND, of Philadelphia, the well-known supply dealers, have found their New York business grow so rapidly as to compel them to establish an office in this city. This enterprising firm has therefore opened an office at 85 Liberty Street. It will be in charge of Edward L. Philips.

GEORGE HIPWOOD, of the Hipwood-Barrett Car & Vehicle Fender Company, of New York, has sold the European patents on his car fender to Hermann Romünder. The company will manufacture fenders for the European trade, and will be represented at Cologne, Germany, by Ferdinand Romünder.

THE PROVIDENCE ENGINEERING WORKS, of Providence, R. I., states that the cylinder dimensions of the Greene engines installed by them at the power station of the United Traction Company, of Pittsburgh, are 20 ins. and 38 ins. x 48 ins., and not 28 ins. and 38 ins. x 48 ins., as stated in the last issue.

THE LACLEDE CAR COMPANY, of St. Louis, reports that this has been one of the best and most satisfactory seasons it has ever had. Although its big plant has been running to its fullest capacity the work has nearly all been for its regular customers, who it has endeavored to take good care of by filling the orders with its usual promptness.

THE MILWAUKEE RAIL JOINT & WELDING COMPANY, Milwaukee, Wis., has secured the contract for cast welding 2000 joints for the Columbus Street Railway Company, Columbus, Ohio. The steel jacketed joint which this company is manufacturing has long since proved itself a success, and is meeting with the approval of street railway men everywhere.

THE SHERWIN-WILLIAMS COMPANY, manufacturers of paints and colors, and having offices at Cleveland, Chicago, New York, Montreal and Boston, are sending to the trade a very unique paper-weight, consisting of a very ugly looking animal resting upon an imitation bronze base. This little gift will be appreciated by all fortunate enough to be presented with one.

THE KEYSTONE LUBRICATING COMPANY, of Philadelphia, is receiving proof almost continually of the satisfaction given by the Keystone motor greases, in the shape of testimonial letters from prominent firms, stating they have used and tested these lubricants, and will hereafter use no other brand. One letter states 10 lbs. of Keystone grease lasted a car for two months, during which it ran 8205 miles.

THE CONTINENTAL CONSTRUCTION COMPANY, of Boston, Mass., has just declared a semi-annual dividend of 5 per cent. This company is now building and equipping the Buffalo,

Hamburg & Aurora Street Railway, a Buffalo (N. Y.) suburban line of 22 miles in length. The company gives its whole attention to the building and equipping of electric railways, and has some other good orders in hand.

GATES & RANDOLPH, of Chicago, the new firm of engineers and contractors, have brought out a pamphlet describing a few of the specialties which they handle. These are, improved generators and motors, manufactured by the Triumph Electrical Company, of Cincinnati; the Warren inductor, Empire electric instruments, Scheffer transformers, wattmeters, ammeters, voltmeters, etc., circuit breakers and arc lamps.

A. L. IDE & SONS, of Springfield, Ill., are sending out a catalogue which fully sustains the concern's reputation for careful and painstaking work. The brochure describes the "Ideal" automatic cut-off steam engines, and great care has been taken to make it of real value to engine purchasers. The latter half of the book describes the different parts in detail, cross sections being shown of the cylinders and pistons, cross-heads, etc.

THE WARD-LEONARD ELECTRIC COMPANY, of Bronxville, N. Y., has just issued its catalogue No. 996, devoted exclusively to a description, with price list and cuts, of the Carpenter enamel rheostats. The catalogue contains information regarding 125 different standard forms of field rheostats, all of which are carried in stock by this company. It is noticed the prices quoted are very much lower than those given last year.

THE JOHN A. ROEBLING'S SONS COMPANY, of New York, brought out last month a very pretty Fourth of July souvenir, being a printed and photographic reproduction of the Declaration of Independence, the latter, with signatures appended, and with a beautifully printed cover, showing in antique style an old bell-ringer passing through Philadelphia streets proclaiming the declaration. The whole thing is a charming souvenir well worthy of preservation.

A. L. IDE & SONS, of Springfield, Ill., has filed suit in the United States Circuit Court by Addie F. Ide, Roy W. Ide and Francis P. Ide, executors under the last will and testament of Albert L. Ide, against the Trorlicht, Duncker & Renard Carpet Company, Joseph F. Chuse and Richard Heap. J. F. Chuse is a resident of Mattoon, Ill. The complainants claim to have a patent on improvments in lubricating devices for engines. They pray for an injunction against infringement.

THE HARRISON SAFETY BOILER WORKS, of Philadelphia, Pa., is sending out a neat brochure, which it has been pleased to call "A Peculiar Sort of a Treatise on Feed Water Heaters and Steam Separators." The book, however, sets forth in an extremely forcible manner the claims made for these Cochrane specialties, and it should be in the hands of all steam users who are looking for up-to-date methods of increasing the efficiency of the plants under their charge.

THE CENTRAL ELECTRIC COMPANY, of Chicago, Ill., called attention in its advertisement last month to "The Gem" overhead material, which was also described in the reading columns of the same issue. Through a typographical error in the advertisement the beaded skirt, one of the distinctive features of "The Gem" material, was made to read beaded shirt, and this correction is made in order to stem the flood of orders for beaded shirts which the company is receiving as a result of this error.

THE BETHLEHEM STEEL COMPANY, on the 26th of June formally took over the property, etc., of the Bethlehem Iron Company, of South Bethlehem, Pa., which latter company has leased its works, etc., to the former company. The officers of the Bethlehem Steel Company are: Robert P. Linderman, president; Edward M. McIlvain, vice-president; Abraham S. Schropp, secretary; C. O. Brunner, treasurer; R. W. Davenport, general superintendent; Owen F. Leibert, chief engineer; Charles P. Coleman, purchasing agent.

THE MORRIS ELECTRIC COMPANY is the name of a new corporation just formed as the successor to Elmer P. Morris, of New York. Mr. Morris is treasurer of the new organization, and the business will be carried on largely on the same lines as formerly, with the exception that the company will also engage quite extensively in the manufacture of specialties for the electrical trade. Mr. Morris reports an excellent showing in orders for the last month, particularly in rail bonds. Many contracts have come from foreign countries.

THE SIEGRIST LUBRICATOR COMPANY, of St. Louis, Mo., reports that the Arnold Electric Power Station Company, of Chicago, Ill., after a most thorough investigation of the different kinds of oiling systems, has awarded it the contract to equip the large new power and electric light plant now being erected for the "Imperial Electric Light, Heat & Power Company," of St. Louis, Mo., with the Siegrist "automatic oiling system." This power station is to be one of the most elaborate and perfectly equipped plants in the country.

THE ELECTRICAL INSTALLATION COMPANY, of Chicago, has just completed 5 miles of track and overhead work at Waupaca, Wis., it having had the contract for the complete equipment and construction for the Waupaca & Chain o'Lakes Electric Railroad, which is mentioned elsewhere in this issue. It also has on hand four separate contracts for extensive track and overhead construction for the Metropolitan Street Railway Company, of Kansas City, Mo., as well as additional work for the Vicksburg Railroad, Power & Manufacturing Company.

THE McGUIRE MANUFACTURING COMPANY, of Chicago, is sending out a collection of loosely bound sheets, each one bearing a large half-tone engraving and a short description of some one of the company's specialties. These include the McGuire adjustable traction truck, the No. 39 double truck, the No. 35 motor truck, the solid steel Columbian truck, the No. 28 double frame "L" truck, and the combination snow plow and sweeper. Upon one page appears a list of over seventy-two street railway companies using the McGuire plow and sweeper.

THE SIMONDS MANUFACTURING COMPANY, of Pittsburgh, Pa., announces that it has transferred its Pacific Coast agency from the C. B. Kaufman Railway Supply Company to the Electric Railway & Manufacturers' Supply Company, of 548 Mission Street, San Francisco, Cal. The Kaufman Company has no longer any connection with the Simonds Company, and all communications intended for the latter concern should be addressed either direct to Pittsburgh or to the new agents. A stock of gears and pinions will be carried in San Francisco, as heretofore.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY, Cincinnati, presents in its new catalogue reproductions and descriptions of its apparatus for direct current electric light and power, and particular attention is called to the special applications of its slow speed direct-connected motors, which are shown therein, and in which the company takes pardonable pride. The company's new factory is equipped with the most modern and improved machinery throughout, all electrically driven, and every department is under the most thorough inspection of experts in each particular line.

THE IRONSIDES COMPANY, of Columbus, Ohio, reports activity on all lines of its specialties, both in domestic and foreign trade. Among the products of this company is a special lubricant for gear teeth, that forms a deposit on the working surfaces of teeth, protecting the parts from wear, and incidentally avoiding noise of operation. It is in use by many street car companies on their motor gearing, whose endorsement indicates satisfaction experienced in decreased noise and retarded wear. The Ironsides Company is publishing a series of very readable pamphlets describing its specialties. These include, in addition to the lubricant, boiler scale solvents, gear shields, rope fillers and shields, etc.

THE GENERAL ELECTRIC COMPANY, of Schenectady, has published its usual number of bulletins during the past few weeks, among them being No. 4186, devoted to single-phase alternating current generators, 125 cycles; No. 4187, to artificial light for mills; No. 4188, to electric railway locomotives, etc. The company has also issued from its press a very entertaining little pamphlet entitled "A Trip to the Schenectady Works of the General Electric Company." This last was published for the benefit of the delegates to the recent convention of the National Electric Light Association, and is a brief resumé of the most noteworthy features encountered in a trip from New York to and through the great Schenectady works.

THE CLING-SURFACE MANUFACTURING COMPANY reports rapidly increasing sales, not only in this country, but many orders are being received from Australia, European and South American countries, with a fast growing business in Mexico, all seeming to prove that the truth of the company's motto, "The days of tight belts are over," is being accepted by belt users. A recent letter from the engineer of Brown, Durrell & Co., of Boston, to the company says: "Having tried cling-surface on my 12-in. dynamo belt, I have been able to carry full load with 22-in. sag on belt, with no perceptible slip. It surpasses my expectations, and I can cheerfully recommend it to do all that is claimed for it if directions are followed."

THE NEW YORK SAFETY STEAM POWER COMPANY, of New York, is having excellent success in the manufacture and sale of the Worthington steam boilers, described and illustrated in a recent issue of the STREET RAILWAY JOURNAL. Among the recent orders which this company has received for these boilers are three boilers for the St. Dennis Hotel, New York; two boilers for the Heermance Refrigerator & Cold Storage Company, New York, and boilers for the Hygeia Ice Company, Polytechnic Institute, of Brooklyn; Seminole apartment building, New York, and Grand Union Hotel, New York. The latter has been using two of these boilers for the last six or seven years, and has recently placed an order for a third boiler.

G. A. DENTZEL, builder of steam and electric motive power carousels and organs, of 3635-41 Germantown Avenue, Philadelphia, has recently shipped carousels to the following places: One to Idlewild Park, Pittsburgh; one to Kenwood Park, Pittsburgh; one to Youngstown, Ohio, and one to Parkersburgh, W. Va., in addition to many that were shipped during the winter for the early spring business. He also recently shipped one to Para, Brazil, which has given such satisfaction, and has proved so profitable, that Mr. Dentzel has recently received a letter from the people to whom he sold the carousel, stating that the order would be followed by others in the near future. Mr. Dentzel has also recently placed a carousel in Washington Park, Philadelphia, and Castle Rock Park, near Philadelphia.

THE HARRISBURG FOUNDRY & MACHINE WORKS, Harrisburg, Pa., is to be congratulated upon its new publication entitled "A System of Engines." Although primarily a trade catalogue, the work has been so extended and enlarged as to comprise a very valuable treatise upon the theory and practical operation of the modern steam engine. The book has been published in two editions, one in paper cover for general distribution, and the other handsomely bound in heavy cloth covers, and printed on extra fine paper, and known as the "library edition." This latter will be very extensively circulated, with the compliments of the company, to the mechanical and electrical professions. This company reports its factory is running night and day to keep up with orders on hand, although its present capacity is three times greater than it was in 1897.

JOHN S. NOWOTNY, of 313 East Second Street, Cincinnati, Ohio, announces to the public and his many friends in the electrical business and kindred lines that he severed his connection with the Nowotny Electric Company March 31, 1898. Mr. Nowotny founded the Nowotny Electric Company, and managed the business from its infancy until March 31, 1898. The assignment of the Nowotny Electric Company, which occurred June 30, 1898, in no way affects him. After severing his connection with the above named company he immediately started the manufacture of Nowotny's semi-vacuum long-burning inclosed arc lamps and electrical specialties. The latter business is owned solely by him and operated under his personal supervision and name, and is in no way connected with the Nowotny Electric Company.

THE DUPLEX CAR COMPANY, of New York City, is building cars for the Buffalo, Hamburg & Aurora Street Railway Company, the Ithaca Street Railway Company, the Norfolk Southern Street Railway Company, the Norton & Taunton Street Railway Company, the Bristol County Street Railway Company, Greenville (Miss.) Street Railway Company, Winneconnet (Mass.) Street Railway Company, Allentown & Kutztown Traction Company, Monmouth Traction Company (Pa.), etc, and Duplex cars are going as far away as Honolulu. The Duplex Car Company reports that its representatives abroad have recently visited Armenia, and are making extensive preparations to introduce these cars on the continent. Contrary to some expectations it has been found that it is possible to keep this type of convertible car as warm in winter as the ordinary closed car.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY, of Cincinnati, Ohio, reports June sales as follows: Deere & Company, Moline, Ill.—One 75-kw. moderate speed belt driven generator; Consumers' Park Brewing Company, Brooklyn, N. Y.—two 50-kw. engine type generators, one 7.5-h.p. type "H" motor, one 10-h.p. type "H" motor, two 20-h.p. type "H" motor; Pacific Coast Borax Company, Bayonne, N. J.—one 100-h.p. type "H" motor (375 r.p.m.), one 25-h.p. type "H" motor, one 15-h.p. type "H" motor, one 25-h.p. type "N" motor (back geared); Ruppert Brewing Company, New York—one 100-kw. engine type generator, one 50-kw. engine type generator; Southern Electrical Supply Co., St. Louis, Mo.—one 50-kw. engine type generator, one 25-h.p. type "H" motor, one 12.5-kw. type "H" generator, and many others.

New Publications

Some Glimpses of Elmira. Paper. Illustrated. Published by the Maple Avenue Railroad Company and the West Side Railroad Company, Elmira, N. Y.

This handsomely illustrated pamphlet is a complete street railway guide to Elmira and the surrounding country, and particulars of interesting features in the neighborhood are given. The book contains a large number of advertising pages.

"How Should the Franchise Question Be Settled?" a paper submitted to the League of Illinois Municipalities in 1899, is the title of Part I. of Mr. Foote's able work; "Powers of Municipalities," a paper submitted to the Commercial Club, of Indianapolis in 1898, is the title of Part II.; and "Cost of Service to Users and Tax Payers," a paper submitted to the National Conference of Mayors and Councilmen, at Columbus, Ohio, in 1897, is the title of Part III.

This book is cordially recommended to street railway managers and other students of municipal problems, as an indispensible part of their working equipment.

Practical Electricity. Cloth. 286 pages. Illustrated. Price, $2.00. Published by the Cleveland Armature Works, Cleveland, Ohio.

This book is written throughout by practical men for the purpose of reaching that class of mechanics who are daily called upon to operate electrical machinery without knowing very much of the general construction. The principal feature, which is believed to be original, is the review of each chapter. After the reader has finished a chapter sufficient questions to thoroughly review the subject and to bring out all the important points, are asked at the end of the chapter. These questions the reader must study out and answer for himself, according to his judgment. He can then verify the same by turning to the back of the book, where all answers to questions are given.

Municipal Public Service Industries. By Allen Ripley Foote. The Other Side Publishing Company, 126 Market Street, Chicago, Ill. Cloth. 337 pages. Octavo. Price, $1.00.

Mr. Foote has undoubtedly given more time to the study of municipal problems, particularly those affecting public service industries, than has any other American economist, and his writings are always valuable and interesting. The present volume is composed of three discussions of questions involved in the ownership, operation and proper regulation of municipal public service industries, written for different occasions, and now published with a full index to facilitate an examination of the elements of the subject and a study of it in its entirety. The problems are examined from the standpoints of taxpayers, users of the services, employees and investors, and a scheme is presented by which it is hoped that municipalities and private capital can come together on a fair, equitable and permanent basis to avoid the many difficulties and disagreements which now occur.

Trade Catalogues

Catalogue for 1899 and 1900. Published by the Gold Car Heating Company, New York. Cloth. 80 pages. Illustrated.

Catalogue. Published by Gates & Randolph, Chicago. 20 pages. Illustrated.

Feed Water Heaters and Steam Separators. Published by the Harrison Safety Boiler Works, of Philadelphia. 48 pages. Illustrated.

Catalogue. Published by the Bullock Electric Manufacturing Company, of Cincinnati, Ohio. 62 pages. Illustrated.

Street Railway Journal

VOL. XV. NEW YORK AND CHICAGO, SEPTEMBER, 1899. No. 9.

A CROSS COUNTRY ELECTRIC RAILWAY IN EASTERN MASSACHUSETTS

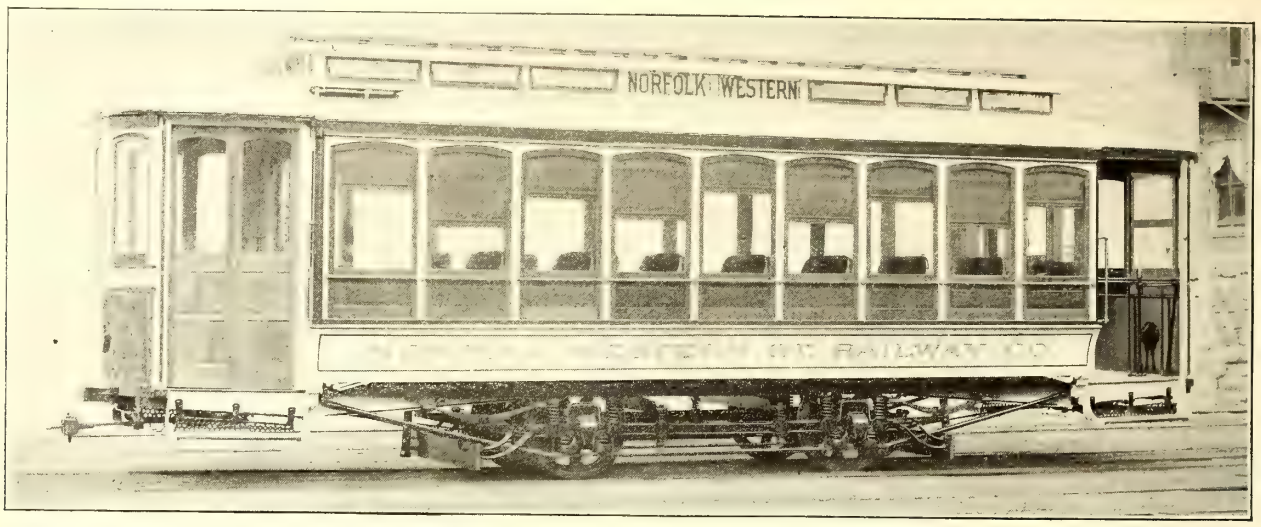
The remarkable electric railway system of Eastern Massachusetts, a system comprising nearly 1500 miles of track contained within but five counties, and paralleling and cross connecting with the closely-woven network of steam railroad lines contained in the same area—all giving transportation facilities to the people of this favored section unequaled in the world—has been developed in three different stages.

In the first stage, the half dozen independent horse railway properties in Boston and the immediate suburbs were reduced by consolidation to two, electricity was adopted, and, thus possessed of greater competitive power in the suburban transportation field, the lines of the metropolitan system were pushed into an outer fringe of suburbs, still, however, contained within a radius of about 10 miles of the central business district.

CAR HOUSE, TRANSFORMER STATION AND WAITING ROOM OF THE NORFOLK WESTERN STREET RAILWAY

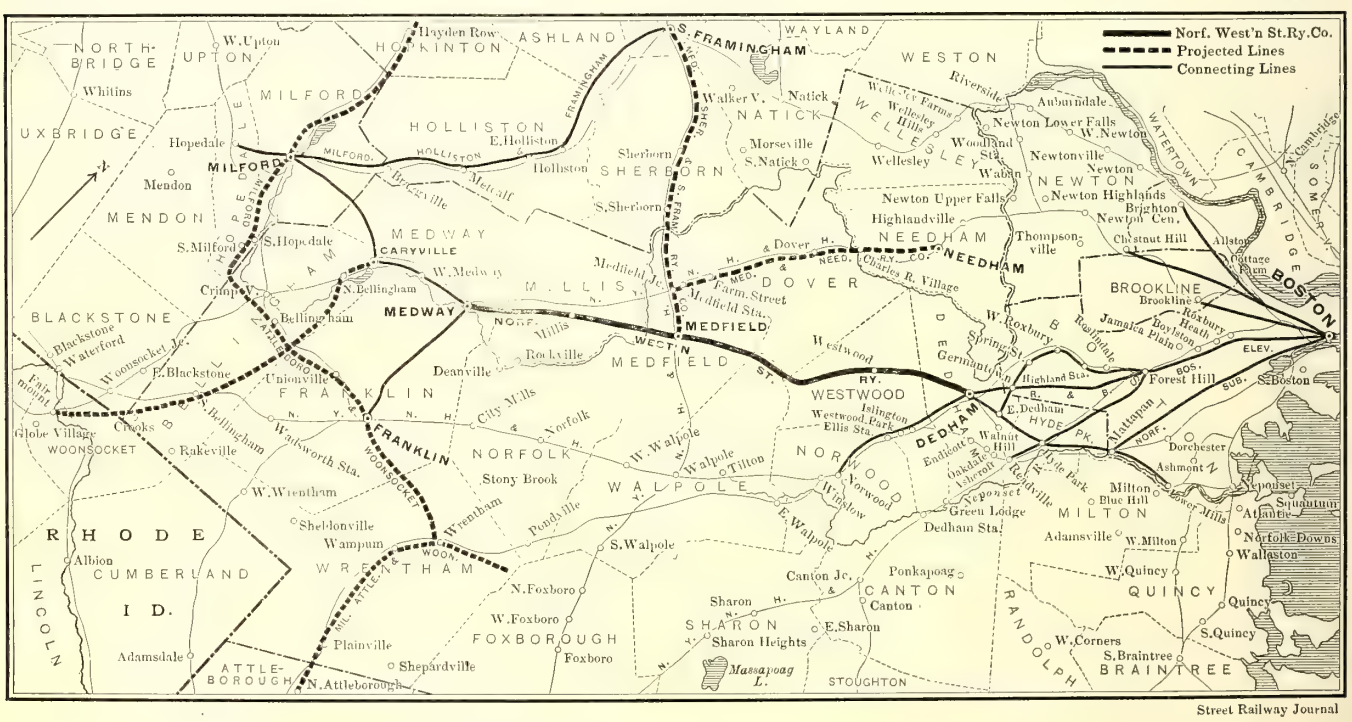
The mileage of this consolidated metropolitan system was then (1890) larger than that of any other street railway property in the world. The money requirements for reconstruction and electrical equipment were so heavy, the organization was so complex, and the engineering and operation problems were so absorbing that the management had little time or disposition to add to its burdens by reaching out still further into the surrounding country, although the beautiful clusters of cities and towns, north, west and south, must have offered great temptations, in spite of the more or less uncertainty in those days about the traffic-developing power of electric traction.

The second stage, therefore, came in the building by independent companies of a large number of "feeder lines" tributary to the metropolitan system, and laid out still on lines radiating from the city proper. These lines were generally profitable almost from the first, and later on became quite distinctly so, as a rule, though a rule not without exceptions. The increase of transportation facilities brought about a movement of the population from the city and the near-by suburbs to the remoter ones, buildings went up rapidly, and while there was little direct "booming" of real estate, such as is found in newer and less conservative districts, there was a substantial and very heavy growth of population and increase of values, which had a reflex action upon the prosperity of the electric railways in the new territory.



Now, Boston is by no means the only business and manufacturing city in Eastern Massachusetts. Lynn, Lowell and Lawrence on the north, Worcester on the west and Brockton on the south, are all centers of an independent money-making activity, each with its own suburbs and townships more or less dependent upon it for trading purposes. It came about naturally, therefore, that these cities also should first have their own local systems, and should then follow the example of the Boston lines in gradually extending to adjoining townships. The result was, therefore, a series of little independent street railway networks separated from the metropolitan system, but awaiting only opportunity, courage and capital to become firmly welded thereto.

Thus has come the third stage in Massachusetts' electric railroading, by which "cross country" connecting lines are building everywhere throughout this rich territory. It is now a joining together of small towns and of suburbs each with the other, the metropolis itself being only indis-



tinctly visible through many transfer connections. Pleasure riding has become a science in Eastern Massachusetts, and guide books, time tables, posters and all the varied literature which we have been accustomed to think of as belonging solely to railroad passenger departments have been drawn into service to increase the movement of the population from one point to another. Parks have been developed to some extent, although the magnificent park and boulevard system which the State of Massachusetts has so wisely provided in this beautiful district, furnishes in itself almost sufficient attractions to the people for pleasure riding.

Nevertheless, these cross country lines must, as a rule, look to the future rather than the present for any large profits, and it is probable that their destiny lies largely in consolidation, rather than in independent existence. This consolidation has, in fact, already commenced, for during the past few months there have been brought together under one control more than thirty street railway properties, built in the first and second stages of development, and forming the "Massachusetts Electric Companies," so called. As the earning power of the cross country lines is ascertained and established, it is probable that further absorptions may take place.

One of the most prominent centers of electric railway activity in the entire district of Eastern Massachusetts is the quiet town of Dedham, lying 10 miles to the south of Boston, and forming the terminus of the "Dedham Circuit Line" of the New York, New Haven & Hartford Railroad, upon which an excellent train service is given. Dedham is connected with Boston through Forest Hills and with the coast line by electric railway lines which have a large patronage. Within the last two years a line has also been built to Islington and Norwood on the south, and in May, 1899, the Norfolk Western Street Railway Company, the subject of this present article, opened its line from Dedham through Westwood to Medfield. Construction is now going on from Medfield through Millis to Medway (see map herewith), and these lines will eventually connect with the Milford, Attleborough & Woonsocket Street Rail-

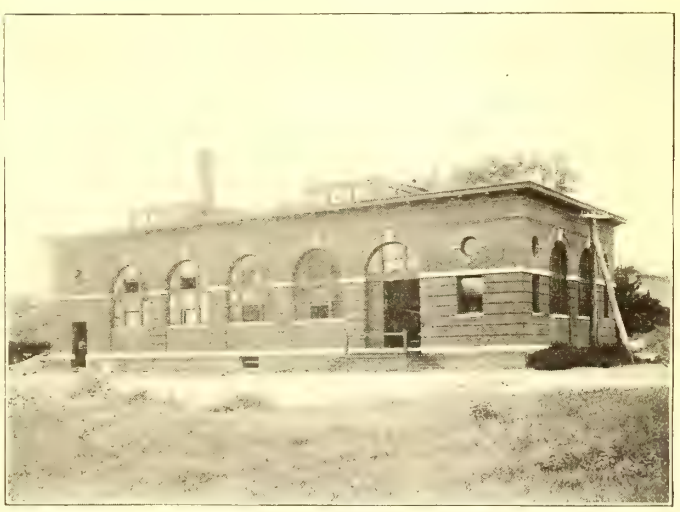
CONVERTIBLE CAR, NORFOLK WESTERN STREET RAILWAY COMPANY

MAP OF NORFOLK WESTERN RAILWAY AND ALLIED LINES

way, to be built by the same parties in interest. From Medfield also will be built the Medfield, Sherborn & South Framingham Street Railway and the Medfield & Needham Railway, both owned also by parties interested in the Norfolk Western Street Railway Company. At Milford and Dedham the Norfolk Western system joins the line of the Massachusetts Electric Companies, thereby obtaining Boston connections.

By the last Massachusetts census, in 1895, the population of Dedham was 7211, of the town of Dover 668, of Westwood 1800, of Medfield 2872, a total population

TRANSFORMER STATION AT WESTWOOD



DEDHAM TERMINUS

reached by the portion of the line so far built, of 12,551. Adding to this population that of Millis and Medway we obtain a total population for the present and projected lines of the Norfolk Western system alone of about 34,551. The fare from Dedham to Westwood is 5 cents, from Dedham

MEDFIELD TERMINUS

POWER STATION AT MEDFIELD

to Medfield 10 cents, and when the extension to Medway is completed an additional 5 cents will be charged. The distance from Medfield to Boston by the combined electric roads will be 19 miles and the fare 20 cents, as against the steam railroad distance of 24 miles with 56-cent fare, while from Medway, which is on another branch of the New Haven system, the distance from Boston is 26 miles and 61 cents fare is charged, while by the electric road the distance is 24 miles and a 25-cent fare will be charged.

The country through which the line passes is distinctly a farming region except that Dedham has a large suburban residential population. The country is exceedingly beautiful in summer, the line passing through pleasant groves and long, quiet country roads to its termini at Dedham and Medfield Squares.

It is obvious that in building cross country lines of this character, where cars must be run at comparatively infrequent schedules, at least until sufficient traffic is developed to warrant closer ones, the investment account should be kept as small as possible. The distribution system particularly might easily be a heavy burden to carry if ordinary 500-volt direct current distribution were adopted, or if power stations were placed ill advisedly. On the other hand, speed is a necessity in this cross country work, and great care must be taken with the roadbed and equipment to permit high speeds to be obtained.

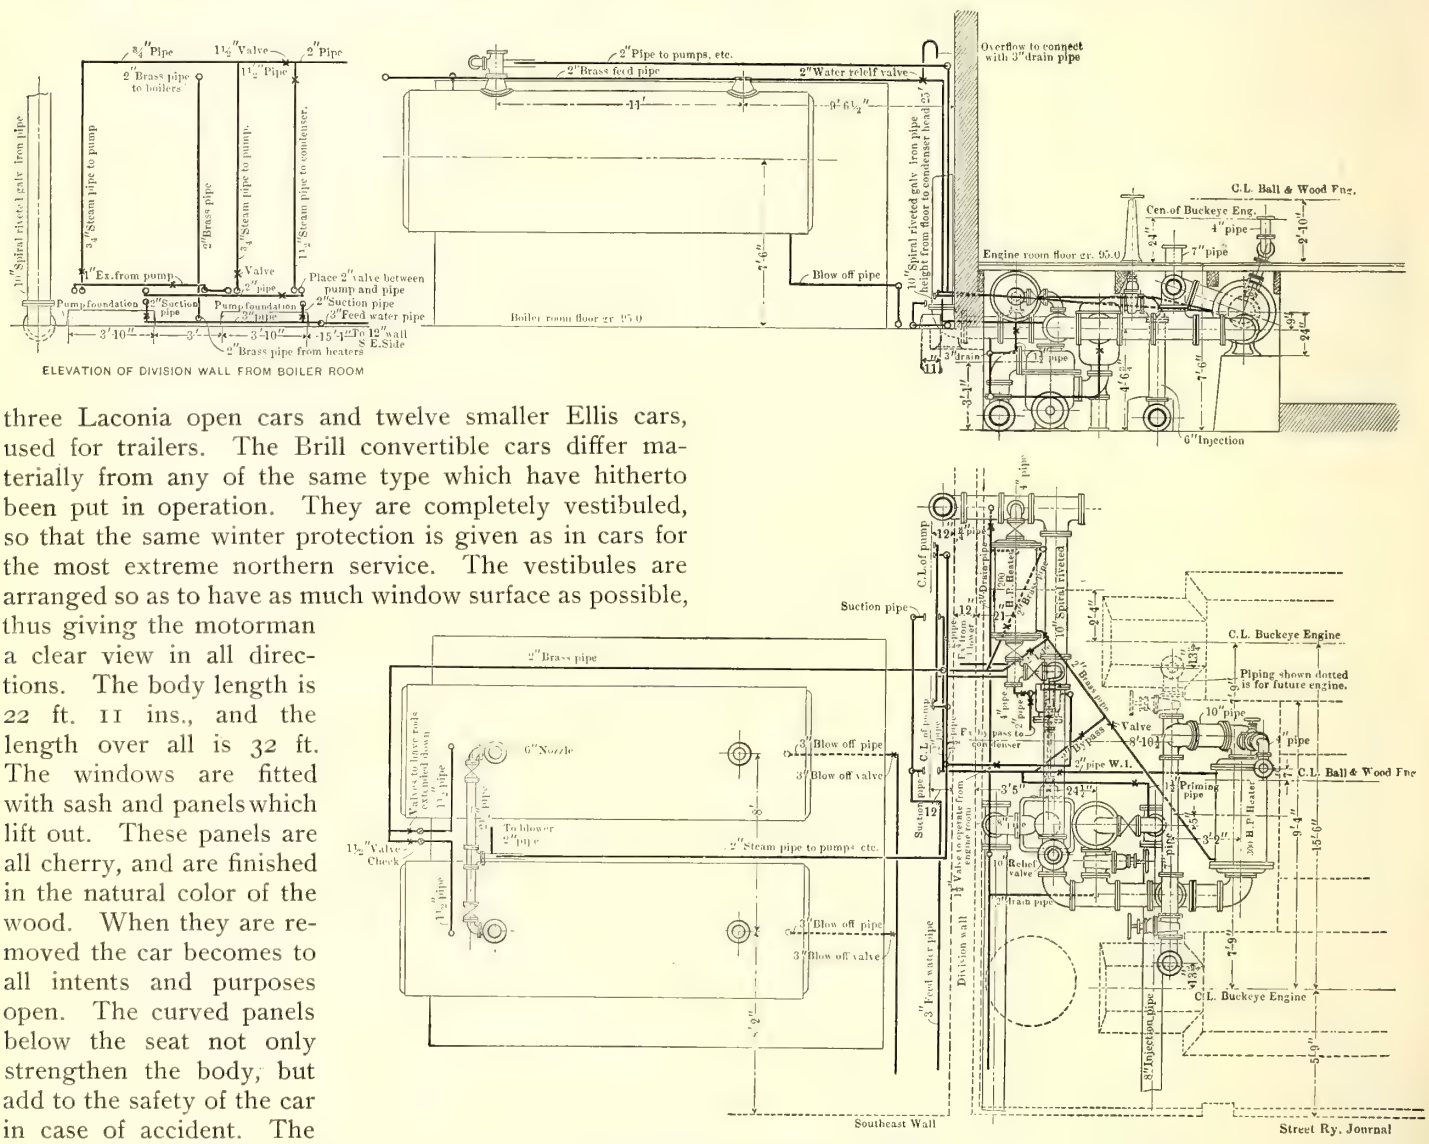
The Norfolk Western Street Railway Company has built its line thoroughly and well, and no money has been spared to give the property the best chance of success from an engineering standpoint. As a consequence, it is in many respects a model cross country road, the characteristics of which may well be carefully studied by those who are proposing to do work of a similar character.

The line as so far constructed from Dedham to Medfield is 9 miles in length. Its maximum grade is 5 per cent and its curves are from 125 ft. to 145 ft. radius. The track is placed chiefly on the side of the road, with bracket pole construction, and there are a number of crossings from

one side of the road to the other, which, joined with the general crookedness of the country road over which it runs, makes the track itself follow anything but a straight line. In Dedham and Medfield 90-lb. girder rails are used, and between the cities 60-lb. T rails. The ties are oak, and are placed 18 ins. apart between centers, and the rails are laid with broken joints, each joint laid on two ties. The sub-structure is rock ballast and gravel, and is firmly settled and placed so that the track is quite smooth and easy running. The rails are double bonded and cross bonded every 100 ft. with Chicago bonds. The poles are of hard pine and chestnut, and iron brackets are used.

The rolling stock consists of four Brill convertible cars, three Laconia open cars and twelve smaller Ellis cars, used for trailers. The Brill convertible cars differ materially from any of the same type which have hitherto been put in operation. They are completely vestibuled, so that the same winter protection is given as in cars for the most extreme northern service. The vestibules are arranged so as to have as much window surface as possible, thus giving the motorman a clear view in all directions. The body length is 22 ft. 11 ins., and the length over all is 32 ft. The windows are fitted with sash and panels which lift out. These panels are all cherry, and are finished in the natural color of the wood. When they are removed the car becomes to all intents and purposes open. The curved panels below the seat not only strengthen the body, but add to the safety of the car in case of accident. The drop platform and a step with 13-in. rise bring the tread of the step within $15\frac{7}{8}$ ins. of the head of the rail.

Inside, the car is 8 ft. 2 ins. in the clear. On each side of the center aisle are seven seats, with reversible backs, and at the ends are four stationary seats. The total seating capacity of the car is thus thirty-two. The seats are upholstered in red plush. The interior finish over the windows is of cherry and the head lining is of maple veneer highly decorated.



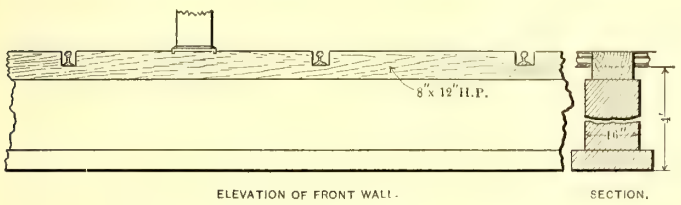
A Gold electric heater is placed under each seat. The car is lighted with nine lights within, and one for the headlight. New Haven registers are used.

The cars are mounted on heavy No. 21-E Brill trucks, with an 8-ft. wheel base. The wheels are 33 ins. in diameter and the gage 4 ft. $8\frac{1}{2}$ ins. "Composite" brake shoes are used, manufactured by the Barbour-Stockwell Company. The electrical equipment consists of two G. E. 1000 motors, with series multiple controllers, etc. Sterling brakes are used.

The company also owns a Wason snow plow and a Trenton tower wagon, and has fitted up a short car as a watering car, which will run over the road regularly.

The three-phase system of electrical distribution has been adopted for this road after the most careful consideration on the part of the company's engineers, Hodges & Harrington. The power station is located at a point in Medfield about 2 miles southwest of the present Medfield terminus of the constructed road, and is thus in position to feed the line both ways, towards Dedham and towards Milford. A 60-cycle 2080-volt current is generated at this station, at which pressure it passes over the line to the transformer station at Westwood, where step-down transformers deliver it at 340 volts alternating to rotary converters, from which a 550-volt direct current passes to the trolley wire. By means of the high voltage line transmission the three-phase feeders from Medfield to Westwood consist of but three 00 wires and a single direct-current feeder runs $1\frac{1}{2}$ miles each way from the Westwood transformer station, and is 0000 in size. A 00 trolley wire is used. The fluctuations on the line, which would naturally be somewhat heavy owing to the small number of cars used, are reduced in amount by the use of a storage battery consisting of 264 cells of the chloride type, made by the Electric Storage Battery Company, of Philadelphia.

The power station at Medfield Junction is a handsome,

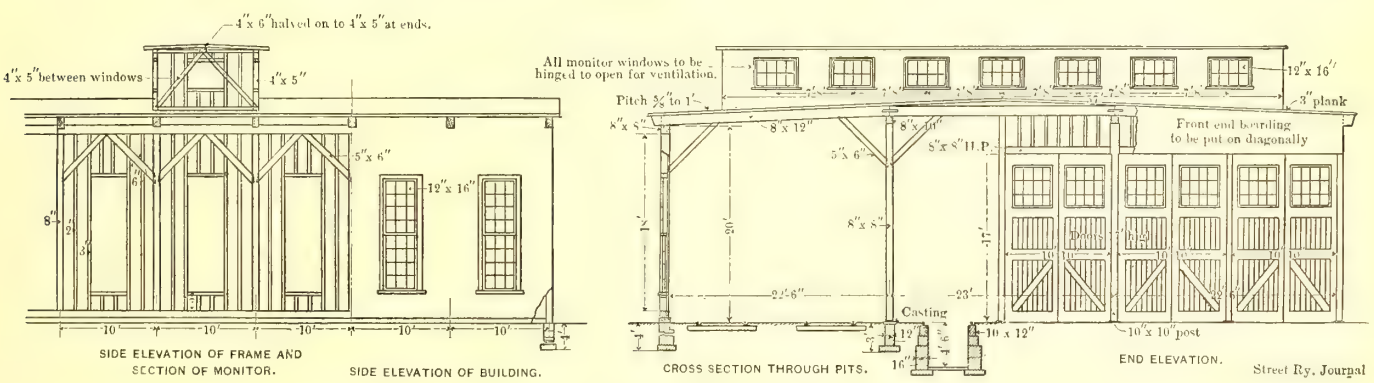


PLAN AND ELEVATION OF POWER STATION AT MEDFIELD

ELEVATION OF DIVISION WALL FROM BOILER ROOM

well-built brick and granite structure, 85 ft. long x 40 ft. wide, containing the engine room, 48 ft. x 40 ft., and the boiler room, 37 ft. x 40 ft. A tar and gravel roofing covers the station. It was built in 1898-9 by the Jarvis Engineering Company, Hodges & Harrington being the consulting engineers and Robert Coit, the architect. In the engine room is a 250-h.p. Ball & Wood engine and two 140-h.p. Buckeye engines, belted to four General Electric three-phase generators by 16-in. belts.

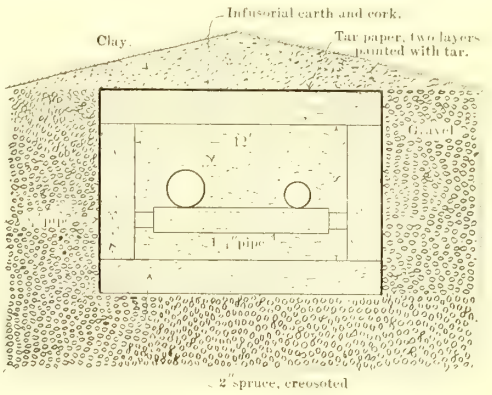
The boilers are three in number and are of the tubular pattern, and are of 125 h.p. size. The station has two American feed-water heaters, two separators, an 8-in. x 22-in. Dean condenser and two 6-in. x 3¾-in. x 7-in. Dean pumps. Coal is obtained by a side track from the New



SECTION OF FLOORING IN CAR HOUSE

Haven Railroad. Ground connection is made by a copper plate sunk in the ground and surrounded by charcoal.

At Westwood are found three exceedingly neat and attractive buildings, one a car house, the second the transformer and storage battery station, and the third a passenger waiting room.



The car house is of wood, 130 ft. x 69 ft. in size, and has a capacity of thirty-two cars. To the central portion are appended two wings, one the superintendent's office, the other the motormen's and conductors' lounging room. In the latter each man has a separate locker for his extra clothing, etc., and there are toilet rooms fitted with every convenience. Entrance to the car house is made by switches running in generous curves both ways from the main line, which latter passes the waiting room, which is immediately in front of the car house. No transfer table is used in the car house, but cars are run upon any one of the car tracks desired, by means of switches. The three central tracks have deep pits connected with each other below, so that passage can be had from one to the other,

WESTWOOD CAR HOUSE

and another pit running at right angles permits motors to be brought from the pit to the surface on an inclined plane overhead. In the car house are cranes and hydraulic apparatus of sufficient strength to make it possible to lift a car while trucks are moved and replaced or motors attached. In the pits are steam pipes connected with a boiler in the transformer station, by means of which the barn will be kept warm and the cars dried out in winter. At the rear of the car house are the repair shops, consisting of a carpenter and machine shop, in which are an 8-ft. lathe, an upright drill, a band saw, a hack saw and a grindstone, all run by a 5-h.p. motor. Three men are employed here.

The transformer and storage battery station is built of field stone, and presents a novel and attractive appearance. It is divided into three sections, of which the one in front nearest the road is for the batteries, the central one for the

CONDUIT FOR STEAM PIPES FOR HEATING WESTWOOD CAR HOUSE

transformers, while the rear room contains a 100-h.p. boiler and pump, which are used for heating and pumping. Back of the group of buildings on the hillside is a standpipe, and somewhat forward of this is a large well sunk to a depth of 30 ft. and usually full of water. The standpipe is kept filled with water for fire and car-washing purposes, and when emptied to a certain point the boiler is fired and the water pumped from the well to fill the standpipe.

In the transformer room are six step-down transformers, built by the General Electric Company, and of its type H, each having a capacity of 30,000 volts and adapted for a 60-cycle transmission. On a line at right angles with these transformers and with the station switchboard are two rotary converters of the General Electric type, 4-75-1800, and of a capacity on the direct current side of 136 amps. at 550 volts. On the three-phase side the voltage is 340, delivered from the step-down transformers. The speed of the converters is 1800. The switchboard is of marble, and contains two Weston continuous current ammeters, two Thomson alternating current ammeters, a Weston ammeter for the battery circuit, and necessary switches, automatic cutouts, battery circuit breakers, etc.

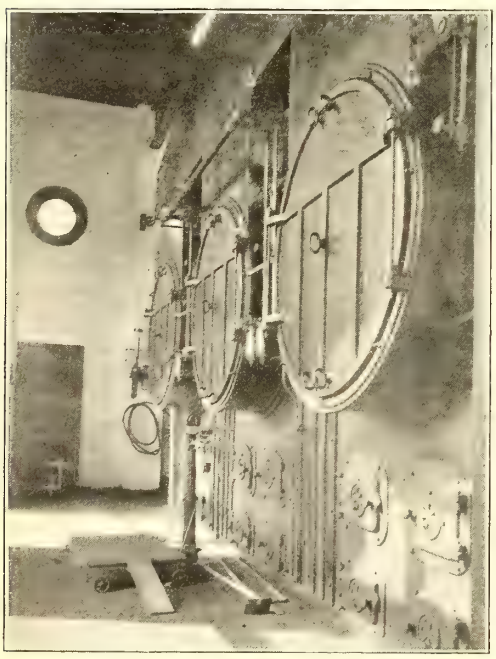
The waiting room at Westwood is also built of field stone, and, in addition to accommodations for passengers, contains a cigar, confectionery and news stand and other conveniences of a similar character. It has a large open fire-place, which will probably come into excellent use during the winter months.

On the front of the car house are large balls of incan-

descent lamps, which are illuminated at night and add to the attractiveness of the spot. There is also a clock similarly illuminated, so that the time can be seen day or night. The company possesses a car which it has specially fitted up for excursion travel with a large number of incandescent lamps, and at present it is sending this car over the line each night and into the terminal towns as a kind of advertisement and an attraction to travel. The result has been that the cars have been quite fully loaded in the evening hours, although ordinarily little traffic would be obtained at such hours.

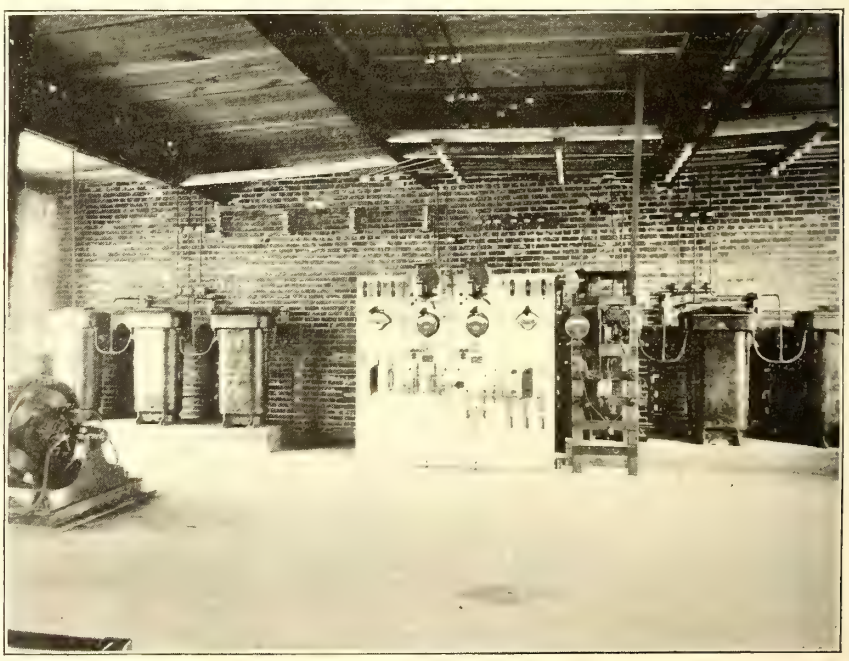
The company employs eight motormen, to whom it pays $2 a day for a ten-hour service.

The officers of the company are as follows: president, J. F. Merrill; treasurer, James A. Fitton; superintendent and electrical engineer, Edward C. Spring. The chief engineer of the power station is A. E. Read. One of the parties largely interested in the system is John R. Graham, of Quincy, general manager of the Quincy division of the Massachusetts Electric Companies.



A Difficult Piece of Track Conversion

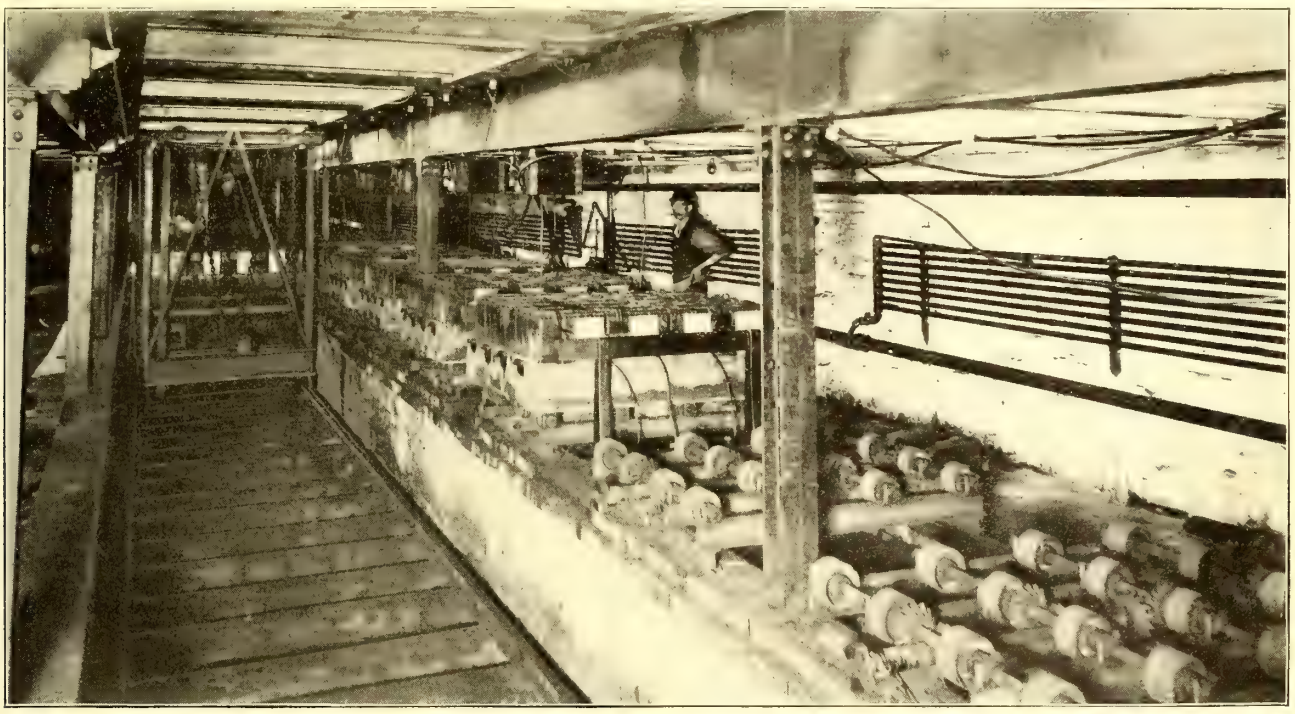
There is now in course of construction on a section of Broadway, New York city, an open conduit track, the work on which is about as difficult an undertaking of its kind, outside of switches and crossings, as can be imagined. The Metropolitan Street Railway Company has had in use for a year and a half on this section its standard underground trolley track with central conduit and slot carrying the Amsterdam Avenue cars. The Third Avenue Railway possesses a right of way through the same street on what is known as its Boulevard line. To operate the latter line electrically and by the independent power system of the latter company a separate pair of conductors in a separate conduit were needed, but the company was not allowed to lay another pair of tracks. The existing conduit is therefore being pushed over to one side to give room for the other conduit beside it between the track rails.



Difficulties are introduced by the fact that the track is being kept in service for the Amsterdam Avenue cars with a headway of about two minutes and the conductor rails must therefore be kept "live" throughout the progress of the work. The line runs all night, so that there is no opportunity to work while it is shut down. The change is being accomplished as follows: The pavement is first removed and the heavy concrete foundation and conduit wall is broken up and removed piece by piece from around the yokes and live conductor rails, the track being shored up meanwhile to carry the heavy double truck cars which constantly run over it. Temporary wooden yokes are then inserted to maintain the gage of the track rails, and the old yokes are loosened from them and pushed to one side, carrying with them the old slot rails, insulators and conductor rails. The conductor rails are then removed in single rail lengths, and the free ends are fitted with outwardly flaring slippers to prevent the shoes on the plows of the cars from being carried away, the cars being allowed to drift through this open section. The old yokes are promptly removed and replaced by new ones fitted with apertures for the two conduits symmetrically placed between the track rails. The track as completed has only one pair of track rails and two slots.

STORAGE BATTERY ROOM IN TRANSFORMER STATION

BOILER ROOM AT MEDFIELD

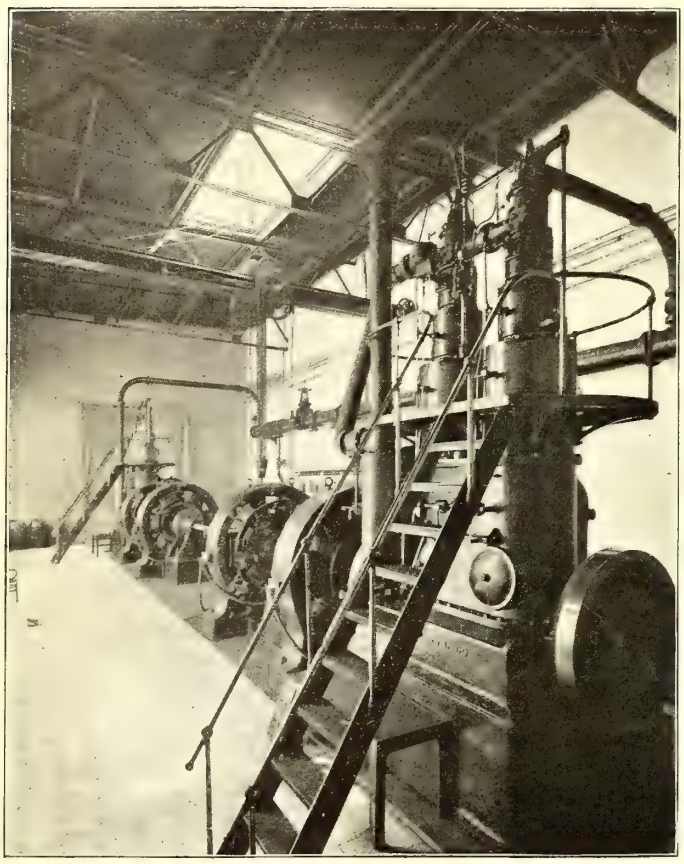


TRANSFORMER ROOM

The Englewood & Chicago Storage Battery Line

The storage battery cars on the line of the Chicago Electric Traction Company, formerly known as the Englewood & Chicago Street Railway Company, have now been running a little more than two years, and are said by the management to be handling the traffic in a satisfactory manner. It is not claimed, however, that cars can be operated more cheaply by the storage battery than by the overhead trolley system, but that for suburban lines of this character, or in cities where the overhead trolley is not allowed, the storage battery provides a very efficient and acceptable method of electric traction. The cost per car mile for operating the system in 1898 was 8.7 cents, and during the month of August it was as low as 7.2 cents. This year it is a little higher owing to track repairs which were not required during the first two years of service.

The original equipment of the line embraced 24 miles. The main system extends in a southwesterly direction from Sixty-third Street and South Park Avenue to the village of Blue Island, with a branch running to Morgan Park. On this branch is a 9 per cent grade, up which the cars are assisted by a balance weight system designed by M. H. Bronsdon, of Providence, R. I. The system has recently been extended as a single track line a distance of 5 miles to Harvey, and the cars are now running through to the latter place, where a small power station has been erected. The company has in regular operation twenty-five cars, for which forty batteries are provided. The latter are of the Electric Storage Company's type, manufactured in Philadelphia, and what is known as the Manchester plates are employed.

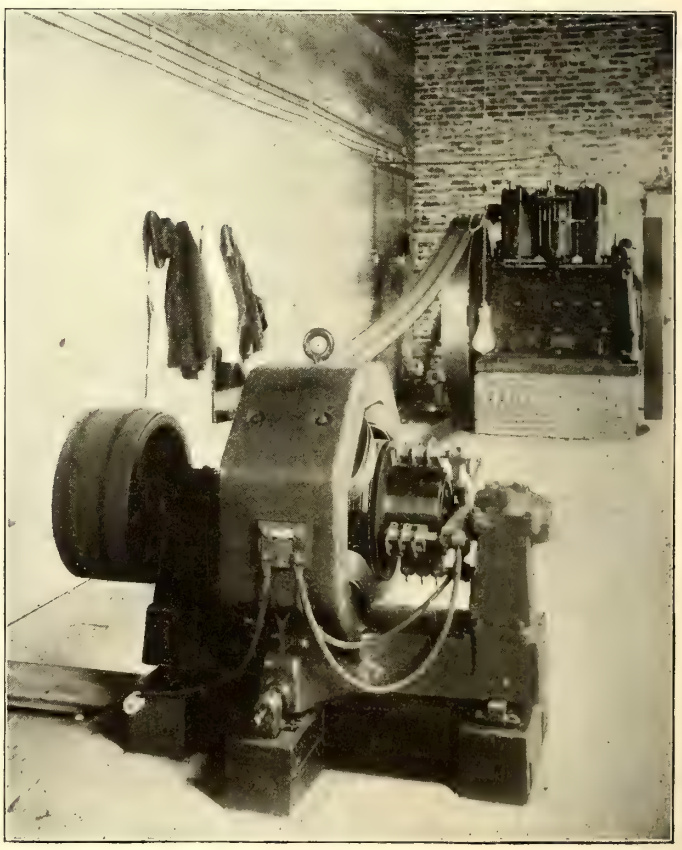


Each battery is composed of 72 cells, arranged in a tray, by means of which it is shifted about or removed or replaced in the car. The weight of each battery, including the tray, is about three tons. The cars are mounted on Dupont trucks. The battery is carried in the middle of the truck between the axles, and is removed and replaced from beneath. A 525-lb. wheel and a 4-in. steel axle are employed. Each car is equipped with a 50 h.p. Walker motor, which is mounted outside the axle, and during the hours of excessive traffic each motor car hauls a trail car. The distance traveled by one charge of battery is 11 miles. A much longer distance can be run when necessary, but about this distance is regarded as the most economical. Each cell of the battery is charged to an e.m.f. of 2.18 volts. In the trip of 11 miles this is reduced to two volts, and it is seldom that the batteries are reduced below this rate. The life of the positive plates of the battery is sufficient for a distance of 23,000 miles, and the negative plates for about twice that mileage, or the negative plates will usually outlast two sets of positive plates. The plates are run until the surface is too much reduced by the dropping out of the active material from the grids. Worn plates are not repaired, but the waste material, in the form of fine powder, is sold to the junk dealers. In service the plates do not buckle, but it is found to be of advantage to thoroughly wash and clean them after making about 4,000 miles. The electrolyte is composed of distilled water with chemically pure sulphuric acid at a density of 12.25. This is found to be reduced by 15 degs. on account of spilling and evaporation in about three weeks, when the cells of each battery are replenished and the fluid is brought up to the standard.

STORAGE BATTERY PIT AND SHIFTING CAR

The main power station is located at Eighty-eighth Street and Vincennes Road, about 5½ miles from the northern terminal of the line, and the most interesting feature of the station is the arrangement and location of the batteries and the method employed for shifting and replacing. The battery pits occupy two long rooms in the basement, as illustrated on this page. These pits extend under the car house in a line at right angles to the car tracks and the street tracks which pass in under an alcove extending in front of the station. Each battery pit is provided with a sunken way, in which is a track over which a shifting car operates. There are two of these cars, one in each pit. Each tray of battery is located on a nest of rollers, as shown in the illustration, which are connected by a system of shafting and beveled gear, the main shaft terminating in a clutch at right angles to the line of the tracks. The shifting car is constructed of a steel framework, is equipped with five motors and is controlled by levers arranged at the middle section of the car, as shown. At each end of the car is a platform equipped with rollers, the same as those for supporting the batteries in position. This platform is

fitted with an elevating apparatus, by means of which the exhausted battery is removed and a fresh battery substituted. For loading the battery on the platform, the car is run into position, when the shaft on the car platform is automatically coupled to that supporting the battery; the shaft is then revolved by the car motor and the battery rolls forward on to the car platform. The car is then run



MAIN POWER STATION

down the line directly under the shifting pit, when the vacant platform is raised and the exhausted battery lowered from the car. The battery or shifting car is then moved forward, bringing the fresh battery directly under the shifting pit, when this in turn is elevated and automatically hooked into the truck, while at the same time the connections are automatically made by contact springs, located on the sides of the tray. The platform is then lowered and the replenished car proceeds on its course. An expert in handling the shifting car has been able to remove and replace a battery in 28 seconds, ordinarily it requires about one minute and a half. The exhausted battery is returned and shifted to the charging stand in the same manner as described for loading.

All the appliances for charging and shifting the batteries have been designed on very ingenious and economic lines, and it is hard to conceive how they can well be improved upon, as no hand labor whatever is required in shifting or in making connections for charging. In charging the batteries a current of only 160-volt pressure is first employed. Afterwards this is raised in stages to 170 volts and finally to 180 volts. The motors are wound for operating normally under 135 volts pressure, but have never been injured by the ordinary voltage delivered from the battery. During more than two years of service no repairs whatever have been required on the motors. The manager would prefer to have two motors to the car, especially for winter travel, and it is the intention of the company to provide two motors on all new cars. As it is, only a little difficulty is experienced in keeping the cars operating during snowy weather. The snow plows and sweepers are equipped with three sets of batteries, and are as efficient as the trolley sweepers in keeping the tracks clear from snow and mud. The power equipment of the main station consists of two 250 h.p. Willans' central valve high speed engines and four 250 kw. Walker generators. The engines are vertical, triple expansion, condensing and run at 380 r.p.m. One is placed at each end of the engine room, and they are connected by a system of hollow shafting and clutches so that either one of the engines can be made to operate either or all of the four direct coupled generators, one engine and two generators being regarded as a unit, however. In charging the batteries three circuits are employed, as above described, so that one generator may be run at 160, the second at 170 and the third at 180 volts. When only two generators are run the voltage is 166 and 178. During the time of light loads but one engine is run, but for heavy traffic both are employed.

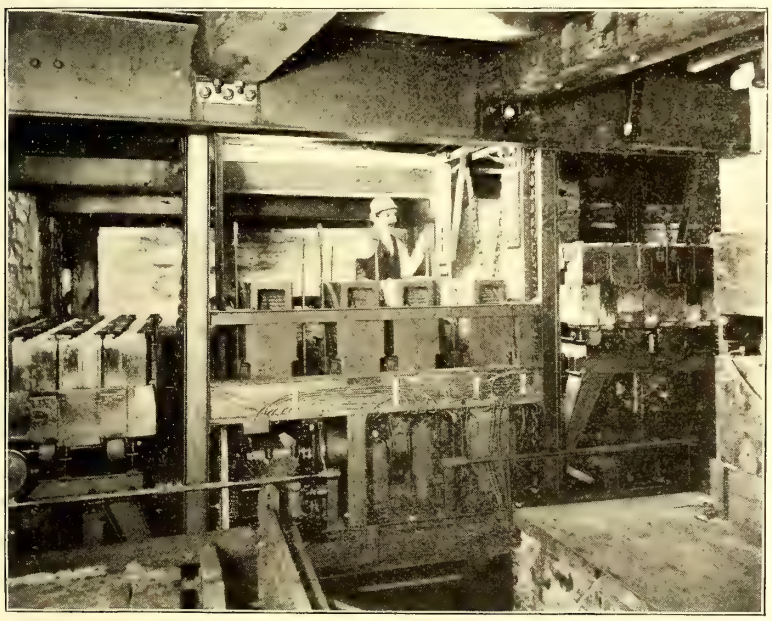
These engines were made by the M. C. Bullock Manufacturing Company, of Chicago, and are of the same type that this firm had running on exhibition at the World's Fair in 1893. They have been in constant service in this storage battery plant since it was installed in 1896, and are still working without any apparent depreciation. Each engine, as illustrated, is really a double vertical engine, and each half consists of three tandem cylinders, or is a tandem triple expansion single action engine, with central simple valve gear, with a fourth cylinder at the base, which acts as an air cushion. An important and particular feature of

HARVEY SUB-STATION

this type of engine is the drainage arrangement, which is accomplished by having the pistons dished downward in the center, while the hollow piston rod has a ring of ports flush with the surface of the piston, being in the best possible place for drainage. This feature is claimed to make a saving of at least 15 per cent in the steam consumption, as there is no water left in the cylinder to rob the incoming

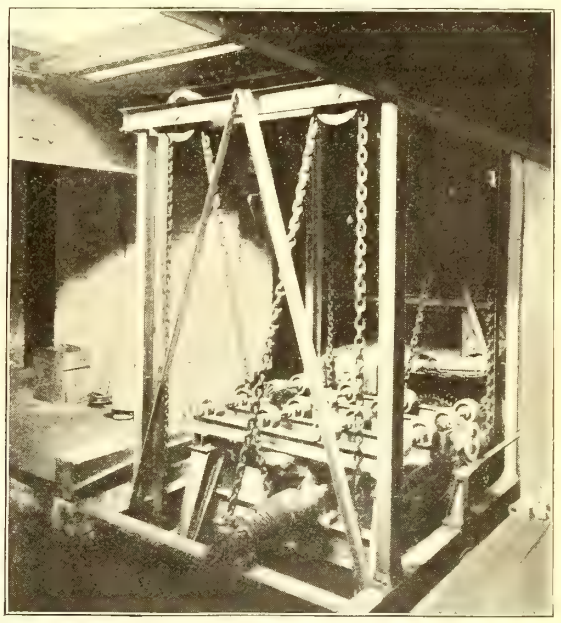
steam of its heat during the period of admission. Paradoxical as it may seem, the piston speed, 500 ft. per minute, owing to the short stroke, only 8 ins., is slower than in so-called slow running engine. In these engines the diameter of the three cylinders is as follows: Low pressure, 23⅝ ins.; intermediate, 14 15-16 ins.; high pressure, 10¼ ins. The engines run entirely noiseless, and the governing features are unusually sensitive and efficient. Among the claims for this type of machine are durability, economy and safety.

The boiler equipment consists of three 200-h.p. Heine boilers, provided with Roney mechanical stokers. Jet condensers are employed and there is a cooling tower, installed by the H. R. Worthington Company, which consists of a steel tank, 30 ft. high and 12 ft. in diameter. This is partly filled with vitrified sewer pipe placed on end so that the water when pumped to the top of the tower trickles over the pipes to the tank below. The cooling blast is provided by a large fan, operated by an electric motor, which serves to cool the water that it may be used over and over again for condensing purposes.



The new power station at Harvey is equipped with a 50-h.p. Nash triple cylinder gasoline engine, manufactured by the National Meter Company, of New York, run at 250 r.p.m. This is belted direct to a 40-kw. Eddy generator, manufactured by the Eddy Manufacturing Company, Windsor, Conn. This generator is operated in multiple with a stationary storage battery in the station so arranged that when the current is not being delivered to the car batteries it is charging the stationary battery. This battery consists of 95 cells of 320 amp. hours' capacity. This station is provided with two extra car batteries, the same as those described above, and which are charged in connection with the stationary battery. The arrangement is such that a steady load is provided for the engine and the car batteries are charged without an undue expenditure of power. The battery shifting device provided for the Harvey station differs somewhat from that described for the main station, as the trays are mounted on trucks and are rolled by hand power by means of a windlass under the elevating platform, which is raised and lowered by means of a stationary motor. The Harvey power station is a one story plain brick building, 30 ft. x 70 ft., and is divided lengthways into two sections. In one is located the track and pit on which the car is run for battery shifting. The other section houses the power equipment.

In connection with the operation of the line, a funeral car is operated when chartered, which serves to carry the attendance at funerals for the different cemeteries that are located along the line. This car is named Virginia, and is handsomely upholstered; in fact, it is finished very much like the private cars on other lines. End doors through the front vestibule provide for loading and unloading the box containing the body.



The system is now operated under the management of E. R. Gilbert, with A. E. Davis as superintendent.

Electric Road Between Haarlem and Zandvoort

During the first days of July the electric road between Haarlem and Zandvoort, the first of its kind in Holland, was put into operation. This occurrence has a particular significance, as the Netherlands, with their vast commercial interests, have heretofore arrayed themselves against the introduction of electric roads, and up to this time the short accumulator road, Haag-Scheveningen, operated in summer alone, was the only electric road in existence.

BATTERY SHIFTING CAR

END OF SHIFTING CAR

The projectors and owners of the new road are the Eerste Nederlandsche Trammaatschappij, of Amsterdam, the capital of which is 1,000,000 fl. The line was built and equipped by the Siemens-Halske Company. The generating station contains three units of 170 h.p. each, consisting of vertical engines direct connected to the well-known interior pole machines of the Berlin firm. The line is 16 km. (10 miles) long, and has two tracks along nearly its entire length. It also serves for the transportation of freight. At present the rolling stock consists of twelve small and eight large motor cars, nine trailers and four freight cars.

Card Catalogue of Employees.

The Milwaukee Electric Railway & Light Company uses the card catalogue system for keeping track of all employees, each being given a card on which is contained the history of his connection with the company from its beginning. This card shows the date of entering the pay-rolls, the occupation, the department, the salary per month, report number, the date of leaving service and the reasons therefor, the age, whether married or single, and the home address.

Practice in the Repair Shops of the North Chicago Street Railway Company

CUTTING GEARS AND PINIONS

All the gears and pinions employed on the lines of the North and West Chicago Street Railway Systems are cut and finished at the Limits Repair Shop, located at the corner of North Clark Street and Dewey Street. These shops are under the supervision of V. T. Lynch, who has designed most of the tools, or, in fact, all the tools described in this connection. For cutting the gears and pinions two old planers are employed. These have been fitted up with a cross-head, which carries the shafting and cutting tools, and have been provided with a belt shifting device and other attachments, as shown in Fig. 1. Two cutting tools are employed on each machine, one known as the stocking cutter, the other the finisher. These are attached to the ends of shafts which are driven from either side of the machine, so that the cutters are placed one in rear of the other, near the middle of the machine. The same general design is employed for both the pinion and gear cutting machines. For making the malleable iron gears blanks are employed, which are planed and mated, when after being bored out and turned down to the proper diameter, they are made ready for the gear cutting. Seven of the blanks are arranged on a shaft, as shown, with a templet or pattern wheel at the end. The bed plate carrying the gears is then started and the blanks, passing under the cutters, are each cut to the proper depth for a line of teeth. When finished the nest of gears is turned one notch by hand and fastened in place, when a second cut is made, and so on until finished. The pinions are cut in nests of six in the same manner as described for the gears, only one attendant being required for the two machines. In the operation a pump forces the lubricating mixture in quite a large stream to each of the cutters. The two machines have a capacity of eight pinions and two gears complete in ten hours. The blanks for the pinions are cut from hot rolled steel bars or shafts. These are drilled, turned to accurate size and cut off to a suitable length on a lathe, as shown in Fig. 2. The original bars are long enough for sixteen pinion blanks. For drilling the holes in the shaft two operations are required. A twist drill $1\frac{1}{8}$ ins. in diameter is first employed, and this is followed by a second about $2\frac{1}{4}$ ins. in diameter, and when sufficient depth is drilled, a section forming a single blank is cut off on the lathe.

Fig. 3 illustrates a keyway cutting device for cutting the keyway in the gears. This is a home-made machine, the frame work being constructed of two steel flat bars, the same as employed for grip slides on the grip cars. The gear is placed at one end of the machine, as shown, where it is held in position when the shaft or bar carrying ten cutting knives, which are placed 4 ins. apart, is forced endwise through the bore of the gear. Each of these knives is of the full width of the keyway, and each in succession is set about 1-32 in. higher than the other, so that by one motion of the shaft through the bore, a complete keyway is finished. This shaft, carrying the cutters, is forced endwise by means of a screw, cut on its outer extremity, and which is actuated by a nut in the driving gear, the shaft having a travel of about 4 ft. This is actuated by a countershaft and small gear, which is driven by means of

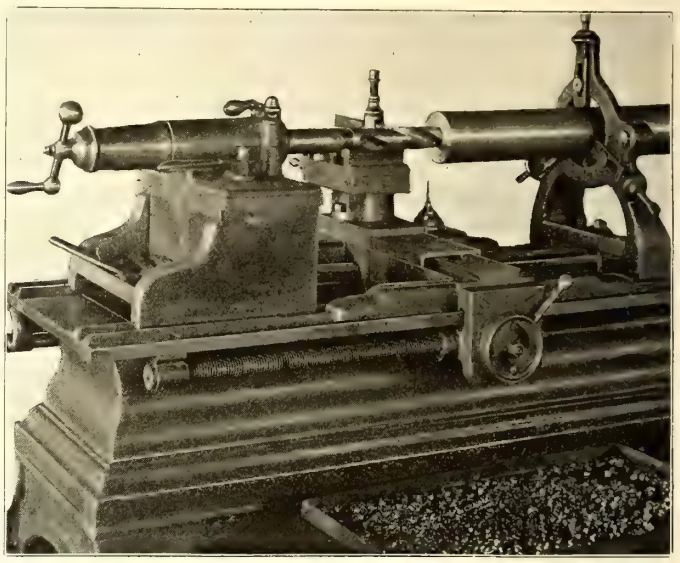


FIG. 2.—DRILLING AND CUTTING PINION BLANKS FROM HOT ROLLED BAR

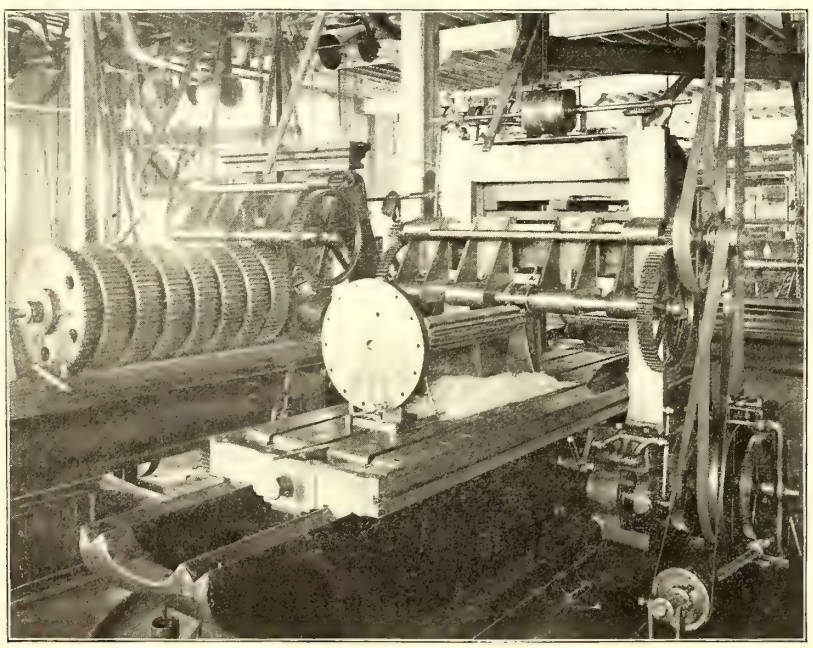

FIG. 1.—LATHE FOR CUTTING GEARS AND PINIONS

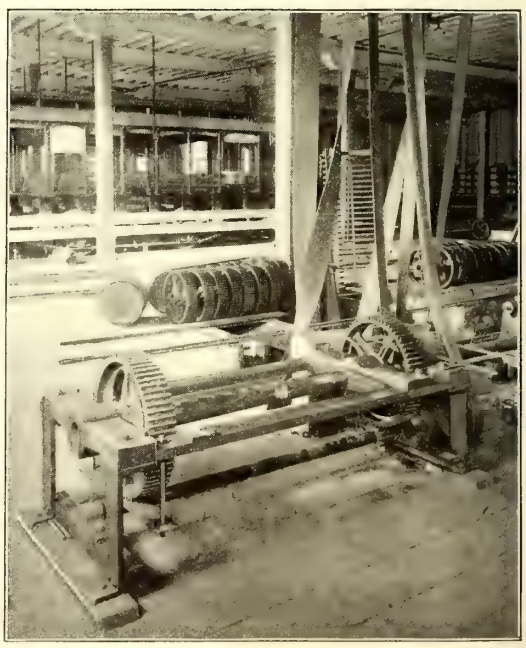

FIG. 3.—KEY WAY CUTTING DEVICE

belting from the overhead shafting. By the use of this machine it requires about a minute to cut a keyway in a gear, including the time consumed in putting the wheel in

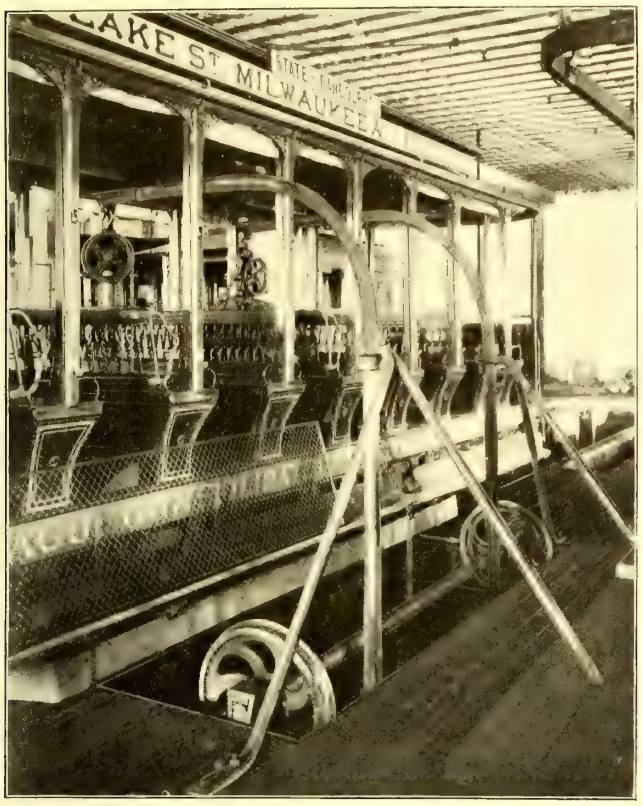

FIG. 4.—CRANE FOR LIFTING MOTORS FROM CAR ON TRANSFER TABLE

position and taking it out, and all the ways are cut to an exact size.

An electric motor drives the shafting for all the shop machinery, and there is an air compressor made over from one of the Connelly gas motors that were employed on this system some years since for driving the motor cars. These shifts the belt, starts or stops the compressor, at the same time cuts off or lets on the flow of water through the water jacket of the cylinder.

USE OF COPPER

Hard-drawn copper bars are employed in commutator construction. In practice it is found that the life of the commutator varies greatly, depending on the service. The cars on the lines of heavy traffic are the ones on which most of the repairs are necessary; the others seldom come in for repairs. It is the practice of these shops to return the copper wire employed in field coils to the manufacturers, after a coil has been damaged, to have it reinsulated,

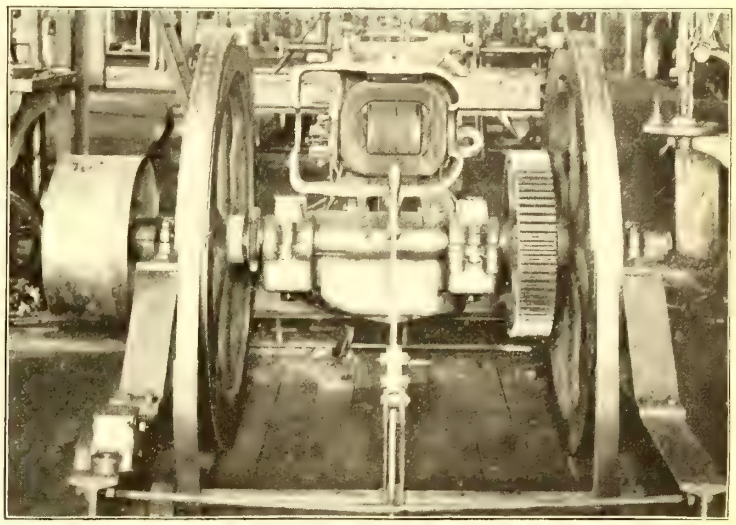

FIG. 5.—FRICTION BRAKE FOR TESTING ARMATURES

as it is found to result in quite a saving in the matter of motor repairs. Before shipping the coil away, however, the old insulation is all burned off.

MOTOR CRANES

In the repair department two stationary cranes of special design are employed for lifting motors or armatures out

FIG. 6.—FENDER FOR CABLE CARS, SAFETY GUARD SPRINGS BETWEEN CARS AND GUARD RAILS

provide the pressure for operating the power hammers in the blacksmith shop, will furnish the power for some pneumatic hoists which are about to be installed, and also blows the shop whistles. These compressors are provided with an automatic starting and stopping device, which was also designed by the superintendent of the shops. This device

from the open and sometimes from closed cars. These cranes consist of 3-in. bars of iron, bent as shown in Fig. 4, and braced in position at the end of the run of the transfer table. For removing any part, the car is placed upon the transfer table, when it is run in position to bring the ends of the cranes well within the car, as shown. Hand hoists

are then attached, the armature or frame is lifted to a suitable height, the car is moved away from the crane and the part which has been lifted from the car is lowered and shifted about the shop on trucks.

ARMATURE TESTING DEVICE

In Fig. 5 are shown the method and appliances for testing armatures. The motor case is mounted in brackets when the armature is put in place and current applied. By means of a gear wheel on the shaft, power is communicated to the two 4-ft. fly wheels, about each of which is a band brake, which is operated by means of a lever shown between the wheels. By means of the brake any degree of power within the capacity of the motor is obtained, and when the consumption of current reaches a certain amount, as indicated by the meters, the test is suspended. In addition to testing, this machine is sometimes employed as a motor for driving the shop shafting. For this purpose a belt pulley is attached to the end of the axle, so that the power is readily transmitted by belt to the shafting. This is used in case the motor which drives the tools of the repair shop should be out of order or undergoing repairs.

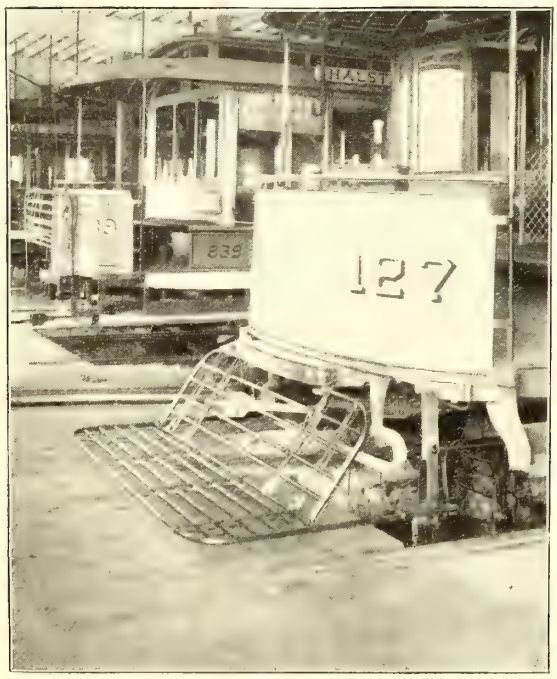

FIG. 7.—FENDER FOR ELECTRIC CARS

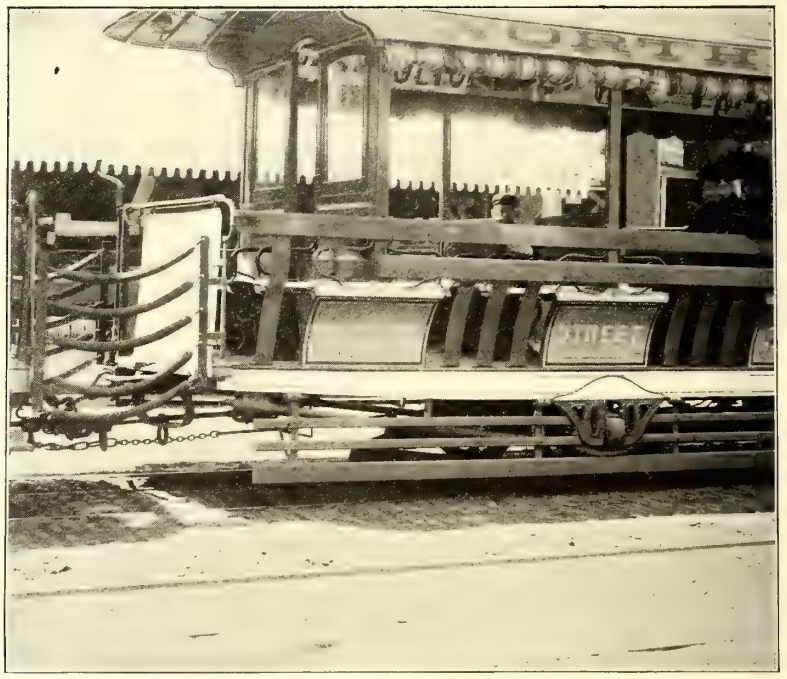

FIG. 8.—SAFETY DEVICES FOR TRAIL CARS

FENDERS AND OTHER SAFETY DEVICES

All of the cars, both electric and cable, on the North and West Chicago systems have recently been equipped with fenders to comply with the city ordinance to that effect. The fenders are all home-made, and that designed for the cable cars is shown in Fig. 6. It is of the stationary type, and is constructed from steel springs bent and arranged as shown in the engraving, the outer or front edge being reinforced by a sheath of rubber belting. The design of fender for electric cars is shown in Fig. 7, and was designed and patented by V. T. Lynch, superintendent of the shop. In the foreground the fender is in position for service, while that in the background is folded up against the dashboard. These fenders consist of a frame work of steel tubing, about 1 in. in diameter, and are provided with wooden rods, which are supported in position between thin strips of steel. Near each end on the underside, curved bars are riveted, which serve as runners for lifting the fender over rough places when it strikes the paving. The upper portion folds against the flat portion, when both can be turned up in position, as shown. A simple bracket on each side of the platform under the dash serves to hold the fender in position. It is attached to the platform by an elbow-shaped casting, having a spiral spring, which gives to the fender the proper tension, so that when a body strikes the fender it will move down and back, preventing a sudden shock when it is again lifted in position by the spring. Two brackets under the bumper, with small hooks, as shown, assist in holding the fender in position and provide for a quick adjustment or for a release when it is necessary to fold it up. There are also two chains by which the device, when folded, is attached to the dash rail. These fenders are very light, are constructed at little expense and are claimed to be working in a very satisfactory manner, having picked up without injury quite a number of persons. It is also noted that since the fenders were adopted there have been less accidents from collision with vehicles, the motormen being more cautious than when fenders were not employed. It is the practice of the company to charge the motormen with all damage to the fenders, unless they can prove that a collision was unavoidable.

Among other safety appliances employed on the trains of both the North and West Chicago systems are guard springs, in sets of five, placed between the grip-car and trailer and between the trailers on the right-hand side of the train, Figs. 6 and 8. These springs, together with the method of attaching them to the dashboard, were designed by the general manager of the two systems, J. M. Roach, and have been patented by him. These spiral springs are made of No. 5 wire, and are 26 ins. in length and $1\frac{3}{4}$ ins. in diameter, and are attached to a hinged bar placed against the dashboard, as shown. On the trains that do not run the same end forward all the time the springs are attached to hinged bars, which can be removed by lifting them up out of the carrying sockets, so that any set of five springs can be moved from one side to the other without detaching the individual springs. In rounding curves the springs stretch sufficiently to permit of the relative adjustment of the cars and always form a safeguard to prevent people falling between the trail cars.

Permanent guard rails, together with metal guard strips, have been attached to the outside of all open trail cars. These, as well as the springs above described, are also il-

lustrated in Fig. 8. At first only the two wooden guard rails, as shown, were employed, but it was found that venturesome passengers would frequently attempt to board or leave the car by passing under the guard rails between the seats; hence the necessity of providing the metal strips, as shown.

Practice in the Repair Shops of the Chicago City Railway Company

TROLLEY WHEEL TURNING DEVICE

Fig. 1 illustrates a rapid method for turning the grooves in trolley wheels, as employed in the repair shop of the Chicago City Railway Company. A Reoric & Ayer milling machine is employed, to the bed plate of which the groove cutting device is attached. This consists of a frame work having a pair of movable heads, each of which carries a cutting tool shaped to correspond with the desired groove in the wheel. These cutting tools are placed one on each side of the trolley wheel, one just above and the other below the center of the shaft or mandrel which carries the wheel. The wheel is placed upon the mandrel, and held in place by a nut which is adjusted by hand; lugs cast on the back of the wheel engage the arms on the mandrel and cause it to turn. The wheel being in position, the heads carrying the tools are moved toward each other by means of a right and left screw, which is operated by a crank and gears, as shown in the illustration, so that the groove is readily cut to the desired depth. As soon as finished the cutting tools are caused to retreat by a reverse motion of the crank. The cutting tools are adjusted with reference to the distance from the mandrel by shifting the bed of the milling machine. By the use of this device one man is able to turn out complete fifty wheels in an hour, almost one a minute. Old wheels are turned down in the same manner as new, and the device is readily attached to the bed of the milling machine by clamps, as shown.

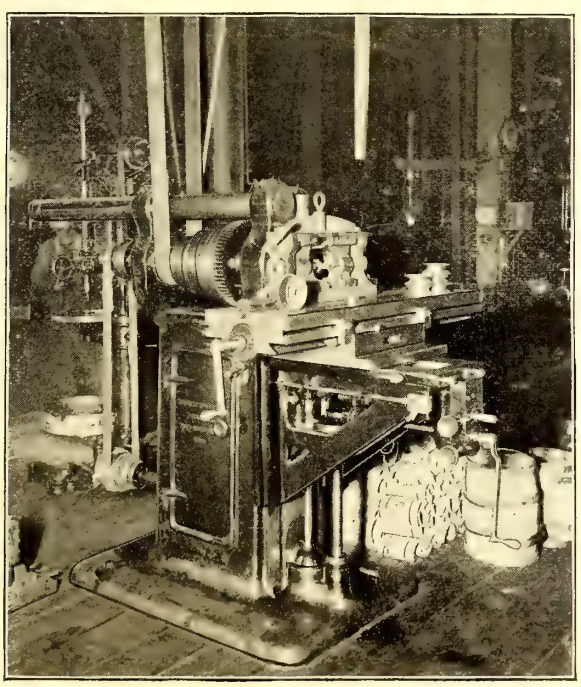

FIG. 1—TOOL FOR CUTTING GROOVES IN TROLLEY WHEELS

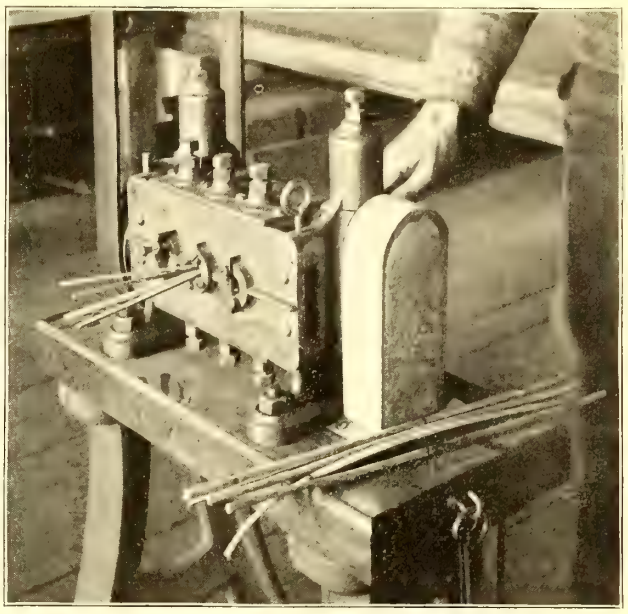
For placing the graphite bushings in trolley wheels a Crossly power press is employed, which is also used for punching and bending purposes. After the bore of the wheel is turned to the proper size, the bushing is placed in position by hand, and then under the plunger of the press, when, by one revolution of the wheel, it is driven half way in; then a large washer is placed on top and a second revolution pushes it home. This work is performed very rapidly, one man being able to place the bushings in four wheels a minute. This method of adjusting the bushings is preferred to that of hammering them in, as the blows from the hammer were found to crumble and dislodge the graphite.



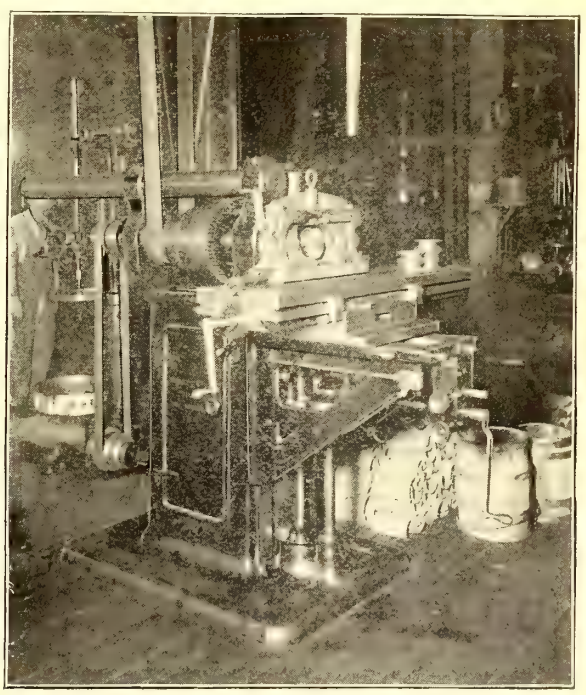


FIG. 2.—RATTAN SPLITTING MACHINE

MACHINE FOR SPLITTING RATTAN

Fig. 2 illustrates a rattan splitting machine. This consists of a frame work of brass with adjusting screws, behind which is a pair of rollers driven by a belt from an overhead shaft. These rollers have three grooves corrugated at their base and of about the size of a rattan. Opposite the grooves, in the outer face, as shown, is a set of knives placed across the tube through which the rattan emerges. There are three tubes and three sets of knives. The first one has a single knife and halves the rattan; the

second has a knife in the form of a cross, and quarters the reed; the third and last splits the reed into three parts. There is a funnel-shaped mouth on the side toward the attendant, and the reeds are fed into the different cutters according to their size. The small ones are halved, the medium size split into thirds, and the large ones are quartered. The reeds are first cut into suitable length for making the brushes for the sweepers and are fastened in bunches in holes in the back by means of rosin cement. The brooms are not formed by doubling the rattans and placing the two ends of a bunch through, as in ordinary practice, which results, as is well known, in the waste of a great deal of stock, but singly, as described above. By the process of splitting and using short reeds, the life of the brooms is greatly increased.

COIL TAPING STANDS AND BOBBINS

Fig. 3 illustrates different forms for holding coils to facilitate taping. These forms consist of a plain board having strips of different shapes nailed on the top, which form grooves to correspond with the shape of the different coils. The coils are held in position by buttons. These forms are mounted on stands having a revolving attachment, so that they are readily brought in position in front of the operator. A set of different shaped forms is shown on the platform, as are also the parts of forms employed in making the field coils. In connection with the taping stands are shown the bobbins in which the tape is enclosed and which greatly facilitates the winding of the tape about the coils. These bobbins consist of two-part circular boxes, made of wood or metal (light metal like aluminum being preferred), about 4 ins. in diameter. After the tape coils are wound to proper size, they are placed over the stem in the bobbin. The latter is threaded at one end, extends through the cover on one side and is fitted with a thumb screw, by means of which a suitable tension may be placed upon the coil of tape to prevent its running out too fast. There are two methods of adjusting the interior spring to provide the necessary tension; one consists of a slightly dished thin metal disc, which is placed each side of the roll of tape, and as the thumb screw is turned up, pressure is brought against the roll of tape. A second method consists in providing a small roller on a half spring, which, being pressed to one side, allows the roll of tape to be placed in position. Then when the bobbin is closed the tape is brought out over and under a set of four small bars which serve to give it sufficient tension, so that by holding the bobbin in the hand and passing it through the coil there is sufficient tension to form the wraps perfectly. By the use of the bobbin and stands the work of taping the coils is greatly facilitated and a more uniform finish can be secured than by the old method. These forms and bobbins were designed by W. C. Bryant, who is in charge of the motor repair department of the Chicago City Railway shops.

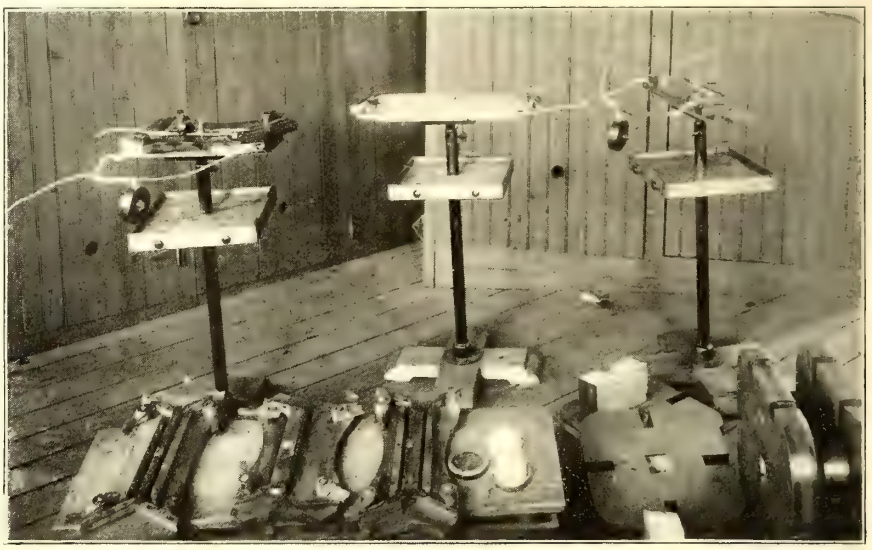

FIG. 3.—COILS FOR WINDING MOTOR COILS

A similar bobbin is also employed for taping car cables. This is made with a very stiff spring, and is mounted on a spindle in a clevis provided with a handle, so that the workman is able to wind the tape very tightly by pulling on the handle of the bobbin after the bobbin is passed once around the bunch of wire.

BAKING COILS

It is the practice in winding motors after the coils are taped to soak them in white paraffine wax. Then, as they are to be placed in the slots of the core, the completed coils are heated in an oven sufficiently to soften the wax and make the coil pliable, so that the wax acts as a lubricant. This facilitates placing the bottom coil in the slot and provides for the use of more insulating material in the bottom of the slot than when the coil is put in without heating.

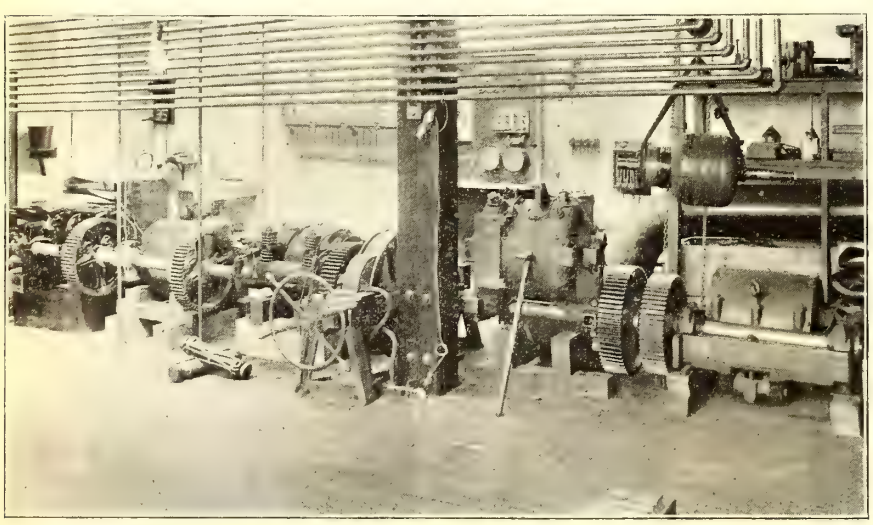

FIG. 4.—ARRANGEMENT OF FIELDS FOR TESTING FIVE TYPES OF ARMATURES

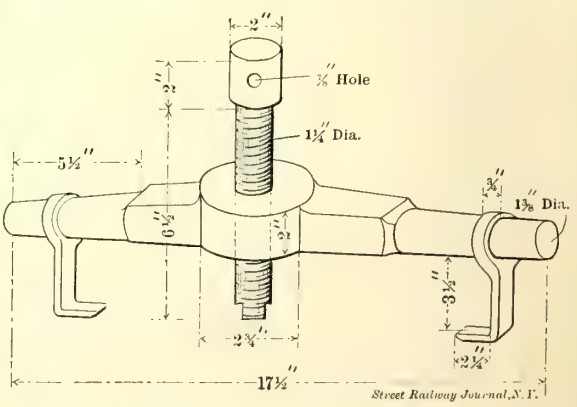

FIG. 5.—SCREW JACK FOR REMOVING FIELD COILS FROM POLE PIECES

ARRANGEMENT OF MOTORS FOR ARMATURE TESTING

Fig. 4 illustrates an arrangement of five motor frames for testing the different types of armatures employed on the lines of the Chicago City Railway. As will be noted, the shaft is provided with gears, into which the pinions from each armature mesh. The current being applied, the motor drives the shaft, and, as this carries a set of brake wheels near the middle, it can be regulated as to speed or power. At the same time the current consumed is registered by the volt and ammeters located on the switchboard, as shown. The braking mechanism consists of two old car wheels with the flanges on the outside, giving a broad braking surface. The brake shoes, which are placed one on each side of the wheel, and which are held in position by forged bars that bend over the axle and around the wheels, are hollow, and are provided with pipes, through which a stream of water is directed, designed to absorb the heat generated by the friction. The brake shoes are applied by means of a screw shaft, operated by a hand wheel, which is shown in the illustration. The covers of the frames are lifted and the armatures shifted about by means of a trolley hand-hoist, which is also shown, having an armature suspended above the frame. The controller, switchboard and resistance boxes are located back of the shaft and against the wall. Every armature, either new or old, is tested before being placed in service. The test for new armatures consists of a run of twenty-five minutes under 55 amps. of current, followed by a ten-minute run at 60 amps. Old armatures, however, undergo a test of only ten minutes with 55 amps.

DIVISION OF WORK

Ten hands, besides the foreman, are employed in the motor repair department, and the work in this department includes, besides repairs, the making of armature and field coils, the making of commutators entire after the bars have been repaired and the slot in the shank milled out, also the making complete of all the resistance boxes or rheostats

FIG. 6.—BRASS FOUNDRY, SHOWING INDIVIDUAL BLAST PIPE FOR EACH FURNACE PIT

employed on the system. The division of the work is as follows: Two men winding new armatures, one man repairing armatures and grounded commutators, (in this connection it is interesting to note that none of the armatures built in the shop has ever become grounded); one man turning commutators and binding them; one boy winding armature coils; three girls taping coils and cutting insulating material; two men building rheostats and repairing controllers, switches and fuse boxes; one man building and repairing commutators; one man winding field coils and repairing old ones, and one boy for miscellaneous work.

For removing a field coil from the pole piece, a screw jack has recently been devised which is made in the company's shop, and one is kept in each car depot, see Fig. 5. This consists of a bar, through the middle of which is a large screw, and on each arm of which is an adjustable hook. To use this jack the hooks are first placed under

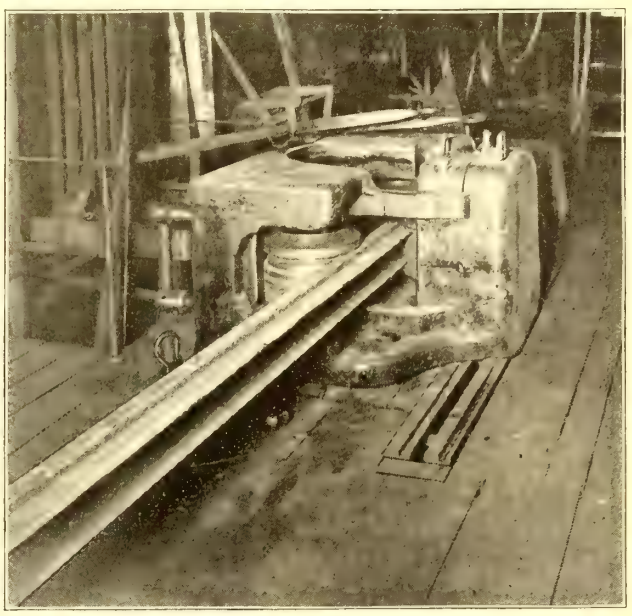

FIG. 7.—RAIL BENDER

the sides of the coil and the end of the screw adjusted to the face of the pole piece, then by turning the screw, the coil is readily drawn off from the pole.

About 1000 motors are employed on the system, and these embrace seven types, including the Westinghouse 12-B, of which there are the greatest number, Westinghouse 12-A, Westinghouse No. 3 and No. 49, Walker No. 5 and G. E. 800 and G. E. 52.

NEW FORM OF RHEOSTAT

A number of the motor cars of the Chicago City Railway Company are being equipped with a new form of rheostat, and in some cases with a double rheostat, especially those on lines of heavy traffic and where trailers are hauled. With the old form of rheostat the life has not been more than two and one-half to three years, and it was found that in 80 per cent of those burned out the short circuit occurred on the last half of the resistance. At the same time a good many burn outs occurred on the first half on lines where there were grades and the cars were held up by excessive street traffic, or when it was necessary to run a long distance on the first two notches. In order to provide for these contingencies and after experimenting with various types of rheostats, the electrical engineer of the company became satisfied that the most successful type of rheostat at present was that constructed of soft steel ribbon with ample carrying capacity (*i. e.*, at least from 25 to 30 per cent more current capacity than ordinarily needed), and that the last half of the rheostat should be of heavier ribbon than the first half, as ordinarily this portion carries current for nearly double the time than the first half. With

the new construction he expects to get three times the life out of the new rheostats than was formerly possible. The two rheostats to be used are known as No. 1 and No. 2, and are made up as follows: No. 1 is composed of six panels of specially made soft steel ribbon. In the first three panels the dimensions of the ribbon are .019 ins. x 0.562 ins., and the last three are made of .028 ins. x 0.625 ins., having nearly double the capacity of the former. The first four panels the dimensions of the ribbon are .019 ins. x 0.562 ins., No. 2 rheostat is composed of six panels, in which the ribbon is .028 ins. x 0.625 ins., which are connected in multiples of two, so that the connections for the two are as follows: R^1 to R^2, four panels in series; R^2 to R^3, eight panels in multiples of two, making the resistance as follows: R^1 to R^2, 3.3 ohms; R^2 to R^3, 1.2 ohms; R^1 to R^3, 4.5 ohms. In the manufacture of No. 1, 43 lbs. of steel ribbon are used, and 8 lbs. of asbestos installation. For No. 2, 45 lbs. of steel ribbon are employed, with 8 lbs. of asbestos. The layers of ribbon of which the rheostats are composed are formed from the coil on a forming board in panel style. This is a board about 12 ft. long, having flat steel pins on each edge a short distance apart. About these the ribbon is wound in zig-zag form by hand, and when necessary the ends are spliced, making a lap of about 2 ins., with parts riveted together. Being bent in proper form, the panels are removed from the forming board and placed upon a table, when strips of asbestos, which have been cut to the proper width, and which are about 1-32 in. in thickness, are placed between the folds or the loops composing a panel. The whole is then placed in a specially designed iron vise or press, in which a pressure of about ten tons is secured against the coil by means of two screws, which are operated by means of a crank placed upon the head. This press is laid flat upon the table, and being fastened in position, the folds are pressed very closely together and held in position by a yoke or clamping device which is placed over the coil by means of slots in the press. The panels are then placed in the forms or frames, and two frames are used in place of one because a single frame would be too heavy to handle.

The rheostat formerly used consisted of six panels of iron ribbon of two thicknesses, one being .017 in. x $\frac{3}{4}$ in. wide; the other .02 in. x $\frac{3}{4}$ in wide, which gave a resistance of about 4.2 ohms, which was divided as follows: R^1 to R^2, or the first contact to the second contact, 3.8 ohms; R^2 to R^3, 1.12 ohms. The amount of ribbon used was 40 lbs., with 7.5 lbs. of asbestos, which was in strips $\frac{7}{8}$ in. wide x 1-32 in. in thickness.

It is thought that the rapid rusting of rheostats is due to condensation while in the barns over night, as they come in off the road warm, and as the barns are usually damp, the condensation is excessive. Rapid rusting follows, and results in short circuits and burn outs.

BRASS FOUNDRY

Fig. 6 illustrates the furnaces and crucibles in the brass foundry at the repair shops of the Chicago City Railway. The particular feature for which this illustration is produced is the method of providing an individual air blast for each furnace pit. The air is conveyed from the storage tank in the header pipe located against the wall, and is directed by means of the descending pipes directly into each furnace. Each pipe is fitted with a cut-off slide valve, which regulates the flow to each pit. As has been previously noted, it is the practice in this repair shop to manufacture all the brass and copper work for overhead line purposes or car trimmings. The cupola for melting the babbitt and lead for journal boxes and for lining the cable carrying sheaves is also made here, as are composition metal grip dies, trolley wheels, and, in fact, all the brass and copper supplies that are required.

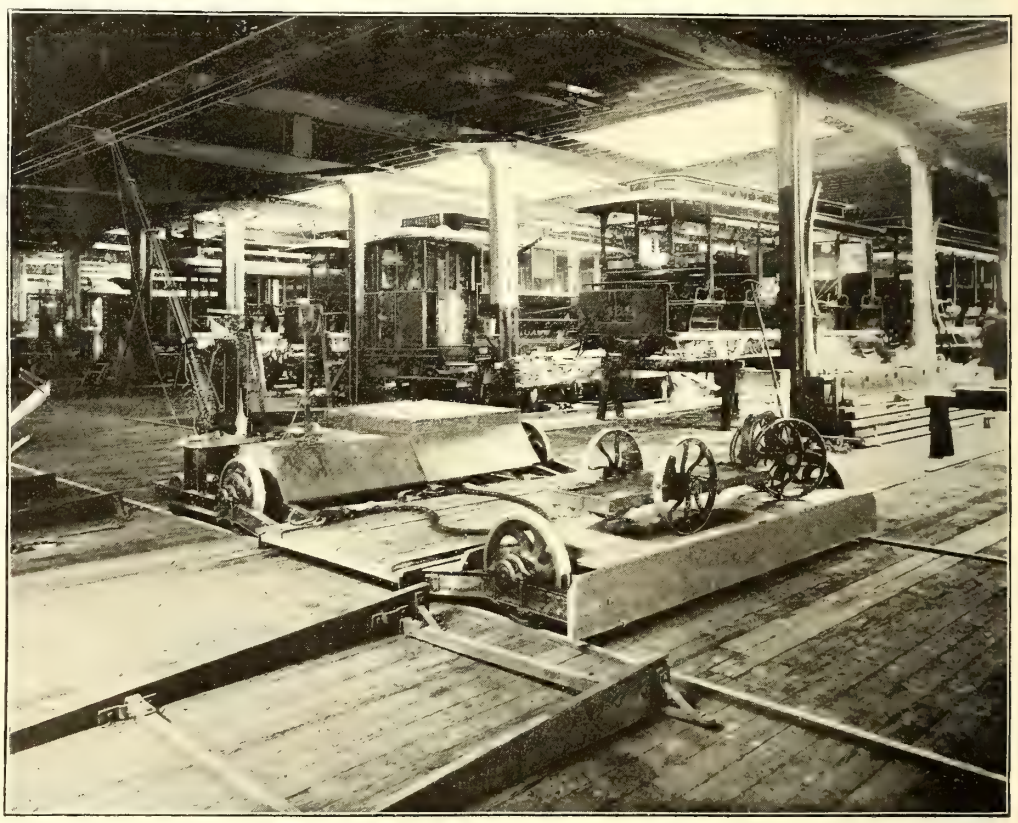

FIG. 8.—ELECTRIC TRANSFER TABLE AND WHEEL TRUCK

RAIL BENDER

Fig. 7 illustrates a power rail bender which is also employed in the same shops. This consists of three cast rollers, which are set vertically in a solid cast frame, but are revolved horizontally by means of shafting and gear placed under the floor and driven by a belt from the main shafting. The rollers are attached to adjustable guides, which slide back and forth in channels in the main casting and the two inside rollers are adjusted by means of large set screws, as shown. The belt is shifted and machine started by means of hand levers placed above the main casting, as shown in the illustration. By means of this machine rails of any size are readily bent to any arc by passing them repeatedly through the rollers. The rails are handled and adjusted by pneumatic hoists.

On the first floor of the wood shop are suspended racks on which the track tools and other repair tools, including the shovels, picks, buckets, hammers and hoes are stored. A careful record is kept of these, and each gang is charged the kits taken out. The rules require that all tools be

returned and delivered to the keeper when each job is finished. This prevents the tools being lost.

In this connection it is interesting to note that all the axes and picks employed on the lines are manufactured in the blacksmith shop of the company.

REMODELED ELECTRIC TRANSFER CAR

A transfer car has recently been remodeled in the repair shop of the Chicago City Railway Company. It is illustrated in Fig. 8, and is now working in a much more satisfactory manner than formerly. The original equipment of

FIG. 9.—STANDARD SINGLE TRUCK CAR

this car was an S. R. G. No. 30 electric motor, and wound for 500 volts circuit. The new equipment consists of a No. 3 Westinghouse, 25 h.p. motor, operated by the type K-2 controller, and in series with the armature are two car rheostats. There is also a two-panel rheostat, arranged in series with the field circuit and designed to choke off the current when the controller is on the first and second notch, after which it is cut out. This rheostat allows the cars to start easily with a heavy load, when it can be speeded up to the required degree. It will be noticed from the illustration that the table is supported by three pairs of wheels on a side, the small one within the frame being an idler, or a plain wheel without shaft or flanges. Current is obtained from a double overhead trolley, and the trolley pole has a wooden harp, which carries two trolley wheels, 14 ins. apart, and the wires lead down each side of the pole, as shown. A G. E. safety switch and a G. E. fuse box complete the electrical equipment. By means of a lever and system of friction clutches a drum is operated on which a rope is wound. This rope leads out onto the platform between two stationary iron pulleys, and is utilized for hauling cars on or off from the table. Triangular pieces of track are employed to lead up to the top of the table.

NEW CAR

Fig. 9 illustrates the new standard closed car designed by the Chicago City Railway Company. This car was briefly described in the July issue, and sixty have recently been ordered from the St. Louis Car Company. The color is seven shades of olive green. The body is 20 ft. long and the car is 30 ft. over all. Both ends are vestibuled and provided with folding doors, made in three sections. The sash is stationary, and the glazing is done in rubber. One of the particular features of the construction of the car is the precautions to deaden the noise. For this purpose double panels are used. The first, or inside, panel, which is attached to the inside of the posts, is in strips $\frac{5}{8}$ in. thick, while the outside panels are of the usual material and the space between is filled with mineral wool. A double floor is also provided, with tar paper between. The upper floor is really Everett matting, and is made of maple. The interior of the car is of stained cherry, with bronze trimmings. All the posts are hand carved, in what is known as the Empire style of decoration. The ceiling is of three-ply birds-eye maple, and the deck lights are of glass known to the trade as alligator pattern. Longitudinal Hale & Kilburn seats, upholstered in Wilton brussels, are employed. Hunter destination signs are mounted above the hood at each end, as shown, and are operated by means of a shaft depending from the ceiling of the hood.

TRUCKS

The cars are mounted on the Moore trucks, which were designed by C. E. Moore, master mechanic of the company. This truck differs essentially from the ordinary motor truck in that the frame work is chiefly of wood, instead of metal, the side bars being of Georgia pine, $3\frac{1}{2}$ ins. x $4\frac{1}{2}$ ins., reinforced on the outside by $\frac{3}{8}$-in. steel plate. There are no metallic springs employed for supporting the body, but the body rests on rubber cushions, as shown. There are two spiral springs in each yoke, and they carry the load. These trucks have an unusually long wheel base, the standard being 9 ft., and to facilitate rounding the curves a link motion is provided for the axle, the link being so attached as to permit a side movement of $2\frac{1}{2}$ ins. for each axle. Inside brakes are used, so as to avoid the use of brake

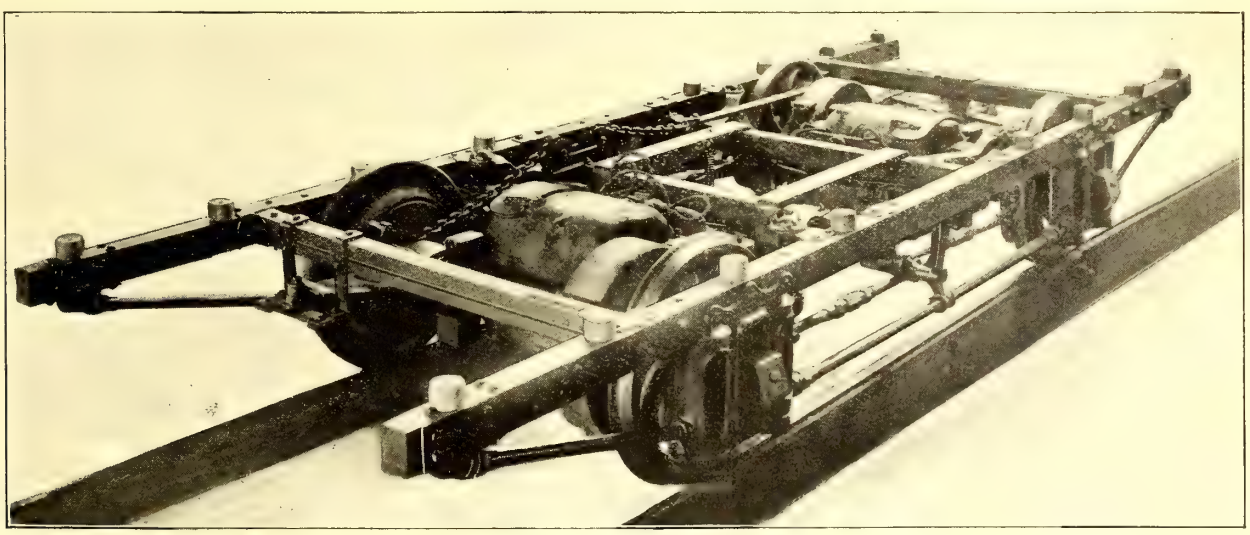

FIG. 10.—STANDARD MOTOR TRUCK

beams. They are operated by means of a tumbling shaft, which is supported by pendent brackets attached to the middle of the side bars. This bracket has a slotted hole in which the tumbling shaft revolves, providing for perfect equalization of brake shoe pressure. The wear of the brake shoes is compensated for by means of turn buckles in the connecting rods. The brake shoe holders are supported by means of pendant ball joint rods, which are attached to brackets bolted to the inside of the side beams. These supporting rods terminate in balls which are held in cast sockets, giving a universal movement to the shoe. Power for operating the brakes is obtained by means of the Price friction device, which is shown in position on the inside of one of the wheels and which has frequently been described in these columns. Power is transmitted to the tumbling shaft by a chain which droops between two rollers and passes beneath a roller on an arm of the tumbling shaft, which is lifted up by the application of the brake.

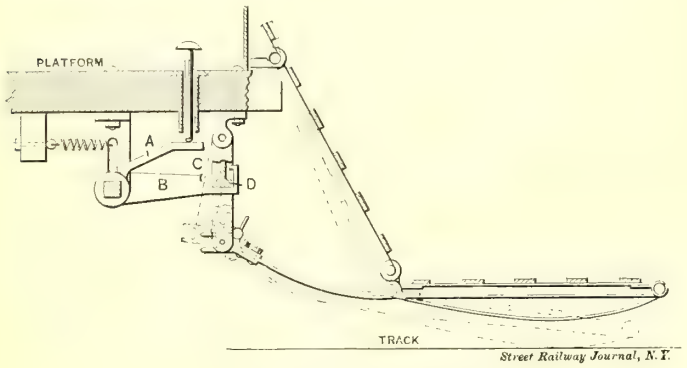

FIG. 11.—STANDARD FENDER

This arm is attached to the tumbling shaft by means of a ratchet arrangement, which provides for adjustment to compensate for wear on shoes. There is also a second arm to which a spiral spring is attached for releasing the brakes. The brake mechanism is also so designed as to work the brakes on the trailer at the same time, and when this attachment is in use, a second release spring assists in unwinding the chain from the friction drum.

Two bolts in each yoke support the pedestal binder and hold the spiral spring in place. These bolts are removed by taking off the bottom nuts. The top of the bolt can then be removed sideways to allow the head to be drawn out through a hole in the top of the cap adjoining and opening into the hole through which the bolt passes when in position. By this means the springs may be drawn down out of the pedestal yoke, when, by removing a nut from each corner brace and disconnecting cables, the truck can be readily dismantled.

The trucks are equipped with what is known as the Anti-Hot-Box Journal Bearing, and the oil box has an improved cover, which is absolutely tight. A large number of these trucks have now been in service on the lines of the company for over two years, and have given such universal satisfaction that they have been adopted as the standard, and the company is now building 200 in its own shops. It is claimed that the long wheel base will prevent teetering, while the body is supported throughout nearly its entire length. By the use of the yoke principle, a swing motion is secured, which allows the truck to round sharp curves without strain or undue wear on the wheel flanges.

FENDERS

Owing to the requirements of a recent city ordinance the cars, to the number of 1200, have all been equipped with fenders, which are illustrated in Fig. 11. These fenders were designed and patented by A. G. Carlson, chief draughtsman of the company. They are of the type known as folding fenders, and are supported by brackets placed under the platform. These fenders are light and strong, being built on a frame work of steel tubing known as structural steel tubing, the seam not being welded. The body of the fender consists of wooden slats, made of elm or hickory, and are 2 ins. wide by $\frac{3}{8}$ in. in thickness. On some of these fenders a wide slat is employed and park advertising signs are printed on this slat in white letters. The slats are attached by means of small bolts and nuts. The cross bars are of crucible steel, and on the under side are two curved bars or runners, which serve to lift the fender over rough places. There is also an attachment under the platform which provides for dropping the fender down to the paving. It is operated by means of a foot button extending through the platform, so that the motorman is able to drop the fender quickly, should he think there is danger of striking a person standing on the track. The dotted lines in Fig. 11 illustrate the position of the fender when dropped for action. These fenders, without the platform attachment, weigh only about 80 lbs., but have sufficient strength for picking up a large body.

FIG. 12.—POLE RAISING WAGON

When folded up the fender comes inside the line of the bumper, and is held in position by means of chains and hooks attached to the dash. The construction is such that

the fenders are readily taken off or shifted from one end of the car to the other.

Since the adoption of this fender, in May last, the cars have picked up sixteen people without injury, and in one instance a man and a woman were taken up by a fender at the same time, being caught in an attempt to cross the track.

POLE RAISING WAGON

Fig. 12 illustrates a pole raising wagon employed on the lines of the Chicago City Railway Company, by means of which, in the recent equipment of the State Street line for electric traction, a crew of seven men with two spans of horses are frequently able to raise and place 137 poles a day. This wagon is equipped with a boom, as shown, which may be lowered to any angle by means of the hoisting apparatus on the front end of the wagon. A set of three interchangeable booms are provided, so that the wagon is able to handle any pole up to 65 ft. in length. The poles, after being distributed, are hauled into position by an extra team of horses, when they are picked up by the block and fall attachment, the power being supplied by the extra team of horses attached to the end of the rope. The wagon is then readily put back into position, and the pole is lowered into the hole, after which the wagon and appliances are quickly moved to the next hole. The wagon is so constructed that it can be turned in a short radius and the team moved out of the way of passing cars. A second hoisting apparatus is placed near the rear of the wagon and can be employed for pulling the poles out of a concrete foundation, when, for any reason, it is necessary to remove a pole. This hoist is operated by hand power. The wagon is also employed for loading and unloading reels of wire from the supplying wagons, the boom being canted in such position as to permit of placing the reel in any position on the wagon. The tackle blocks are designed for two loops in the top block and one in the bottom, so that there is sufficient power for lifting the poles and securing quite rapid movement.

This derrick wagon is also used for unloading and piling rails, when it is operated by the windlass. It was found that the cost of unloading rails by hand from gondola cars and piling them in the yard was 39½ cents per ton; now, by the use of the derrick wagon, the cost is only 11½ cents per ton, including the labor and team for moving the wagon.

Splicing Cars in Philadelphia

When the electric lines in Philadelphia were equipped in 1894 and 1895 most of the cars were mounted on single trucks, and measured 18 ft. body. The management has, for some time, been considering the advisability of replacing some of these cars with long cars. The plan was suggested to utilize some of the short cars by splicing two together to make a long car. This has been done with a number of cars, and the results have been most satisfactory. The work was all performed in the shops of the Union Traction Company, and the accompanying engravings show the method adopted.

FIG. 2.—CAR SAWN IN TWO

Fig. 1 shows the car in its original condition. The body, as stated, was 18 ft. in length and had six windows. Fig. 2 shows the car sawn in two, and Fig. 3 with the two ends separated, ready to receive the piece which is built in the middle of the car. As will be noticed, the side sills are cut apart on a dovetail and the interior framing of the car has been entirely removed.

Fig. 4 shows the car with the sides spliced by the introduction of a sill insertion and two additional panels. The frame has also been completed and the car is ready for the

FIG. 1.—ORIGINAL 18-FT. CAR, AS USED ON THE LINES OF THE UNION TRACTION COMPANY

FIG. 3.—TWO HALVES OF BODY DRAWN APART, READY FOR SILL INSERTION

sheathing. As the sills in the new car are used only to hold the uprights, and are not depended upon for strength, a large steel angle is fitted to each side, as shown in Fig. 5. This angle forms the real sill of the car. In addition to the angle iron, a truss is placed behind the seats to reinforce this angle. The end of the truss rod is shown below the angle in Fig. 6, which represents the car in its finished condition, ready to receive the trucks. The cars, when

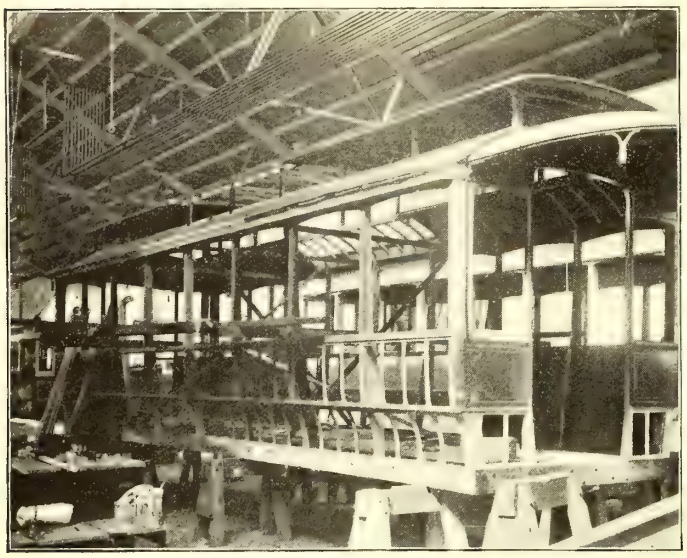

FIG. 4.—VIEW AFTER INSERTION OF PANELS

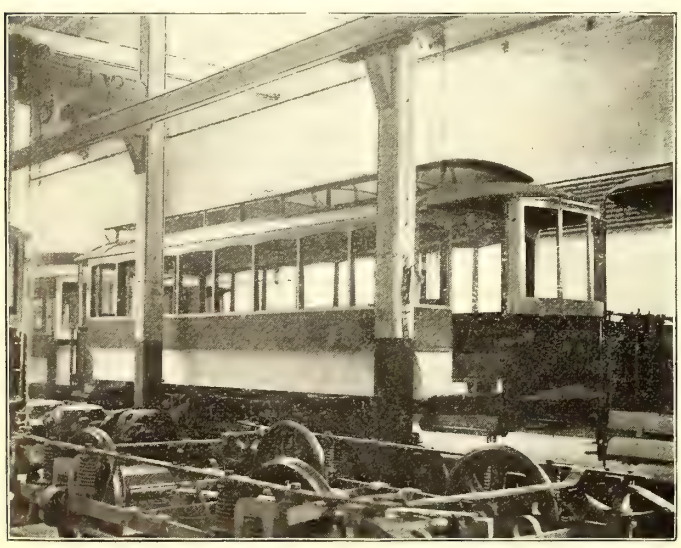
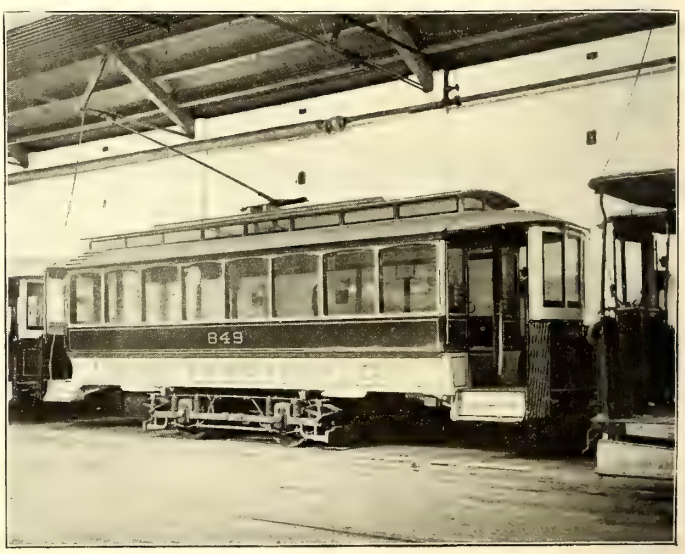


finished, have a 24-ft. body, the length being increased just one-third. When in use they are not carried on the single truck shown in the engraving, but on Brill maximum traction trucks.

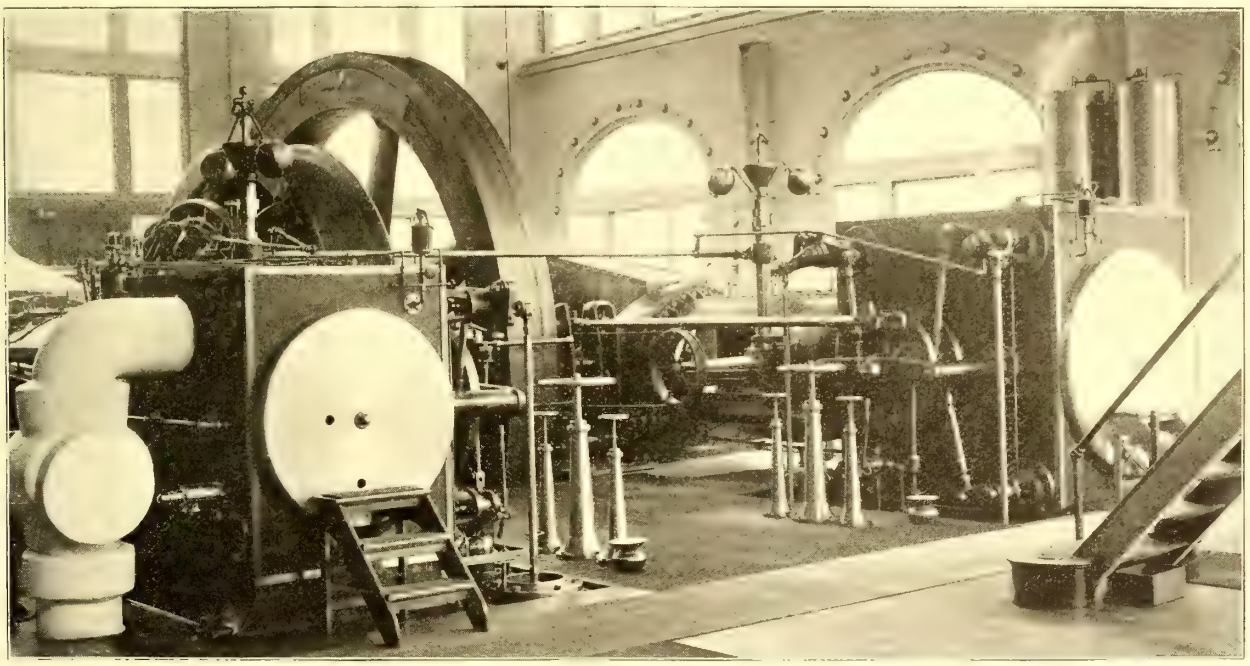


Off-Hand Trolley-Pole Repairs

Accidents to trolley poles are frequent, owing to the liability of the wheels to jump the wire. The force of the spring is sufficient to bend the pole badly, or even to break it in two, if an obstruction of stability is encountered during the rebound of the pole. Usually, the damage done consists of a plain bend near the middle of the pole, and this is allowed to remain as long as it is not great enough to prevent the wheel from staying on the wire when passing under intersecting overhead rigging.

Sometimes a pole receives a green bend which has the effect of twisting it so that the wheel stands at a considerable angle from the vertical. This is frequently so bad that the wheel will not stay on the wire. A rough and ready cure for this is to place a switch iron through the Y of the trolley yoke, then using the iron rod as a lever, twist the pole until the yoke stands true with the wire again.

Sometimes a pole becomes bent close down to the socket. A quite slight bend here, will bring the trolley wheel so low that the springs have not sufficient reserve force to keep the wheel in place. In such a case, take the pole down, thrust the butt-end into a casting underneath the frame of the car, then put two men on the free end of the pole and let them pull slowly, but steadily. If the pole be bent more than one way, straighten all the crooks and turns into one plane before trying to get them out, then the bends can be taken out for good. Care should be taken to so place the pole that the end is not jambed or dented to the extent that it will not go into the socket. Avoid this by a judicious placing of the pole in the casting, across which the purchase is taken. A little attention paid to this matter may save a pole which would otherwise be spoiled for further use.

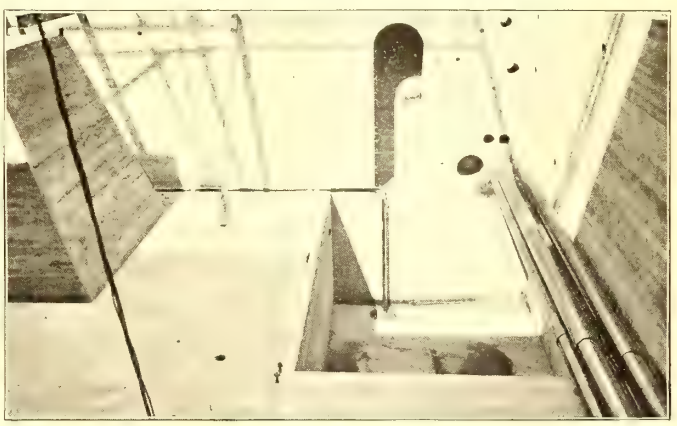


FIGS. 5 AND 6.—COMPLETED CAR

Taxing Street Railways

The opinion of the "Boston Herald" on the subject of street railway taxation is expressed in a recent editorial as follows: "Suppose it were possible for a city to collect, say, $400,000 in public franchise taxes each year from a street railway system. This money would then go into the treasury and would be a relief, to that extent, of the ordinary burden of taxation. On the other hand, if, instead of collecting this tax, the municipality compelled the street railway company, in consequence of the franchise given, to run more frequent cars, to run these cars to non-paying points, or at times in the night when there was no profit in maintaining the service, or compelled it to reduce its rate of fare, or give free exchange of tickets in all directions, it seems to us probable that the general benefit derived therefrom would be greater than that secured by having the same amount of money paid into the municipal treasury. It is altogether a question of policy, but to our mind a slight relief granted to a few taxpayers may be of less general advantage than the direct gain of improved transit service which might be enjoyed every day by hundreds of thousands of people."

"Kinks" from Hartford



The Hartford Street Railway Company has recently been making several additions to its power station on Commerce Street. This station was described quite fully in the issue of May, 1895, of the STREET RAILWAY JOURNAL. Its original equipment consisted of Ball & Wood 300-h.p. engines, each belted to a 220-kw. generator. An addition to the capacity of the station having been found necessary, the company decided to try a Corliss engine, and consequently one built by the Pennsylvania Iron Works of 1250-h.p. capacity was installed. The engine is cross compound condensing, and is directly connected to a 800-kw. General Electric generator. An extensive series of tests, which has been conducted by the company, has disclosed but very little difference between the economy of the two types of machines. If anything, the large engine is slightly more economical, but only when running at full load, and this condition can best be assured, of course, by cutting in and out the small machines. Part of this difference can also be accounted for by the fact that the high-speed engines are belted to their generators, while the slow-speed engine is direct connected. The management speaks in the highest terms of both types of engine.

1250-H. P. DIRECT-CONNECTED ENGINE AND GENERATOR

FOUNDATION FOR ENGINE AND GENERATOR UNDER CONSTRUCTION

CONDENSER PIT

In installing the Corliss engine the question of foundations became an important one, from the fact that the station is built on a quicksand, close to the Connecticut River. This made the use of piling impossible, and the construction finally adopted was that of using concrete throughout for the foundation and side walls of the annex to the station in which the new unit has been placed. The work was done by the Hartford Paving and Construction Company. The foundation was constructed by day's work, and not by contract, and consists of 960.3 cubic yds. of Portland cement concrete, requiring 1996 cubic yds. of excavation to be moved in its construction. Atlas Portland cement was used exclusively, and the entire cost of the work was $6,412.39. The foundation is underlaid by a bed of soft clay and quicksand, into which the condenser pit penetrates. There are no piles or similar contrivances under the foundation, and its stability depends entirely upon the weight being properly distributed over the required area.

The engine foundations are battered 3 ins. to 1 ft., and are made solid with the floor, the side walls and pump pit, forming a monolith. All the pipes from the station are carried to the river through a concrete sub-way 10 ft. in diameter, giving plenty of room for access and inspection.

CAR HOUSES

The main car house of the company is located on State Street, near the center of the city. The tracks, which are

9 in. girder rails, are mounted directly on brick piers, 14 ins. x 16 ins., except where there is special work, where the rails are mounted on brick foundations. The piers are spaced about 15 ft. apart, one at each joint and one midway between the joints, and carry the rails on a cast-iron plate.

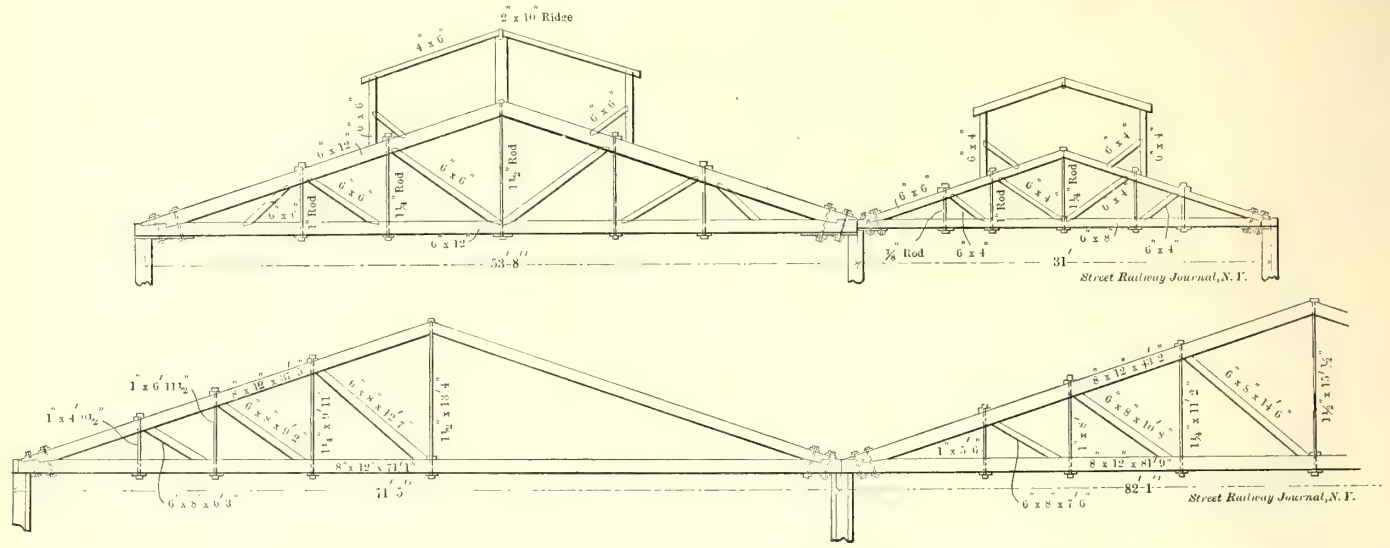


FIG. 2.—WOODEN ROOF GIRDERS—VERNON STREET CAR HOUSE

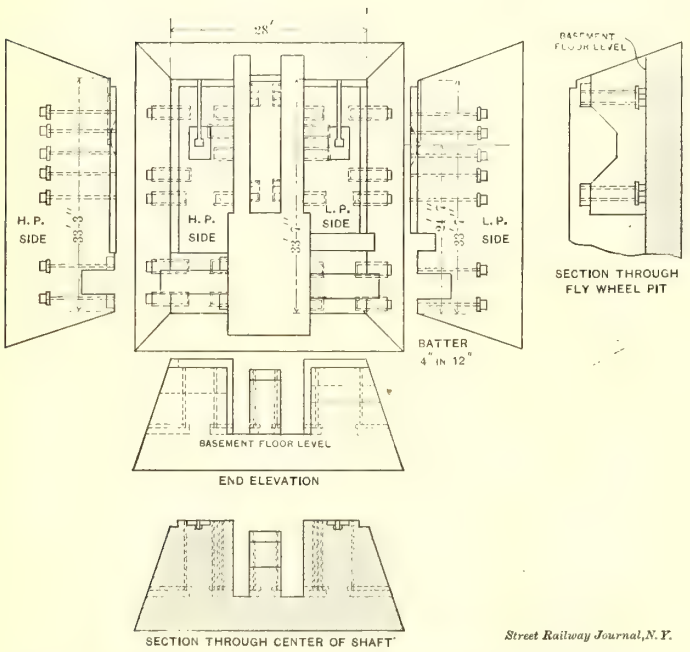

FIG. 1.—ENGINE AND GENERATOR CONCRETE FOUNDATION

They are held to gage by tie-rods, and the space between the rails is planked over, except where room is left for pit work. The floor is concreted, and has a pitch of 4 ins. to 100 ft., this being sufficient to provide for drainage.

The overhead conductors in the car house are steel T bars, which are attached to the roof girders. This makes a very firm running surface for the trolley wheel, and one which is indestructible. For skylights the company is a a very large user of translucent fibre, a very light material which reduces greatly the weight carried on the roof girders. It allows plenty of light to pass through it, and at the same time is unbreakable. The roof itself is the special roofing of the Berlin Iron Bridge Company, by whom the entire structure was built.

The company has also built on Vernon Street a large car house of somewhat different design, which is shown in the accompanying diagrams. This car house is of brick, with track on piers, as in the main car house. The roof girders, however, are of wood, and include one span of 82 ft. 1 in. At this place are also the repair shops and storerooms of the company.

STORAGE OF OIL

The oil for the headlights is stored at the main car house

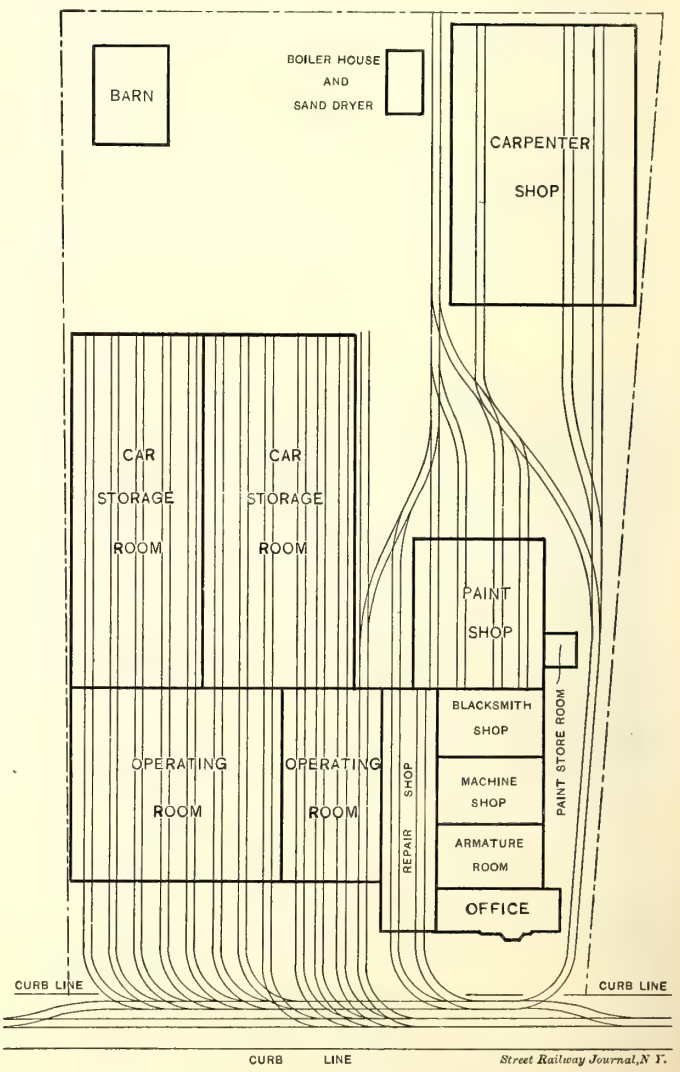

FIG. 3.—PLAN OF BUILDINGS—VERNON STREET

in a galvanized iron tank, which is buried in the ground near the car house. This tank has a capacity of 7 barrels, and when needed, oil is drawn from it by a hand pump. Underneath the pump is a drain, so that the waste oil runs

back into the tank. The placing of the supply of oil underground avoids all danger of fire.

EMPLOYEES' ROOMS

Above the State Street car house are rooms devoted to the use of the conductors and motormen. They are especially large and commodious, and include a meeting room, occupied by a club composed of the employees of the company. The room contains a piano, billiard table, etc. The club is organized as a benefit association, and membership in it is entirely voluntary. In the conductors' room the tables, at which the conductors sort their change, are arranged with low cross partitions, so that when several conductors use one table the coins do not become mixed.

TESTING CAR

The general manager of the company, N. McD. Crawford, has equipped one motor car for testing the apparatus

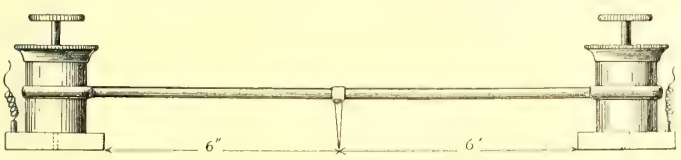

FIG. 4.—CONTACT DEVICE FOR TESTING BONDS

and equipment used on the road, and reports that the results secured by careful testing have saved the company many hundreds of dollars. The car is equipped with all the usual testing apparatus, including a Herrick testing set. This car is being used at present for the conduct of a careful series of tests on every rail bond used on the line. These tests are made after 12 o'clock at night, when the operation of the road has stopped. One hundred amperes are passed through each bond, and the drop in voltage is carefully noted by a milli-volt meter. If this shows a greater drop in voltage than $1\frac{1}{2}$ milli-volts an investigation is immediately instituted. The method of making contact with the rails was a problem upon which considerable thought has been expended. The device finally adopted was the invention of Mr. Crawford, and is illustrated in the accompanying engraving. It consists of two hard-rubber cylinders, connected rigidly by a rod 1 ft. in length. There is a pointer at the center of the rod, so that when this pointer is placed over the joint each contact point will be 6 ins. from the joint. The rubber cylinders terminate in two copper blocks, $2\frac{1}{2}$ ins. x 2 ins., and the top of each is fitted with a screw plunger. The cylinders are filled with mercury, which can be forced out of a minute hole in the center of the blocks by screwing down the plunger.

The rails are first cleaned by an H. P. Brown amalgam stick, after which the contact device is set on the rails, and the plungers screwed down slightly so as to force the mercury out from the cylinders through the bottom of the copper contact blocks, making excellent contact. The entire time required to set the apparatus and make a bond test is only three to four minutes.

ADJUSTABLE WATER RHEOSTAT

The car is fitted with an adjustable water rheostat, consisting of a barrel containing the negative plate at the base of the barrel. The positive plate is raised and lowered by a windlass, which can be set to hold the plate in any position. The barrel is covered, and a stone pipe leads from it to the outside of the car, so that all fumes, produced while the current is being passed through the rheostat, are conveyed outside of the car.

STORE ROOMS

The store rooms of the company are located at the Vernon Street car house, and a careful record is kept of all material which goes into the store room or is issued from it, with the price at which the material is charged in and out. One man is made responsible for all of this material, and does not issue any supplies except on written requisition. A separate compartment is devoted to each class of material. On each box is attached a card, shown herewith. This gives the name of the article, the unit in which it is bought and issued, i. e., pounds, individual pieces, dozen, etc., the maximum and minimum quantity ordered at one time to secure the most advantageous price, the amount of the material received or delivered at any date and the balance after each removal or delivery. From the latter, of course, an inventory of the shop rooms can be speedily obtained. The boxes containing the material are so arranged that the largest boxes are at the bottom, and they then gradually recede towards the top, so that no ladder is required to reach any material in the upper boxes, the storekeeper stepping from one box to another.

SAND DRYER

The sand for the sand boxes is all dried before using in a special heater located over the boiler room. This consists of a hopper, in which are a multiplicity of steam pipes. The sand is raised to this hopper by a bucket conveyor, and after passing through the hopper it is carried by gravity through a chute into the sand cars, of which the company has two. Most of the sanding is done from these cars, although each car is also equipped with De Witt sand boxes. Sand for the individual cars is supplied to the motormen at the different car houses in paper bags, which can easily be emptied into the sand boxes and then thrown away.

FIG. 6.—CARD USED IN ACCOUNTING DEPARTMENT

CHECKING BILLS FOR SUPPLIES

All bills for supplies are checked in the accounting department by means of a card catalogue, one of the individual cards of which is shown herewith. This gives the usual information as to the name of the person from whom the material is purchased, amount received, price, etc., and also the catalogue number, making it easy to order new goods. These cards are also employed for debiting the cost of supplies issued from the store room to the different accounts in the company's ledger.

SPEED CARDS

Special attention is given by the company to insure the maintenance of the running schedule adopted on the different divisions, and for preventing the motormen from running either ahead or behind, a time-table has been drawn

wheels, carrying four 30-h.p. Westinghouse motors, No. 3, and operated by two K 12 General Electric controllers. The car is to be fitted with sand boxes of the company's own make, and is equipped with fenders and four electric signal lamps, placed at each corner of the vestibule over the windows.

It is needless to say that the car is built strong for the uses for which it is intended. The company is well equipped for this kind of work, having all necessary shops and machinery.

Double Deck Cars in Syracuse

The Syracuse, Lakeside & Baldwinsville Railway Company has in operation four double-deck trolley cars, which are giving excellent satisfaction. H. S. Newton, general manager of the company, writes as follows concerning this new rolling stock:

"Our road at present is a summer line, having very heavy traffic at certain times. During last season we had quite a little trouble in handling this traffic satisfactorily with the ordinary type of cars, with trailers attached, and determined this year to make an effort to handle the people more expeditiously in a new way. The result has been the construction of the four double-deck cars above mentioned, which are of the fifteen-bench, open type, very heavily constructed below, and with the upper compartment capable of holding, on a pinch, 100 persons. We have shown our ability on more than one occasion to carry off a good-sized crowd at one load on one of these cars. Altogether, I can say that this class of rolling stock has proven eminently satisfactory."

DOUBLE DECK CARS IN SYRACUSE

Interesting Wheels Records in Los Angeles

There is considerable discussion as to the maximum mileage ever made by an electric car wheel, but if Los Angeles does not hold the record, it certainly comes very near doing so. T. J. Hook, superintendent of the Los Angeles Traction Company, reports that car No. 122, which is 38½ ft. long, and is mounted on Brill maximum traction trucks, recently completed 185,000 miles with the same full set of 33-in. driving wheels. The car weighs empty 11 tons, and the wheels were supplied by the Lobdell Car Wheel Company.

Up to January of this year the only effect noticed from this large mileage was that the flanges of one wheel of each pair had worn somewhat thin, and that the outer edge of the tread was chipped. The flanges were not so thin, however, as to require the removal of the wheels from the car, and the latter were kept in constant service until May 15, when one of the flanges was broken. Both pair were then removed from service, although the wheels at the other end of each axle were as strong and as sound as ever, so far as could be determined from inspection. The piece broken from the flange was about a foot long, and at the ends of the fracture showed silver-white iron. Between the ends the color of the iron was shaded between blue and purple, like that of pyrites of iron and pyrites of copper.

The facts as given by Mr. Hook tend to prove the theory that in most cases where the flanges of motor wheels break, especially after some service, the break does not indicate any defect in the metal, but is incident to the service. The difference in thickness between the flanges on one side and the other of the car must, of course, have been due to the grinding of the flanges against the rails in curving, and the location of the road must have been such as to bring this wear more to one side of the car than the other. This constant grinding on curves may be so severe as to heat the tread and flange of the wheel to an extent sufficient to start a fine crack at the base of the flange. The effect of this is naturally greater with a thin than with a thick flange, as the latter dissipates the heat more quickly. This crack in service gradually extends until a piece breaks out when some sudden thrust comes at that point against the flange.

The chill of a cast iron wheel is composed of crystals which are radial to the chill mould against which they are cast. This can readily be seen from any of the various photographic sections of wheels, which have been published in the STREET RAILWAY JOURNAL. These crystals naturally follow the radius of the flange, and, as the bases of these crystals have a cleavage, they easily separate under the action of heat. That this was the cause of the rupture in the case at Los Angeles is evidenced by the discoloration of the chill to a violet hue, which color can only be produced in the chill by heat. The chilled tread of wheels which are subjected to thermal tests show this conclusively. Another evidence of this is the fact that while a careful examination and the intentional breaking of the flanges of new motor wheels do not disclose the slightest evidence of a crack or any discoloration of the metal, the breaking of old wheels in this way frequently shows a condition of this kind.

STREET RAILWAY JOURNAL

SEPTEMBER, 1899.

PUBLISHED MONTHLY BY

NOTICE.

Papers and correspondence on all subjects of practical interest to our readers are cordially invited. Our columns are always open for the discussion of problems of operation, construction, engineering, accounting, finance and invention.

Special effort will be made to answer promptly, and without charge, any reasonable request for information which may be received from our readers and advertisers, answers being given through the columns of the JOURNAL *when of general interest, otherwise by letter.*

Street railway news and all information regarding changes of officers, new equipment, extensions, financial changes, etc., will be greatly appreciated for use in our Directory, our Financial Supplement, or our news columns.

All matters intended for publication in the current issues must be received at our office not later than the twenty-second of each month.

Address all communications to

The Street Railway Publishing Co.,
Beard Building, 120 Liberty Street, New York.

The October (souvenir) issue of STREET RAILWAY JOURNAL will be a "World's Practice Number," in which will appear a series of papers prepared by leading engineers throughout the world, describing practice in electric railroading in countries where development has been greatest. American practice will be illustrated by several papers upon various branches of the work done in Chicago. Louis J. Magee, managing director of the Union Elektricitäts Gesellschaft, of Berlin, will contribute an extensive and very valuable article upon "Electric Railway Practice in Germany;" Prof. Sidney H. Short will embody the results of his recent close examination of electric railway practice in Great Britain by an article on that subject; and papers upon practice in Russia, Switzerland and Argentina will be contributed by able engineers in the respective countries. The financial characteristics of the large city railway systems of the world will be presented in tabular form, from late and accurate information obtained from original sources, and many other articles of the greatest present interest and value will appear in this number.

There appears to be a somewhat general impression among advocates of municipal ownership who have but superficially studied street railway statistics in our principal cities, that the large street railway systems of New York city are not paying their just burdens of taxation and that, in fact, they are paying almost nothing into the State and city treasury for the privileges which they enjoy. It is not uncommon even to learn from some of these ill advised and irresponsible moulders of public opinion that New York city franchises have been granted to their holders without any compensation whatever—that they have been free gifts to the corporations. The actual facts of the matter, however, as disclosed by a recent careful investigation of the tax records of New York city, are that one system alone is paying over $1,000,000 annually to city and State in the form of taxes upon earnings, real estate and personal property, licenses, etc., and this $1,000,000 amounts to over 8 per cent of the gross receipts. What would be thought if an income tax of 8 per cent was imposed upon the gross income of any citizen, or a tax of 16 per cent upon his net income?

The results of the tests of power brakes to be made this month on certain lines in New York city, under the auspices of the Board of Railroad Commissioners of the State of New York, will be looked forward to with great interest in the hope that a substantial and valuable contribution to existing data upon the braking of electric cars will be brought out. We understand that nearly fifty devices in all are to be tested, and manufacturers of air, electric and mechanical brakes of all kinds are taking great pains to comply with all requirements of the Board and to prepare their apparatus carefully to produce good results.

The coming two months are generally regarded by street railway managers as those in which the pressure in business is lightest upon them, and these months have therefore been generally selected for holding the various conventions. By this we do not mean that the lot of the railway manager is at any time an easy one, for he always has something to think about and worry over; but by the 1st of September the summer traffic has begun to wane, and until the end of October the immediate approach of winter and the holiday season, with their accompanying problems, are some distance off. For this reason the American Street Railway Association and many of the State associations have done wisely to select this time for holding their annual conventions. Of the State meetings, the two most numerously attended are those of New York and Pennsylvania; the former occurring at Ithaca, Sept. 12 and 13, and the latter at Lancaster, Oct. 4 and 5. To both a most cordial invitation by the respective officers has been extended, not only to the street railways of the State in which the convention is held, but to those of other States in case they may wish to attend, and also particularly to the representatives of manufacturers or the supply men engaged in

electric railway business. Both these associations have been most successful, and both have probably never been more prosperous or attained a larger membership than at present.

* * * * * *

It is not necessary at this time to dwell on the benefits which these organizations confer on the industry in general and on their own members. These benefits are too widely known and enjoyed to require further discussion here. There is one benefit, however, which can be derived from them that does not seem to be appreciated as much as it should be; and that is the opportunity which is given to individuals, among lesser known engineers, superintendents and other operating men in the business, particularly to the young men who have only recently engaged in the industry, to introduce themselves and their ideas to the "magnates" of the business. We know from personal experience that there are in the electric railway business, particularly among the small roads, a great many men whose ability warrants their holding more lucrative positions than they do at present. The owners and the responsible officials of the larger roads, on the other hand, are constantly on the lookout for assistants who can aid them in their enterprises. There is perhaps no business in which ideas and intelligence are more required than in that devoted to electric railroading, and none in which a possession of these qualities is more quickly appreciated by the important men in the business. The New York State Street Railway Association, in particular, established several years ago the practice of devoting the major part of its proceedings to short addresses and papers on timely topics. A long list of subjects, covering a wide field in the mechanical, electrical, operating and accounting branches, is published in advance of the meeting, and anyone who wishes to give his views on any of these topics is invited to do so, provided only they are to the point and not too long. In addition, however, it may not be generally known, but should be understood, that if anyone in the railway business has something to say upon any other topic connected with electric railways, not mentioned in the published list, the association would be glad to hear him, and an application to the president or secretary will insure the giving to him of the necessary time. If instead of presenting a paper he prefers to make his remarks orally the discussion is always open to him. What has been stated respecting the New York State Association is practically the same of all State associations which hold open meetings. We again urge, therefore, the bright men of the business to take advantage of the excellent opportunity thus offered to let their light shine before men, take an active part in the State associations to which their companies belong, and show the managers of the larger roads that they are capable of solving the problems which have come before them in the properties under their charge.

A peculiar incident in the testimony given at the investigation of the recent trolley accident near Stratford, Conn., was the evidence submitted by a man named Kelly. He stated that he was on the car at the time of the accident, and described graphically and with great detail his sensations when the car ran off the track, when it climbed the guard-rail, and when it took its final plunge over the bridge into the gorge below. He attributed his escape to the fact that during the descent he fell outside of the car and landed in some mud. During the first few days of the investigation he was regarded with a great deal of interest by the members of the jury and the attendants, including the newspaper reporters. Subsequent testimony, however, proved that he was not on the car at all, but that he witnessed the accident while driving a carriage in the neighborhood. When confronted with this evidence Mr. Kelly did not deny it, but stated that his imagination overcame him to such an extent, and that he had thought so much about what he had seen, that he came to believe he was on the car itself. While in itself trifling, the incident simply proves the proposition which many jurists have held for a long time, that direct testimony is not only not as good as circumstantial evidence, but very often extremely unreliable, especially of events which happen during moments of great excitement. Leaving out of consideration entirely the wish for notoriety, or the desire to participate in damage suits by means of perjured testimony, some people, after a crisis of this kind, are so constituted that they come to actually believe that they have participated in or seen things which never occurred, and the most graphic description of some of the incidents is drawn entirely from their imagination, without any real intention to deceive. This fact is worth remembering in accident cases, and there are many cases on record similar to that cited above.

During the trial of a recent suit for damages brought by a water company against an electric railway company for alleged injury to the pipes of the plaintiffs through electrolysis, the attorney for the water company stated that all of the alleged damages were limited to the territory within 2000 ft. of the railway power station. Soon after this statement, the attorney of the railroad company arose and asked his opponents if their clients would sign a contract releasing the railway company in the future from all claims for damages to the water pipes from electrolysis outside of this district, provided his clients would agree to repair all troubles due to electrolysis within the region specified, viz., that within 2000 ft. of the station. After consultation with the managers of the water company, the attorney of the latter stated that the water company would be perfectly willing to agree to this condition. Before the contract was signed, however, the managers of the railroad company good-naturedly decided to be generous to their opponents and advised them not to sign the contract. When asked why, the railway managers said that if it was signed, they would immediately *reverse their current*, thereby *transferring* any possible trouble from near the station to the suburbs.

Comparative Costs and Profits of Cable, Electric and Horse Traction in New York City

In November, 1898, we published, from the private cost sheets of the Metropolitan Street Railway Company, of New York City, a comparative exhibit of the receipts and expenses in detail of the cable lines, the electric (underground conduit) lines and the horse railway lines of that important system, for the year ending June 30, 1898. We are now able to present, in comparison with these figures, those of the corresponding financial year just ended. The comparison is the more valuable, inasmuch as the track

mileage of the system is the same this year as last, so that the results are not complicated by the purchase of new lines or the building of extensions, but the full effect of the change of motive power and the giving of greater facilities may be seen reflected in gross earnings, while the results of the ageing of electrical apparatus and of certain other influences affecting operation during the year are shown in the detailed operating expenses.

On June 30, 1899, the company had 25.3 miles of track in operation by the cable system, the construction dating from 1893 and 1895; 82.1 miles of track in operation with the underground electric system, nearly all of which was opened from Nov. 1, 1897, to Oct. 1, 1898; and 113.4 miles of horse railway track. It will thus be seen that in both years, the results of which are now presented, there was serious interruption to traffic because of construction, the company last year losing three complete months' traffic on two of its most heavily patronized lines.

The first lesson to be derived from these figures is the way in which the public responds to increased facilities. In the last year the company ran its cars over the same trackage nearly 42,000,000 miles, as against but 35,000,000 miles in the previous year, the new cars being, moreover, nearly double the capacity of the old. The passenger receipts jumped nearly 25 per cent as a consequence, while the receipts per car mile were actually increased from 29.7 cents to 30.7 cents, or about 3 per cent. The traffic of the cable lines fell off about 10 per cent, and of the horse lines about 30 per cent, while the electric lines carried three times as many passengers in 1899 as in 1898, and their receipts per car mile increased from 26.99 cents to 31.23 cents.

Taken as a whole, the Metropolitan system operated last year at 15.18 cents per car mile, as against 15.83 cents in the previous year, and the earnings from operation have become 15.50 cents, as against 13.87 cents for 1898. The electric lines have made all of this increased net earning power, and have, in addition, overcome a combined diminution on the horse and cable lines of 1.15 cents per car mile.

The percentages of operating expenses to passenger receipts of the three motive powers compare as follows:

	1898	1899
	Per cent	Per cent
Cable	47.8	50.8
Electric	37.9	38.3
Horse	65.3	69.8
Total	53.3	49.4

Coming now to detailed operating expenses, we find much to study in the comparisons, and some things which require explanation. The winter of 1898-9 was an extremely severe one, the most so that New York has known since the great blizzard of 1888. It was not only that there were two or three severe storms to contend with, but there was a long succession of stormy conditions, and the snow was not off the ground for weeks at a time. This had a serious influence, not only in the item of "removing snow and ice and street cleaning," which increased from $27,725 in 1898 to $67,322 in 1899, but also in "renewals of cable" for the cable system, "tube cleaning" for both cable and electric systems, "repairs of cars, vehicles and electrical and cable equipment," and in lost traffic, the latter a very material figure, inasmuch as the system was almost completely blocked for several days during the winter. During these heavy snow storms the cable lines were kept in almost continuous operation, but only at the expense of immense strain and wear upon the cables. During parts of the stormy period last winter a new cable on the Broadway line would last hardly more than a week.

As a result of these and other influences, including the ageing of apparatus, there has been a general increase in the cost of all three motive powers in the last year as compared with the previous one, and this increase is found in all of the main divisions of operating expenses with all three motive powers, except in "general expenses" for the cable system, and in "transportation" and "general expenses" in the horse system, which show slight decreases.

It will be noticed that in the power figures of the electric line appear a number of charges belonging to horse railroading, and it is again explained, as was done last year, that these are owing to a short crosstown horse railway line so joining a number of the electric lines as to make it impossible to consider it other than a part of the electric system. The cost of electric motive power proper, excluding these items, was 1.21 cents per car mile in 1898, and 1.57 cents per car mile in 1899. The company's new 70,000-h.p. power station was not in operation at all during the year, and is even now running but a single unit out of the ten to be installed, so that the advantage of economical power has not yet been obtained, but the company has been forced to use a number of temporary power stations with storage batteries, etc., and has been many times forced to work them above the economical limit, the demand for power at certain hours of the day severely taxing the station capacities.

In connection with these detailed figures of passenger operation pure and simple, which are the ones, of course, which will be of special interest to the street railway manager and engineer, it may be well to present a complete financial statement of the operation of the Metropolitan system for the last two years. In this statement the "receipts from all sources" include not only the passenger receipts, but those from advertising, dividends on stock of other companies held in the treasury, income from rental of offices in the power station buildings owned by the company, etc.; while the operating expenses of this statement are slightly larger than those in the accompanying table, by reason of items covering cost of caring for office buildings and a few other small charges. A complete statement follows:

	1898	1899
Receipts from all sources	$11,076,021	$13,525,524
All operating expenses	5,620,484	6,408,711
Earnings from operation	5,455,537	7,116,813
Per cent operating expenses to total receipts	50.7	47.4
Fixed charges	3,609,966	4,477,757
Dividends paid	1,500,000	2,471,675
Surplus over dividends	345,570	167,381

We cannot forbear to again speak of the generosity of the management of the Metropolitan Street Railway Company in freely giving to the engineering and street railway public valuable figures of this kind, thus throwing light upon the problems which both foreign and American cities are grappling with at the present time.

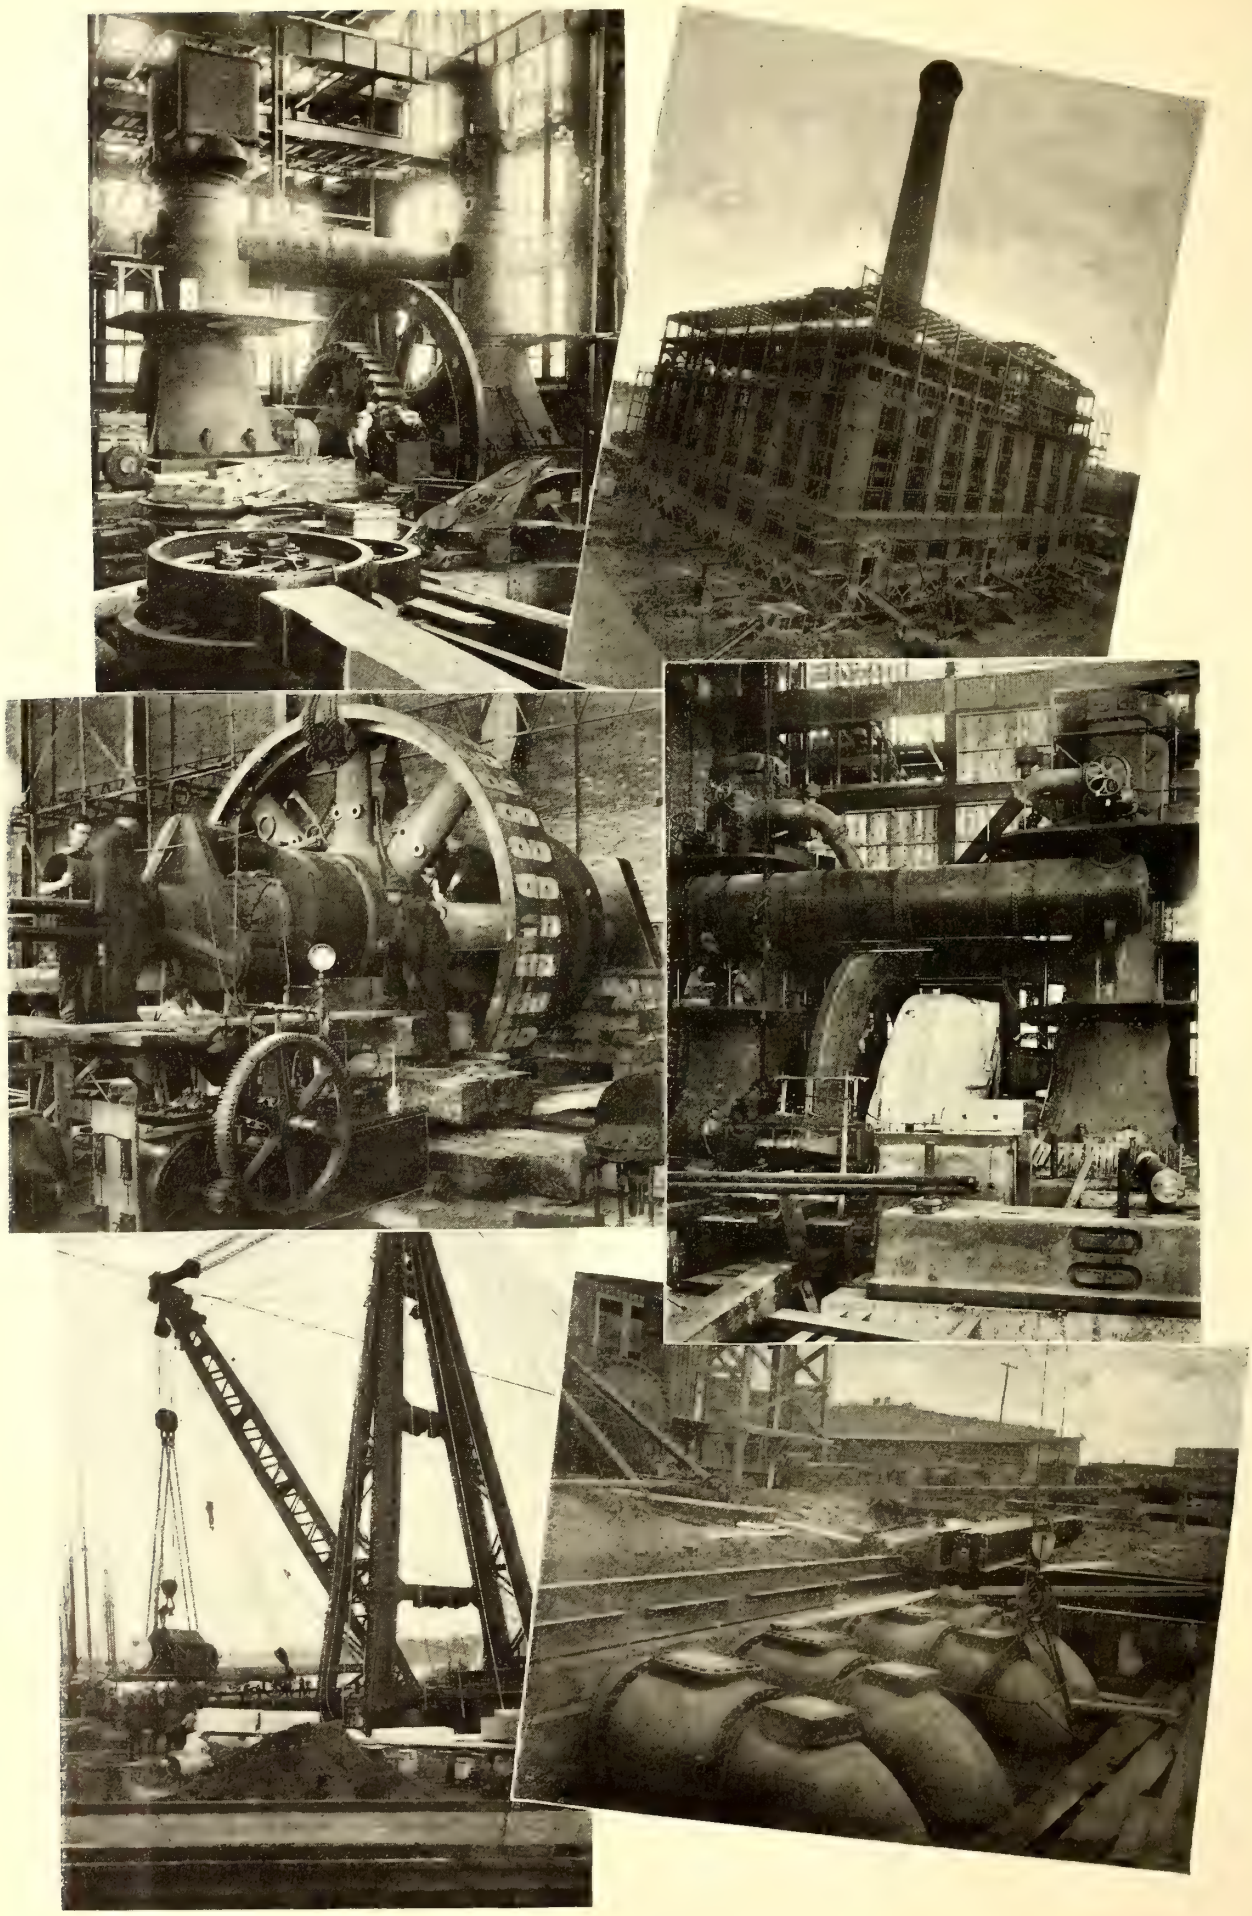
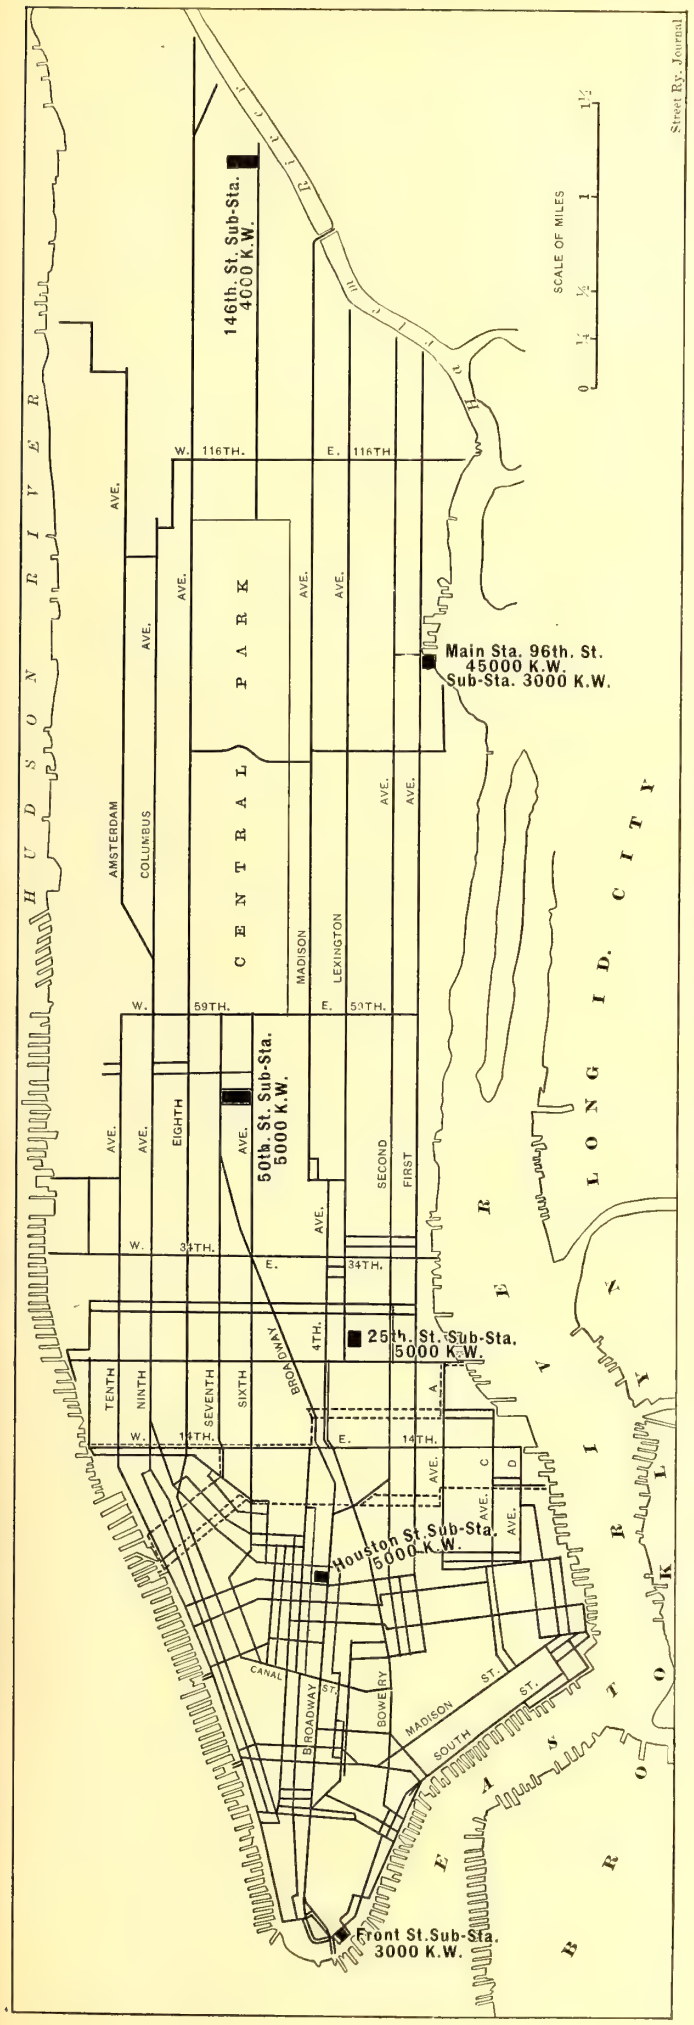
Power Station of Metropolitan Street Railway Company

The work on the main power station of the Metropolitan Street Railway Company, of New York, has been carried on continuously since the construction was decided upon about two years ago, and the building is now nearing completion. Frequent reference has been made in the STREET RAILWAY JOURNAL to the power station, and the fact that during the last month the first of the large engines which are now being installed was turned over by steam makes the present time a fitting one to publish a short description of the work which has already been performed, and to give a number of views showing the present condition of the work.

The station is located on the extreme eastern side of the city, between Ninety-fifth and Ninety-sixth Streets, and First Avenue and the East River. While somewhat outside of the center of distribution, it offers the best of facilities for the handling of fuel and ashes and for obtaining water for condensing purposes. As the alternating system of current distribution at high potential will be used, the losses in transmission, on account of the location of the station outside of the center of gravity, will be trifling compared with the other advantages secured at this point.



VIEW OF NEW MAIN POWER STATION, METROPOLITAN STREET RAILWAY COMPANY, NEW YORK



The building is of brick, with steel trusses and framing, and occupies a space of about 201 ft. by 279 ft. The engine room will occupy the northern end of the building, and will be about 110 ft wide and 200 ft. long on the short side. It will contain eleven vertical cross-compound condensing Allis engines,—the largest of any kind ever built in this country. The cylinders are 46 ins. x 86 ins. x 60-in. stroke, and the distance from the foundation to the top of the cylinder is about 38 ft. 3 ins. The shaft is hollow, being 37 ins. in diameter at the center, and having an opening 16 ins. in diameter extending the entire length. The journals are 34 ins. x 60 ins. The fly-wheels of these engines are 28 ft. in diameter, and are made up with a cast-steel rim 2 ft. 5 ins. deep and 2 ft. 4½ ins. wide, to which are riveted eighty 1⅛-in. steel plates at each side, making 160 plates in all. The engines can develop 4500 i.h.p. at greatest economical load, and will be able to work continuously at 6000 h.p. if required, and for a short time to work at 7000 h.p. Each engine is directly connected to a 3500-kw. General Electric generator. This machine has forty poles, and will have a frequency of twenty-five cycles at 6600 volts, and will operate at 75 r.p.m. At present the engine room contains three Ideal engines for operating exciters, and two 1200-h.p. engines supplied by the Pennsylvania Iron Works for temporary service.

The power room will contain eighty-seven Babcock & Wilcox water-tube boilers in three tiers of twenty-nine boilers each. Each boiler will have a rated capacity of 250 h.p., with (ultimate) capacity of 400 h.p. Over the boiler room, extending the entire length of the building, is a steel coal storage bin, with a capacity of about 9000 tons. The piping is extra heavy throughout, and was installed by the Walworth Manufacturing Company and Best, Fox & Company. The joints are of the Van Stone type, and Walworth valves are used throughout. A Mead coal conveyor is being installed and a Sellers' traveling crane operates the entire length of the engine room.

One of the interesting features of the station is the chimney, which is stated to be the largest in the world and the tallest on this continent. It is 353 ft. in height, with a 22-ft. core. The concrete foundations for this stack are 85 ft. square, and are carried down to a depth of 20 ft. be-

VIEWS SHOWING CONSTRUCTION OF NINETY-SIXTH STREET STATION

MAP OF NEW YORK CITY, SHOWING LINES AND STATIONS OF THE METROPOLITAN STREET RAILWAY COMPANY

low the level of the station. At this depth piles were driven, spaced 2 ft. 3 ins. and 2 ft. 6 ins. apart; 1345 piles altogether were driven in this space, after which the pit was filled with a mixture of one part cement, three parts sand and five parts broken stone, making a block of concrete 85 ft. square and 20 ft. in depth. The chimney, which is built upon this block, contains 3,600,000 bricks and weighs 8540 tons.

The accompanying map shows the location of the substations to be used in connection with the main station at Ninety-sixth Street. These stations run in sizes from 3000 to 6000 kw., as follows: 146th Street, 4000 kw.; Ninety-sixth Street, 3000 kw.; Fiftieth Street, 6000 kw.; Twenty-fifth Street, 5000 kw.; Front Street, 3000 kw., and Houston Street, 5000 kw. The main generating station, as stated, has a capacity of 45,000 kw. Two more stations will probably be located in the lower end of the city a little later, possibly on new plots to be purchased.

Storage batteries will be used extensively, thereby increasing the capacity of the stations, but the sizes of the batteries to be employed have not yet been fully determined.

Important Electric Railway Recently Opened in Switzerland

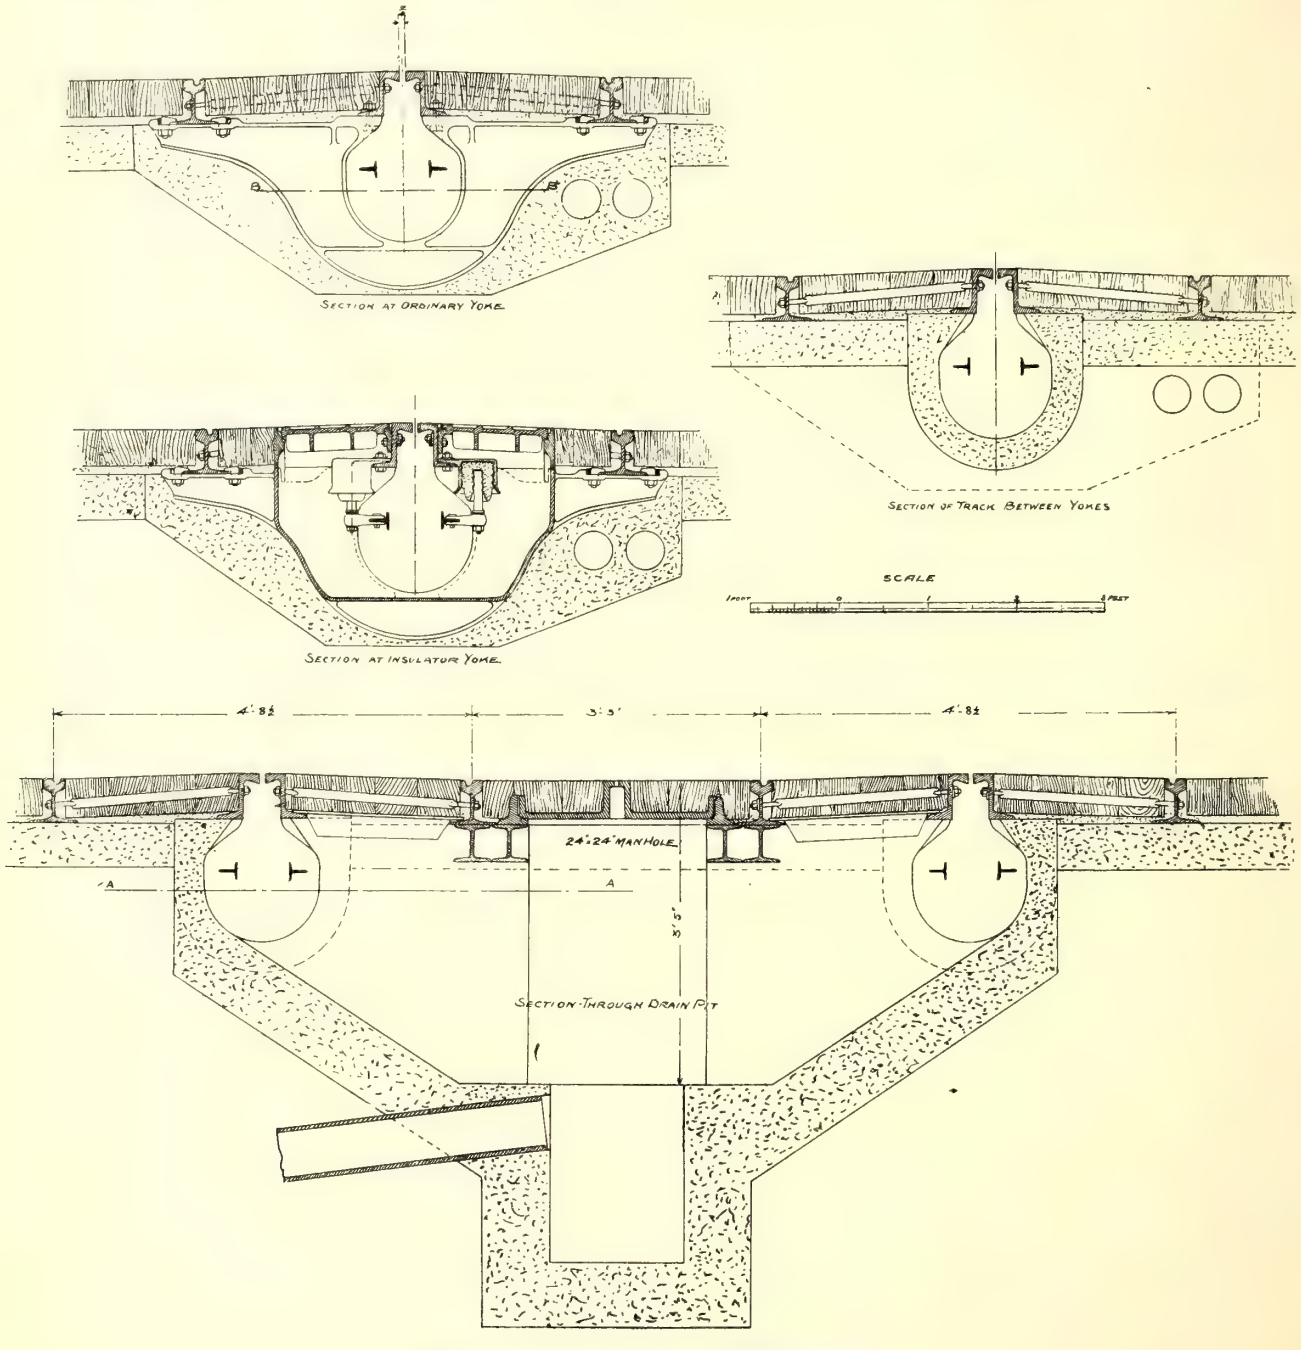
The first electric trunk line in Switzerland was put in operation recently. It extends between Burgdorf and Thun, and is, with exception of the Chavornay-Orbe Road, which is only 4 km. (2.6 miles) long, the first road in Switzerland to be operated by electricity under steam railroad conditions. Up to the station of Hasle it uses the track of the Emmenthal Railroad. From that point it branches off and enters the Biglen Valley, in which are located the villages Schafhausen, Bigenthal, Walkringen and Biglen, and meets the Berne-Lucerne branch of the Jura-Simplon Railroad at Konolfingen. The new road then follows the Kirsenbach River to Thun.

The electric power for the operation of the road is generated at Spiez, on the Thuner See, and is in the form of three-phase alternating current at a pressure of 15,000 volts. The current is led into Thun by lines strung on iron poles, and from Thun to Burgdorf, on wooden poles located adjacent to the roadbed. Fourteen transformer stations, with a maximum capacity of 450 kw., reduce the pressure from 15,000 volts to 750 volts alternating current, which is directly employed for the operation of the road. The trolley line consists of two hard drawn copper wires 8 mm. in diameter, and the rails form the third conductor.

The rolling stock of the road consists at present of six motor cars, weighing 32 tons, and a corresponding number of trailers. The motor cars will seat sixty-six persons. To each one of these cars an ordinary car seating fifty-five persons, of the second and third class, can be attached. The speed is 36 km. (22 miles) per hour. All cars are equipped with hand and Westinghouse brakes, and are electrically lighted. The motor cars are electrically heated, while the trailers are warmed either by electricity or steam.

For the freight traffic two electric locomotives are in service, each of which can transport 100 tons on the steepest grades (2.5 per cent). Each locomotive is equipped with two motors of 150 h.p. each, and can attain a speed of 18 or 36 km. (11—22 miles) per hour. The company also proposes to provide a small equipment of standard steam locomotives for emergencies and times of extra traffic. For this reason steam heating has been provided for in the trailers, besides the electrical method.

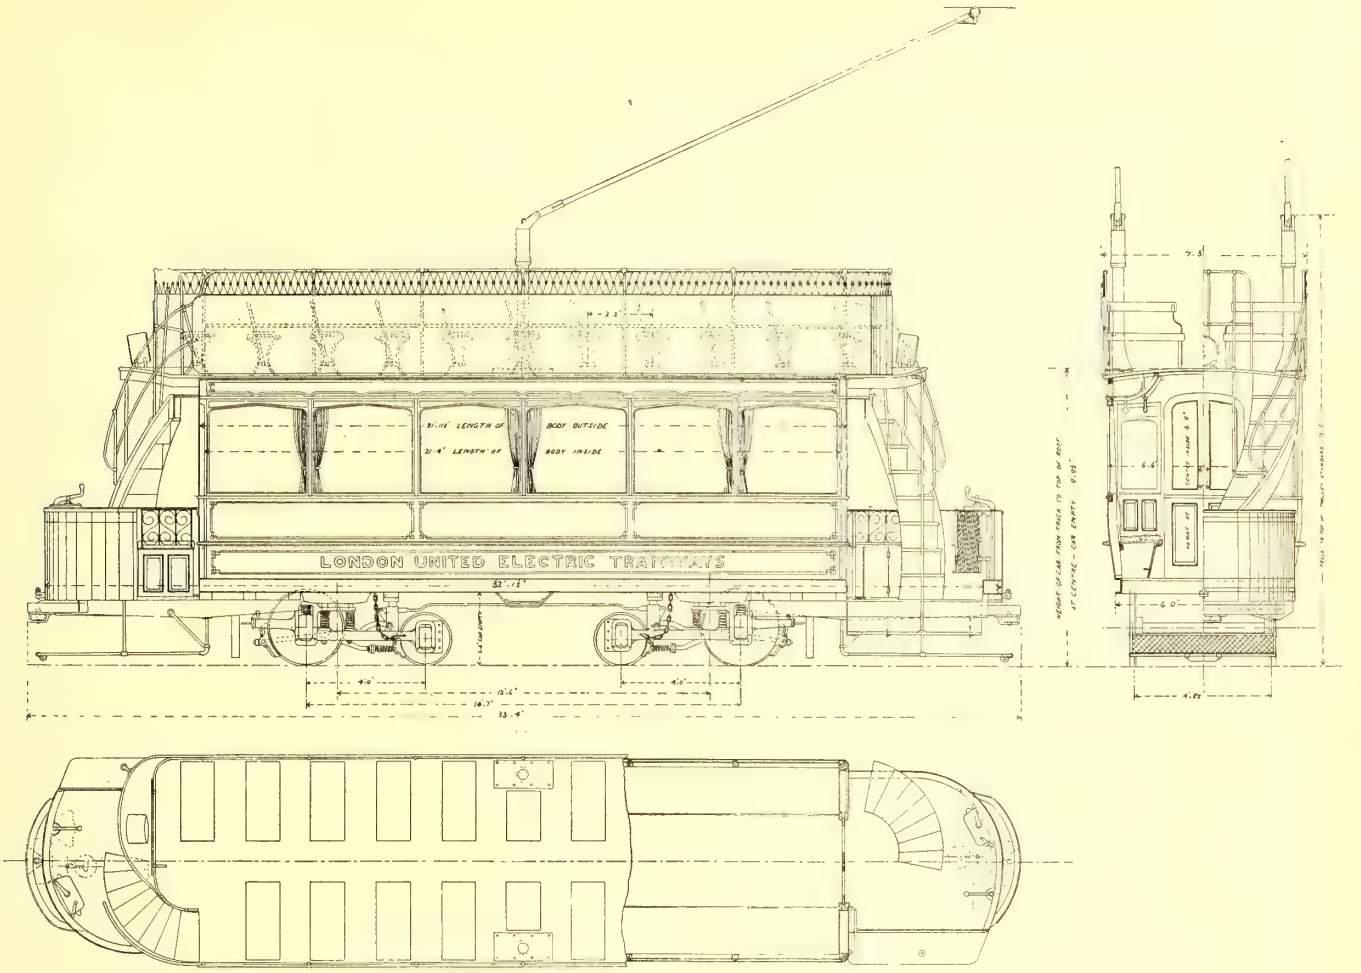
Between Burgdorf and Thun are thirteen way stations. As the line is 41 km. (25.4 miles) long, the average dis-



tance between the stations is 3 km. (1.8 miles), with a speed of 36 km. (22 miles) per hour. Stops are made about every five minutes. The depots are simple in construction, but are, nevertheless, handsome and practical. They are all lighted by electricity.

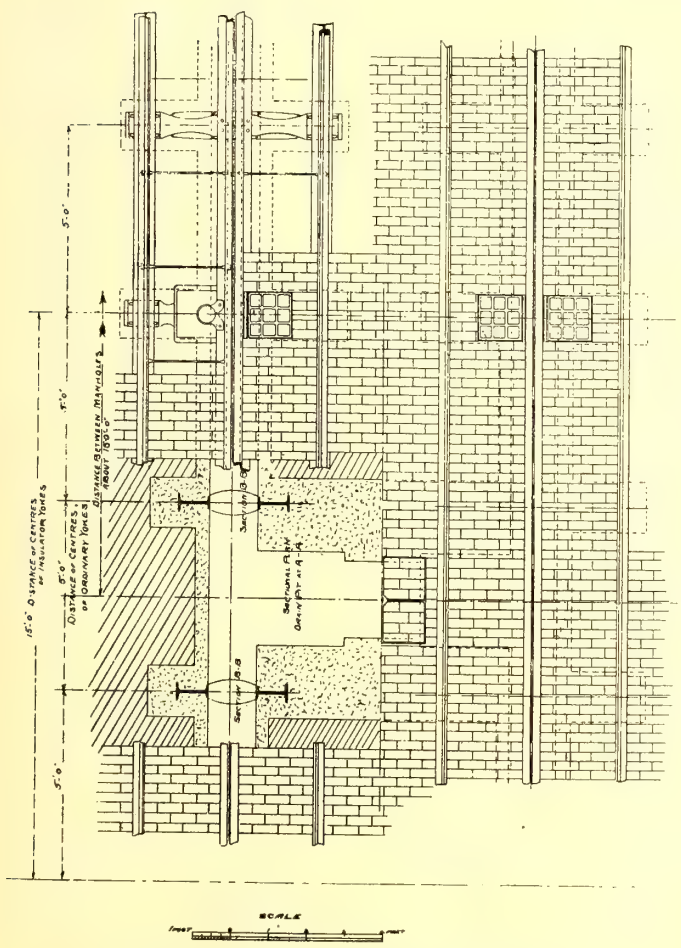
Wages at Hull, England

The City Council of Hull, England, has fixed upon the following scale of wages for its employees: The time required per week is seventy hours, which, however, includes the time allowed for meals. Inspectors receive 30s. ($7.20) per week, and for each year of service one additional shilling per week up to 40s. ($9.60). Motormen start with 28s. ($6.72) per week, and are raised to 35s. ($8.40). They also receive 6d. (12 cents) for each hour overtime. Conductors receive 18s. ($4.32) per week, and are raised to 25s. ($6). For overtime during the first three years they receive 4d. (8 cents) per hour, later 4½d. (9 cents). Barn hands receive 21s to 25s. ($5.04 to $6) per week; stove attendants, 28s. to 30s. ($6.72 to $7.20); laborers, 25s. to 27s. ($6 to $6.48) per week. The city furnishes the uniforms.

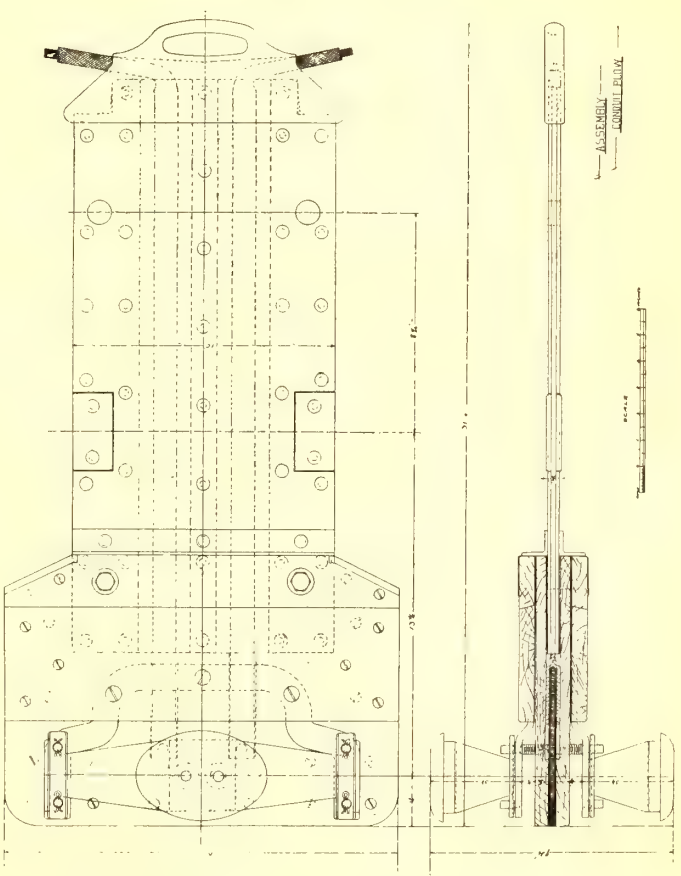


Plans of the London United Tramways Company

The most important tramway work now being projected in London is that of the London United Tramways Company, occupying the district extending from Hammersmith to Hounslow and Hamton Wick on the southern boundary of the city, and from the Central London Railway terminus at Shepard's Bush and Hanwell to Uxbridge on the north. With the junction line uniting these tramways this system amounts to about 75 miles of track, covering 39 miles of street. Of this about 27 miles are in operation by horses.



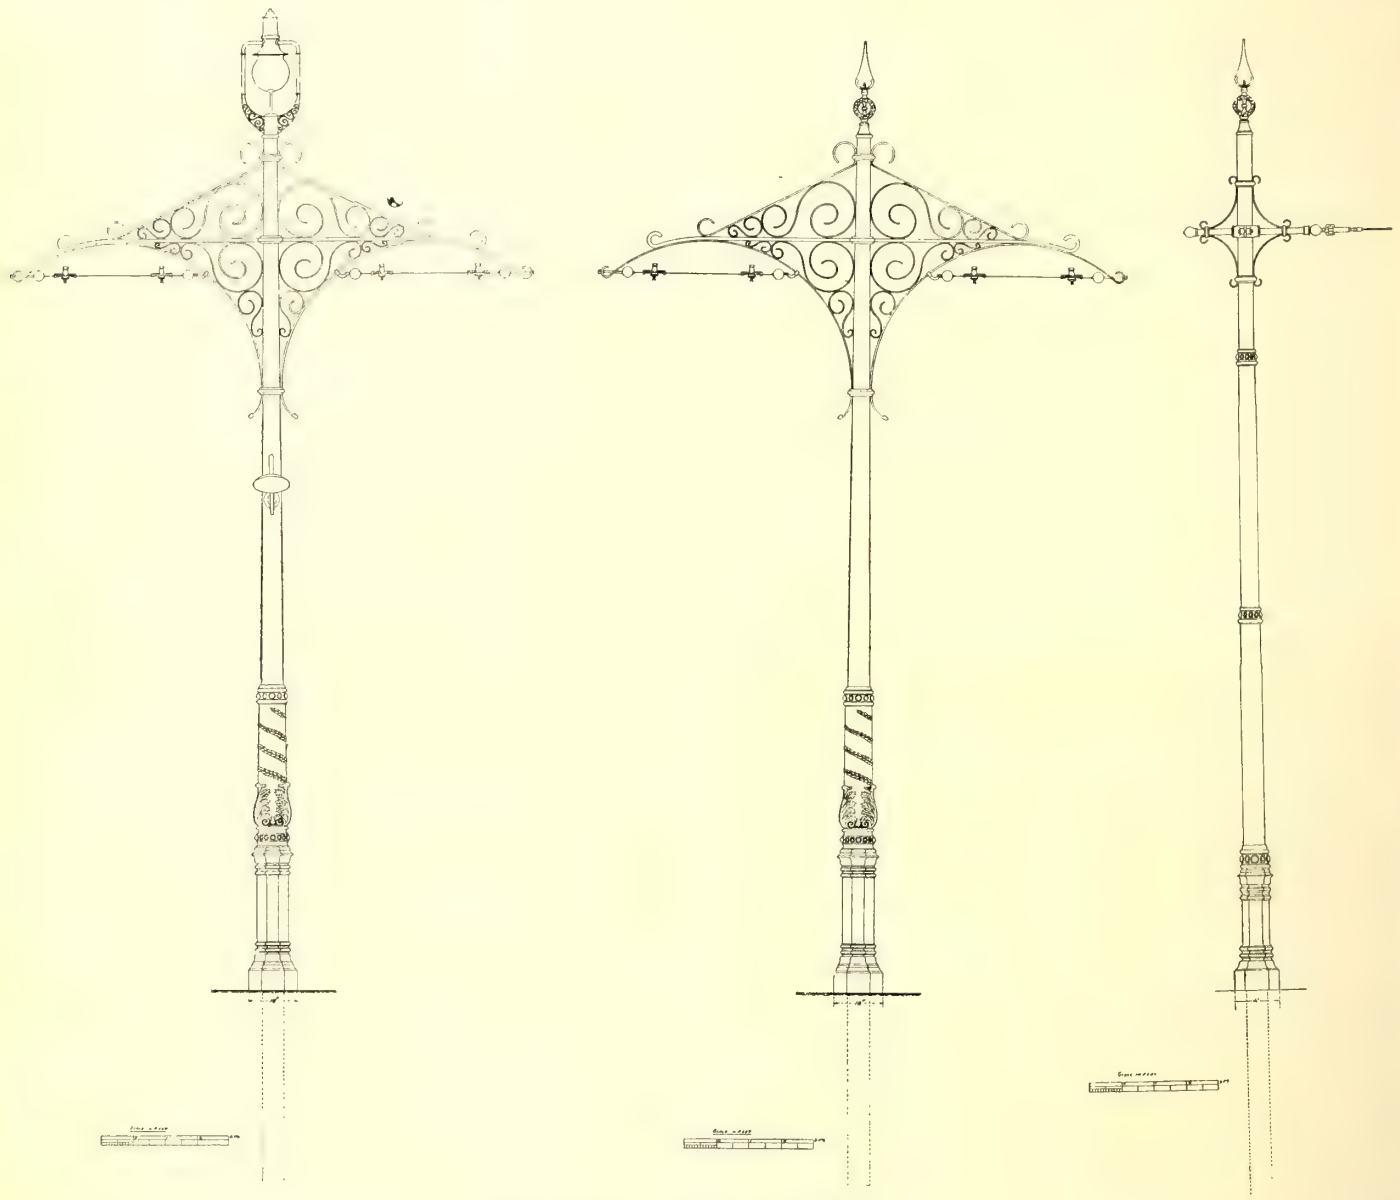
SECTIONS OF CONDUIT CONSTRUCTION



The plans of the company for electrical construction were described fully in an article in the Street Railway Journal for July, by J. Clifton Robinson, managing director of the company. Both the trolley and underground systems will be used. The former will cover about 20 miles, and is now under construction. It will be located, of course, in the suburban portion of the route. The road will be operated on the three-wire system, and two trolley wires will be carried over each track, making a complete metallic return. The two inside wires will be inter-connected, and will form the neutral pole of the system. The

PLAN, SECTION AND SIDE ELEVATION OF CAR

PLAN OF CONDUIT CONSTRUCTION



SIDE ELEVATION AND CROSS SECTION OF PLOW

overhead wires will be divided into half-mile sections, and, in order to meet the Board of Trade requirements, each 1½ miles of the line will be supplied by an independent feeder running direct to the power station. The neutral return will also be reinforced for each section of a mile and a half by a separate feeder.

The power station will be at High Road, Chiswick, and will have a capacity of 5000 h.p. The engine room will contain at present three 750-h.p. engines, each driving a 500-kw., three-phase 500-volt generator, with a frequency of 25 cycles per second. The section farthest from the center of the line, about 8 miles distant, will be operated by a sub-station, to which the alternating current will be carried by underground feeders. In this station will be seven transformers of 150 kw. each, and four rotary converters of 200 kw. each, which will deliver the current to the line at 550 volts. The converters will be electrically connected, so as to act both as converters and balancers. In case one side of the three-wire system is overloaded the converter will act on the opposite side as a motor, and thus assist the overloaded machine. The line poles will be extremely tasteful in design. As shown in the accompanying engravings, they will be of three types, one a span wire pole of three sizes, measuring respectively 16 ins., 18 ins. and 20 ins. at the base; and two bracket poles, one surmounted by an arc light.

The underground conduit system will be similar in general features to that used in New York, with cast iron yokes every 5 ft., and concrete sub-struction. Hand-holes will be located every 15 ft. and man-holes about every 150 ft., depending upon local conditions. The slots will be ¾ in. in width, and the conductors will be T irons, held in depending porcelain insulators similar to those employed in New York and Washington. The plow will provide a sliding contact by means of shoes held against the contact rails by spring pressure.

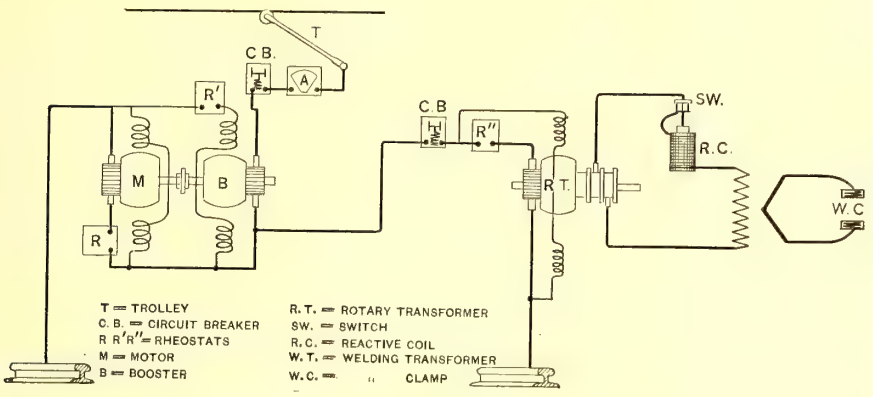
The cars will be double decked, mounted on maximum traction trucks. They will be 33 ft. 4 ins. over all, with length of body outside 21 ft. 11½ ins., and length of body inside 21 ft. 4 ins. The width of the car at belt rails will be 6 ft. 6 ins., and the height from the track to the top of the roof, when the car is empty, 9 ft. 9½ ins. From the track to the top of the trolley standard the height will be 15 ft. 2 ins. The cars will be equipped with cross-seats on the top and longitudinal seats inside. H. F. Parshall is consulting engineer for the company.

STANDARD BRACKET AND SPAN POLES

The economic and social results which are to follow from the development of the electrical street railway are only second in importance to those which have followed from the development of the steam railroad. From address at the Boston Convention, 1898.

Electric Rail Welding in Buffalo

The work of electric welding 7500 rail bonds in Buffalo for the International Traction Company, referred to in a recent issue, is now well under way, and about 2500 joints have been made up to date. The method employed is the improved system of the Lorain Steel Company, described fully in an article by Mr. Kleinschmidt in the May issue of the STREET RAILWAY JOURNAL.



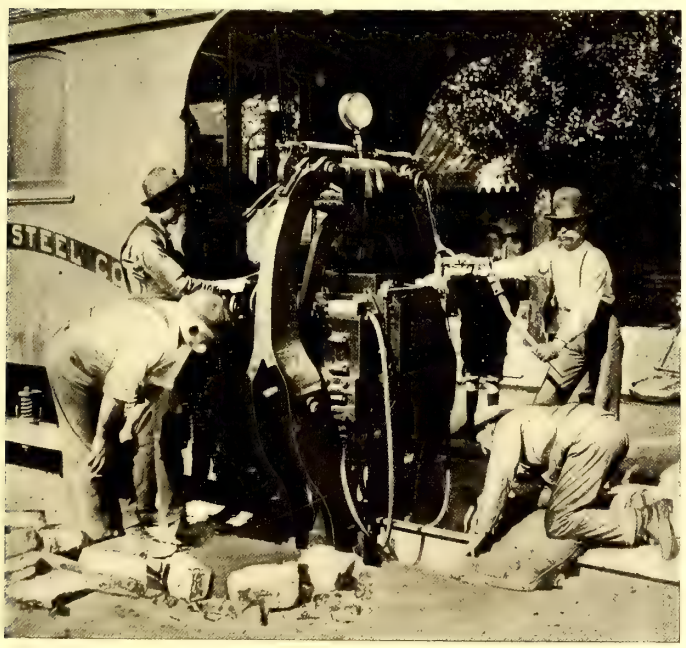


DIAGRAM OF CONNECTIONS FOR RAIL WELDER

The outfit in use in Buffalo consists of five cars, one of which is the welding car, the second a rotary transformer car, the third the booster or motor car, the fourth car is a sand and ballast car, which goes in advance of this train and prepares the joint for welding, and the fifth car, which

FRONT VIEW OF RAIL WELDING MACHINE

is equipped with a motor and emery wheels for grinding down any inequalities of the joints.

The connections of the apparatus used are shown in the accompanying diagram. The welding transformer primarily is run at 300 volts, and the voltage at the welding plant terminals is from 5 to 7 volts. The current used for the welding runs as high as 25,000 amperes. The use of the rheostat is to enable the attendant to raise the voltage of the machine by any amount desired to compensate for any lack of line voltage.

Method of Checking Fares on Interurban Railways

A most complete system of auditing railroad tickets, cash fare receipts, checks, etc., is employed by the Dayton & Western Traction Company. It is the invention of J. W. Lutz, cashier of the company, and seems to be well adapted to long electric lines, where a variety of fares is employed. It affords a complete check on conductors and agents, as by it no ticket can be a total loss to the company. Duplicates turned into the office do not need to be counted and placed consecutively, and no other record than the checking described is used.

A sheet of paper 17 ins. x 24 ins. is printed or stamped with sixty tables, each similar to that shown above.

FORM OF TICKET

These are numbered consecutively, and as each table represents 100 tickets, a sheet of the size mentioned represents 6000 tickets, or numbers. If 21,001 is the number of the ticket first to be checked then the first table would, of course, be numbered 210(00) and the sheet would then be ready for checking all tickets between 21,001 and 27,000

inclusive. It will also be noticed that the table has a blank line at the top. On this is entered the name of the conductor or agent to whom the 100 tickets represented by the table are issued. The Dayton & Western Traction Company has adopted a rule that where a ticket is not accounted for within a certain length of time, the person to whom it was issued pays for it just as if he had collected the fare for it. This makes conductors careful, cautious and accurate.

The form of ticket below shows the company's standard form of cash fare receipt and return trip tickets. It consists of two parts, as shown. Where a cash fare is paid, the points between which the ticket is issued are punched, together with the charge for a single fare. The left hand half is then given to the passenger and the right hand half is turned in to the company, hence it can never be used. Where a round trip ticket is purchased, the points between which the ticket is issued and price paid are punched, but the right hand half is given the passenger and the left hand half returned to the office. The portion given to the passenger is then good for a return trip, and is taken up by the conductor of the car by which the trip is made. Half fares are indicated by punching the space marked "half fare."

The auditing system is copyrighted, and the form of ticket shown has been patented by Mr. Lutz.

Electric Railway Construction in Buenos Ayres

The work on the construction of the Buenos Ayres & Belgrano Electric Tramway, which is being carried on under the instruction of Messrs. Kincaid, Waller & Manville, of London, is approaching completion. Six miles of this line are now open, and the financial results have been most satisfactory. Current is obtained from a French electric light company.

DOUBLE DECKED CARS AT BUENOS AYRES

Both single and double deck cars are used. They were supplied by Jackson & Sharp, The J. G. Brill Company and Barney & Smith, and are mounted on Peckham trucks.

The first engraving shows a view of one of these cars taken opposite the Hippodrome, where a long siding was installed to care for the extra traffic. As will be seen, double bracket poles are used, the bracket on one side extending across two tracks. The second engraving shows a car at Portones.

It is reported that the Westinghouse Company has received a large order for electric railway apparatus to be used at the Paris Exposition in 1900.

A German Definition of a Railroad

During a recent law suit in Germany for injuries sustained through a railroad accident the question arose as to the true definition of a railroad. The highest German court, the Imperial Court at Leipzig, has given the following:

"A railroad is an enterprise whose function is to transport persons and merchandise over comparatively long distances upon a metallic roadway, which, in view of its peculiar construction and ease of operation, can transfer great weights and permit a high rate of speed during this transportation by employing natural forces (such as steam, electricity, animal and human muscular power), including in some instances the weight of the operating agent, and, under certain circumstances, is able to render considerable service, as well as be dangerous to human life and health."

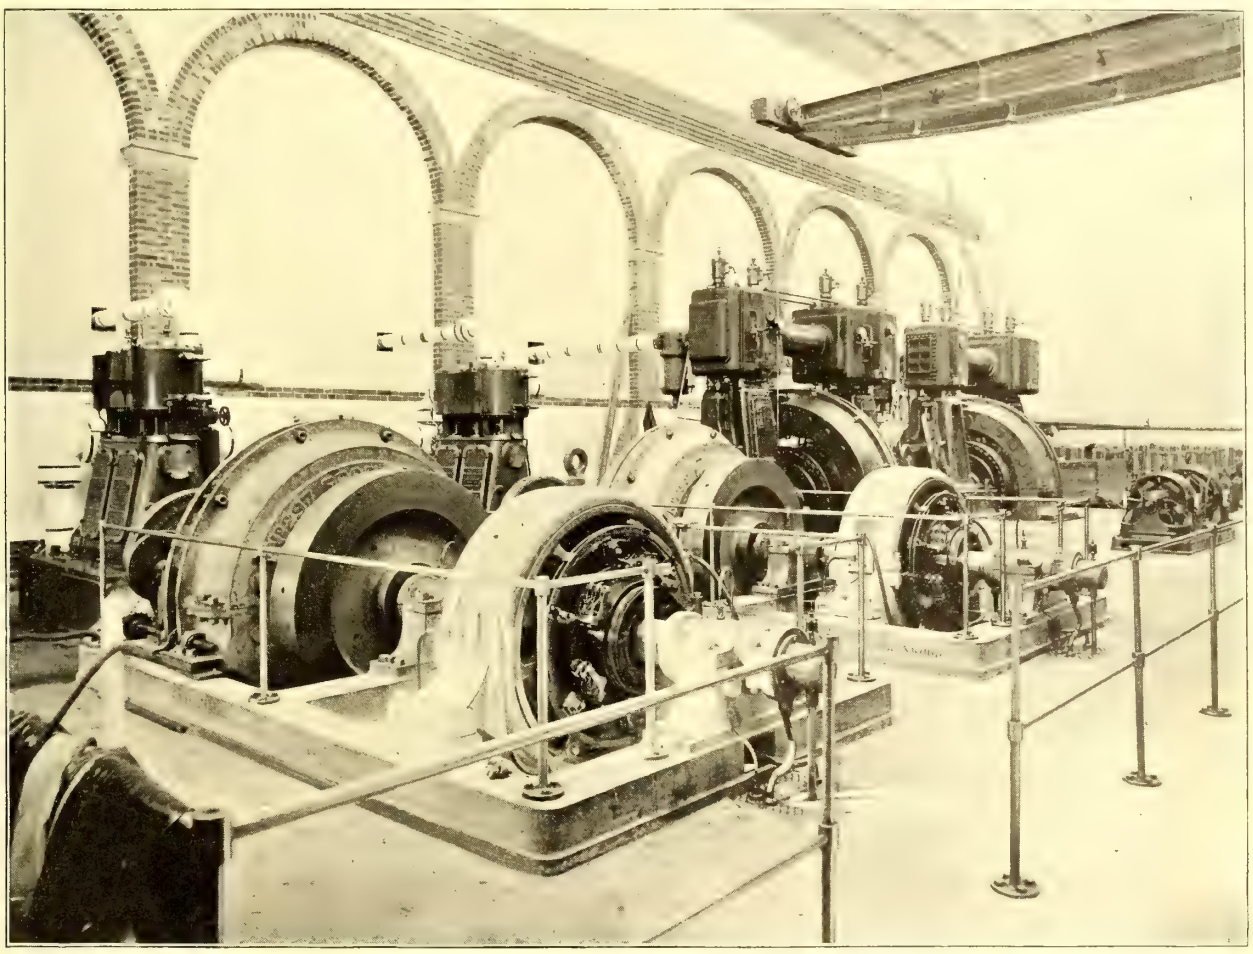
Stiffening a Stairway

Where room is at a premium, as it frequently is in car shops and barns, the spiral stairway is an economizer of space, but the problem arises how to make safe the railing necessary around such stair openings. A cheap and easily applied method is to put up a light fence of $\frac{7}{8}$-in. sheathing, using a 2-in. x 4-in. rail near the top of the boarding, and, perhaps a light cap on top, the bottom of the sheathing to be nailed to the floor with a quarter-round one on both sides. To strengthen this light construction, run a 1-in. pipe around inside the sheathing, the pipe being either put together with elbows, or, what is better, the corners bent in the smith's forge. Holes are drilled even 12 ins. or 15 ins., and common wood screws or carriage bolts used for fastening the pipe to the 2-in. x 4-in. rail above mentioned. In most cases, it will not be necessary to fasten the pipe to the wall or floor, as it stiffens the woodwork sufficiently without such fastening. But if desirable, the pipe may be fastened to the wall by means of a flange screwed directly to the end of the pipe or to the floor by means of an inserted T and a drop leg thereto.

The method of lubrication largely affects the life of brasses. After long tests with various lubricants the writer has discontinued entirely the use of grease on armature brasses, and in most cases on axle brasses, a good grade of engine oil, supplied through wicks, being more satisfactory and economical. From paper at the Boston Convention, 1898.

Plymouth Electric Tramways

(By Our Special Correspondent.)



Plymouth, the first town in England to be incorporated by act of Parliament (so long ago as Nov. 12, 1439) is among the first of the great towns in England to adopt electric traction on its corporation tramways. The system will, I think, compare favorably with any now in operation.

Plymouth has an interesting municipal history. It possesses the oldest municipal water works, authorized by an act passed in 1585 through the influence of Sir Francis Drake, the celebrated navigator, who was then mayor. In 1892 the corporation acquired the tramways and in February, 1896, unanimously appointed J. Hall Rider, A. M. Inst. C. E., etc., its electrical engineer. Mr. Rider, upon his arrival at Plymouth, was at once called upon to prepare plans and specifications for the proposed electric supply works, and these, the first works in this country, designed primarily for running the tramways, combined with the lighting of the town, are now completed.

They have been built on corporation land, with rocky subsoil, at Prince Rock on the Cattewater, as the estuary of the river Plym is called, and immediately adjoining will be constructed a refuse destructor by contract with Goddard, Massey & Warner, who are guaranteeing 280 i.h.p. per hour. This destructor will be used for the tramways and the electricity committee will pay the works committee (who are responsible for the destructor) at the rate of ¼d. per kw. hour of electric energy produced. This arrangement will mean economy to both committees, as it will bring some £1560 to the credit of the destructor and is a much cheaper rate for the electricity committee than could be secured by independent action.

The accompanying map shows the existing electric lines in solid black, horse lines, authorized for conversion to electricity, in dashed lines, and proposed new electric extensions in dotted lines. Horse cars have been running for some time on the electrically equipped route from the Theatre Royal to Prince Rock. The length of this section is 3 1-10 miles of single track. The lines are double nearly all the way, and were laid by the corporation. The rails are grooved girder section, 92 lbs. to the yard and 30 ft. in length. Probably 60-ft. rails will be used in future extensions. Each joint is bonded with three No. 000 Chicago bonds 30 ins. long. The tests of the conductivity have given most satisfactory results.

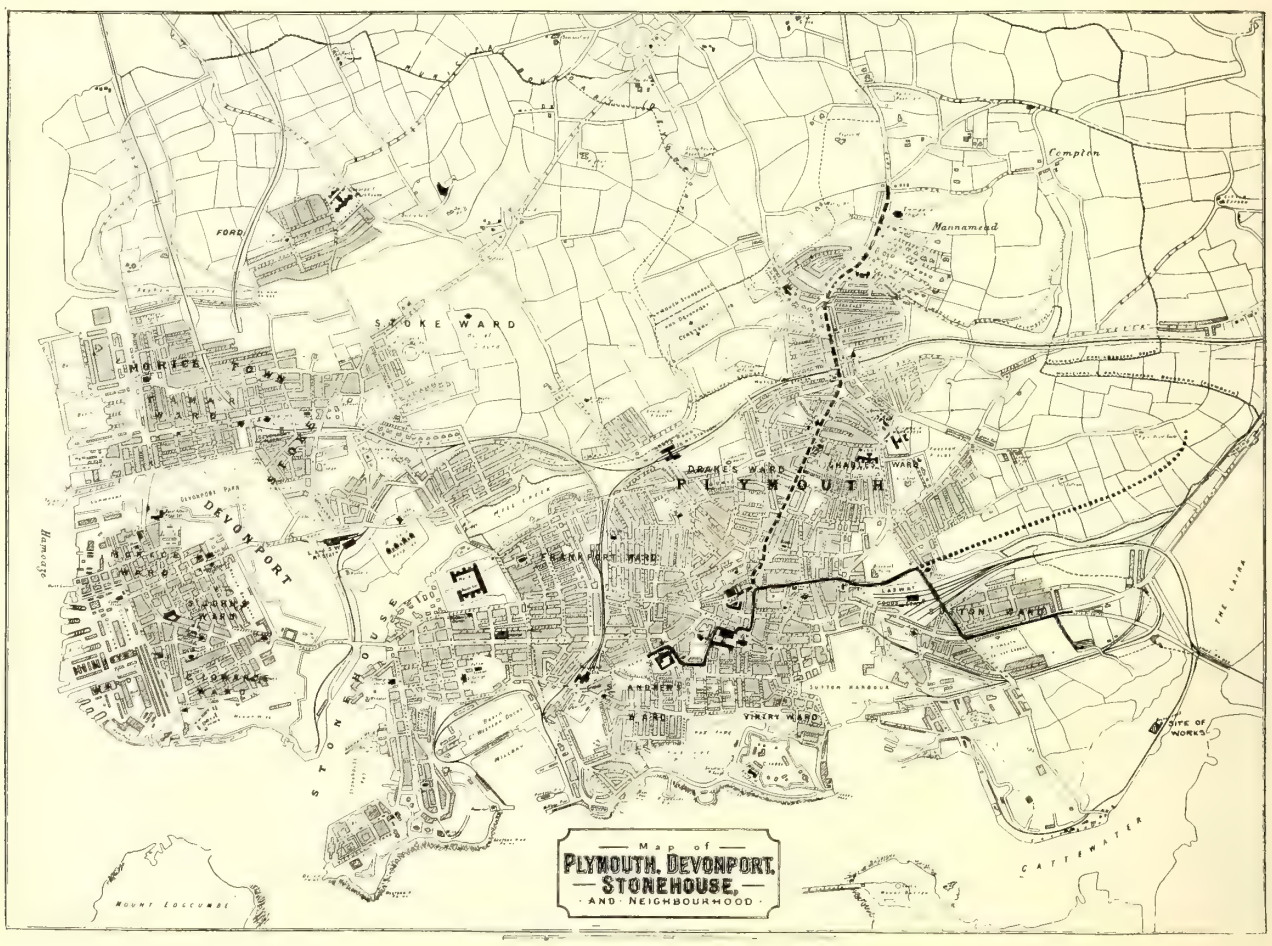
The electrical equipment of the tramways was undertaken by the Westinghouse Company, who sublet the overhead construction to R. W. Blackwell & Co. The details were designed by Mr. Rider to suit the character of the road, and no fewer than five different methods of carrying the wires have been employed, viz: (1.) Side bracket arm, carrying both wires on one side of bracket. (2.) Side bracket arms on both sides of track, each carrying one wire. (3.) Span wire from pole to pole. (4.) Span wire from pole on one side of rosette fixed to building on other, and (5) span wire from rosette to rosette.

INTERIOR OF POWER STATION, PLYMOUTH, ENGLAND

Owing to the great number of telegraph and telephone wires, guard wires will be put up over more than half the route. This rather detracts from the exceptionally neat and workmanlike appearance of the overhead construction, which is helped, in no small degree, by the handsome bracket arms, the wrought iron scroll work of which is most effective. This scroll work was designed by E. G. Okell, Mr. Rider's chief assistant, who has been associated with him throughout the designing and construction of the works. He, Mr. Rider and W. T. Tester, the con-

tractor's resident engineer, are to be warmly congratulated on the successful results of their combined efforts.

The poles are three sectional, with S. S. S. joints, of 7 ins., 6 ins. and 5 ins. outside diameter, with heavier poles of 8 ins., 7 ins. and 6 ins. diameter at curves. There are a few single tube poles, 8 ins. in diameter for half way and then tapering to 6 ins. at top. These, as well as a large proportion of the sectional poles, were supplied by Russell & Sons, of Wednesbury. Arc lamps are fixed in a number of streets on the tops of alternate poles and, where possible, on alternate sides of streets, and a fiddle-bow suspension, between the ears holding the wires, has been fitted to take off the oscillation from the lamps.



The line is divided into ½-mile sections, according to Board of Trade requirements, and insulated in the usual manner. Of the section boxes two have been very neatly disposed of, by being built into the walls of corporation buildings. They contain four switch fuses, lightning arrestor, telephone, wire terminals, etc.

The overhead equipment, the permanent way and the cars are provided by the tramways committee, while the electricity committee is responsible for all the underground cables and supplies the current to the section boxes, just as would be done in the case of a private consumer, charging the tramway committee 3½d. per unit up to 150,000 units, beyond which figure there will be a reduction in price. It is estimated that the price will be reduced to 2.3d. per unit as soon as contemplated extensions are completed, when some 600,000 units will probably be required.

At present there are six motor cars to seat twenty inside and twenty-two outside. They are mounted on Peckham standard cantilever extension trucks with 30-in. wheels, 3 ft. 6 ins gage, and a 5 ft. 6 ins. wheel base. The car bodies were built by Milnes & Company, of Birkenhead, and are 14 ft. long, 24 ft. 6 ins. over platforms, and 6 ft. wide. Each car is fitted with two Westinghouse No. 46 motors, giving 1000 lbs. tractive effort at 8 miles an hour. The cars are housed in a temporary car shed near the Prince Rock terminus, which will hold, in addition to the six motors cars, six trailers. These will be converted from the best of the horse cars now in use.

The controllers are of the Westinghouse series parallel type with a graded brake, and perfect control is kept over the car by putting the two motors in parallel and by connecting them by a variable resistance, if necessary, to the extent of short circuiting the motors. This brake has been working most satisfactorily throughout the trial trips.

The trolley is of the Blackwell side acting swiveling type. The standard, 6 ft. 6 ins. high, is placed in the center of the roof of cars, so that the arm can reach equally on either side. The arm is 15 ft. long.

MAP SHOWING PLYMOUTH ELECTRIC TRAMWAY SYSTEM

Sanction has been given for electrically equipping the line from the Market Place to Compton. This route will take 2¾ miles of single track and will tap the residential district of Mannamead. Six more motor cars will be required for this section, and another six for the section from Theatre Royal to Hyde Park at Mutley. The cars on this route will run from the theatre over the Prince Rock tracks as far as the market and then run up the Compton line, turning off to the terminus at Hyde Park. There will probably be a sub-station with a large battery of accumulator cells for the Compton route. The corporation is also applying for power to the Board of Trade to construct 2 miles of additional lines to the eastward of the town. This district is growing very rapidly and is peopled by the working classes.

The power station contains a lighting plant, distributing

an alternating current at 2000 volts pressure to sub-stations and a 500-volt to 550-volt continuous current tramway plant. In order to avoid having to run the engines at a light load during the day, a special combination plant has been designed by Mr. Rider. There are two sets in use; each consists of a Belliss high speed compound engine of 150 i.h.p. running at 275 r.p.m., direct coupled to a Ferranti alternator of 100 kw. and also to a Westinghouse generator of 100 kw. The engine is therefore capable of driving either machine at full load or both at half load. Between the engine and the machines is a special shaft coupling, so that the engine can be disengaged when required. A battery of 260 Tudor cells is kept in parallel with the generator. During the day the engine can be kept at practically full load, the alternator supplying what small amount of current is required for lighting, and the generator driving the cars. The battery, in parallel with the generator, takes up the inequalities of the tramway load, any current required above the output of the generator being supplied by the accumulators, and all under being taken in by the accumulator in the form of a charge. In this way a practically constant load can be kept on the generator and therefore on the engine, and the cells are continually charging and discharging according to the demands of the line.

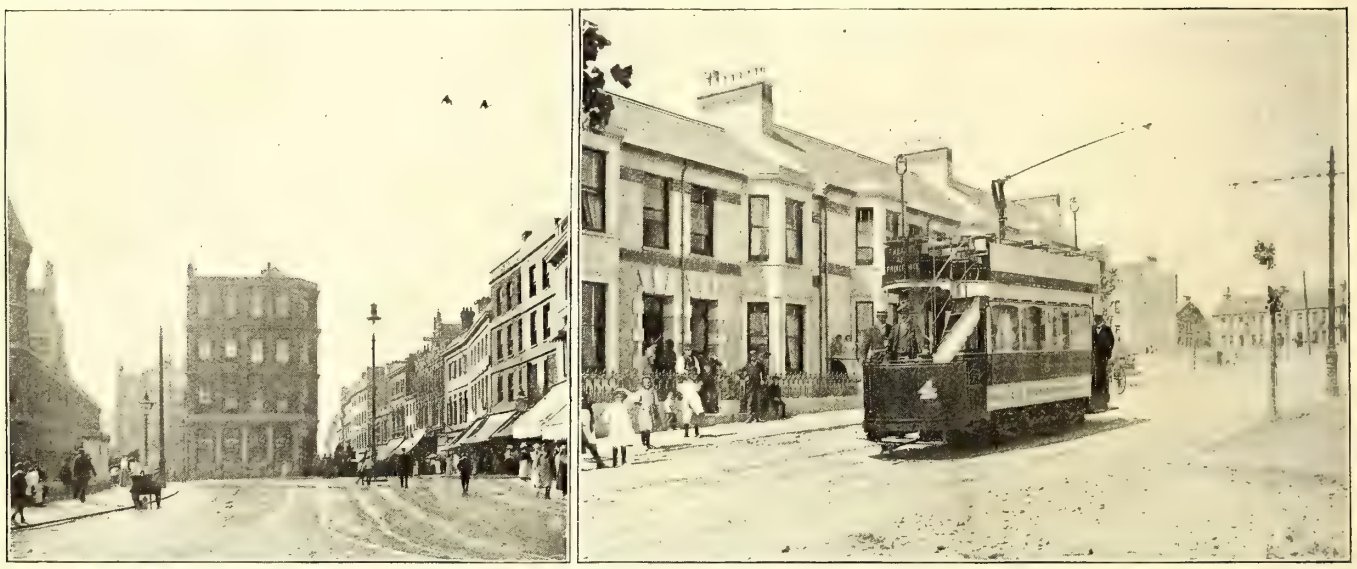
As the lighting load increases during the evening, the load is gradually taken off the generator by the accumulator, leaving the engine free to drive the alternator at full load for the lighting. After midnight, when the cars have ceased running, the generator is driven at full load for charging the battery until 6 o'clock in the morning when the cars commence running.

SPAN POLE AND ROSETTE CONSTRUCTION

The use of the clutch enables the generator and alternator to be used independently of the engine when required; thus on Sundays, when the cars are not running, the generator will be run as a motor from the accumulator, driving the alternator for what lighting load there may be. Similarly the alternator can be run as a synchronous motor from either of the other alternators in the station and the generator used either for charging the battery or for tramway work with the battery in parallel.

It is not proposed to continue this type of combination right through the station when additional tramway machinery is put down, its great use being for a day load plant.

BRACKET POLE CONSTRUCTION



The battery consists of 260 Tudor cells of 600 amp. hours capacity; maximum discharge rate 200 amps. The battery is maintained by the Tudor Company under guarantee for ten years at a rate of 5 per cent on first cost. The terms of the contract are that at any time within twelve hours of being fully charged the battery must give its full specified capacity of 600 amp. hours without the voltage per cell falling below 1.85 volts. The rest of the plant comprises two 200-kw. Ferranti alternators for lighting, driven at 250 r.p.m. and a 20-kw. booster, motor driven and used in series with the generator for charging the accumulator so that the bus bar pressure need not be raised. The booster generator is compound wound so that the current can be sent round the fields if it is desired to use the booster when the cells are being discharged. When the line current is equal to the output of the generator the two windings will neutralize each other and the booster will give no pressure. Then the battery will neither charge nor discharge. When the line current is less than the output, the shunt winding will predominate and the booster pressure will be in the right direction for charging the cells. When the line current is greater than the output, the series winding will change the polarity of the booster so that it will add a pressure to the battery circuit and thus help it to discharge.

The probable additions to the plant will include a steam driven generator of from 450 kw. to 500 kw.

All the auxiliary plant, stoker gear, feed pumps are electrically driven by E. C. C. motors.

The three Lancashire boilers were supplied by J. Musgrave & Sons, of Bolton, and are rated at 350 h.p. each. One supplies the two Bellis engines and the other two the two Ferranti alternators. Welsh coal is brought by steamer to the wharf alongside and is distributed by a Vicars stoker.

There are three switchboards, one of the Westinghouse tramway type, one Ferranti type, and the third a Ferranti rectifier board. All of the regulating resistances are fixed in the room immediately under the switchboard recess. The cables were supplied by the British Insulated Wire Company and laid by the corporation.

SCENES IN PLYMOUTH, SHOWING ELECTRIC TRAMWAY

At present the tramways only pay expenses, the cost of 10d. per car mile preventing the formation of a sinking fund. With electric power the expenses are calculated at 5d. per car mile, and as owing to the increased speed a much more frequent service of cars will be run; it is not unreasonable to expect a handsome profit.

The Spree River Tunnel

The tunnel under the Spree River, intended for street railway traffic between Stralau and Treptow, near Berlin, has been completed and will be opened for public service in a very short time. The construction of this tunnel illustrates the increasing tendency in late years of the German corporations to follow American practice by selecting the shortest route, regardless of cost, and thereby meeting competition successfully. For a long time the park at Treptow, on the banks of the Spree, has been a much frequented resort for the residents of Berlin, because of its proximity to the city. This tunnel gives to the thickly populated section at the Silesian railway depot a new route by which the park may be reached in a shorter time. The most interesting part of the construction of this tunnel is the fact that it is the first that has ever been built curving under a river, by the Greathead system. To still further add to the complexity of construction quicksand was encountered along its entire length.

Its dimensions are as follows:

It is 453 m. long, and crosses the river nearly at right angles, the river being 200 m. wide at this point. Its lowest point is 10.7 m. below the average water level, the average depth of the river being 3.3 m., and the diameter of the tunnel 4 m.; this leaves 3.4 m. of solid earth above the tunnel.

The grade directly under the river is 1:600, while that near the mouths is 1:20. The total length, including the masonry at both ends, is 609 m.

A few details of construction may prove interesting:

The iron shell is composed of separate rings 650 mm. long, joined together by stiffening ribs 15 mm. in thickness. Each ring is composed of nine wrought iron flanged sections. The ribs project 50 mm. outside of the shell, and 15 mm. inside, the outer projections being utilized to hold a cement covering, while the inner serve for caulking, so as to insure water-tight joints. The cement is forced through holes in the shell, which are afterwards closed with iron or wooden plugs.

As extensive experiments before the construction of the tunnel and previous practical experience had proven that plates only 10 mm. in thickness were sufficiently strong, a great saving in cost was thereby effected.

To prevent the rusting of the interior and the exterior of the iron shell coatings of cement, from 80 to 100 mm. thick, were applied.

The tracks on the bottom of the tunnel, which are of the standard gage, are embedded in beton. A ditch collects all water, which is pumped out by means of an electrically driven pump.

The header used during the construction of the tunnel is patented, and is composed of an iron tube, the cutting end of which is beveled at an angle of 30 degs. to the base of the tunnel. A partition divides it into two compartments, the rear one always projecting over the forward end of the tunnel.

The breast wall of the tube is provided with openings, through which the sand is removed, also ball and socket stuffing boxes, through which drills may be passed to break up hard obstructions.

The header is moved forward by means of hydraulic jacks placed against the partition in the tube, and the end of the last section of the tunnel put in place. The total pressure amounts to 900 tons. The downward curve given to the tunnel is effected by an unequal location of jacks, in other words, by putting more pressure on the top than on the bottom of the partition in the tube.

Owing to the great difficulties encountered two and one-half years were occupied in the completion of this project. The daily advancement at the beginning amounted to 0.7m. to 1.00 m.; on some days a progress of 2 m. was made, and the general average being 1.5 m. per day.

LEGAL NOTES AND COMMENTS*

EDITED BY J. ASPINWALL HODGE, JR., OF THE NEW YORK BAR

CHARTERS, ORDINANCES, FRANCHISES, ETC.

ILLINOIS.—Removal of Causes—Electric Railroads—Condemnation of Land—Highways—Price—Consent of County Board—Instructions.

1. Two of several tenants in common, who are non-residents, and who have been joined with their resident co-tenants and the resident mortgagee of the interest of one of them, in condemnation proceedings, are not entitled to a removal of the proceedings to the United States Circuit Court when the aggregate of their claims exceeds the sum of $2,000, but the amount of their separate claims is less than that amount.

2. In condemnation proceedings for an electric railroad, evidence that the secretary of the company, seeking to condemn the land, called on one of several tenants in common, and made him an offer for the whole tract; that the tenant then said he would have to see his co-tenants, who were his sisters, about the matter, and requested two or three days to consider the matter; that at the end of such time the secretary called again, and that the offer was refused,—shows an inability to agree on a price for the tenant's separate share as well as that of the whole tract.

3. The County Board, and not the Township Commissioners of Highways, is the proper body from which to obtain consent to the construction of an electric railway on a public highway over which a turnpike company has an easement.

4. The giving of an instruction in condemnation proceedings, in regard to a matter not in issue, and which could not, one way or the other, affect the amount of compensation defendants were entitled to, is not error.

5. Refusal to give an instruction which leaves to the jury the construction of a deed is not error.

6. In condemnation proceedings by an electric railroad company against the owners of the fee, to secure the right to operate its line on a public highway over which a turnpike company has an easement, an instruction that, if the jury believed from the evidence that the turnpike company had abandoned that part of the road on which the railroad was to be constructed, the jury might take that fact into consideration, is properly refused, as it would still be a highway, and the amount of defendant's damages would not be affected. (Trotler vs. St. Louis B. & S. Ry. Co., 54 N. E. Rep., 487.)

MICHIGAN.—Municipal Corporations—Power to Operate Street Railroads—Constitutional Limitations—Internal Improvements.

1. Under Const. art. 14, sec. 9, providing that "the State shall not be a party to or interested in any work of internal improvement, nor engaged in carrying on any such work," works of internal improvement, which the State itself is prohibited from undertaking, it cannot authorize municipalities to undertake or become interested in.

2. The street railroads of Detroit, comprising over 140 miles of track, and valued, with their equipment, at from five to twenty million dollars, are works of internal improvement.

3. The act of the Legislature of Michigan authorizing the creation by the Common Council of the City of Detroit of a commission of three men, to be known as the "Detroit Street Railway Commission," and conferring on such commission, when appointed, the power, in their discretion, to purchase, lease, or otherwise acquire by conveyances to the city, any street railroad wholly or partly within the city, together with its property, rights, and privileges, and to extend and operate the same in behalf of the city by the carriage of passengers and freight for hire, is in violation of the provision of the State constitution prohibiting the State from becoming interested in any work of internal improvement, and is void. (Attorney General vs. Pingree et al., 79 N. W. Rep., 814.)

MISSOURI.—Authority to Amend Charter—Extension of Lines—Parallel Law—Repeal—Quo Warranto.

1. Rev. St. 1889, sec. 2779, authorizing a corporation to "extend its business to any other purposes authorized by this article," is not merely a permission to a corporation, organized for one of the eleven purposes allowed by sec. 2771, to extend its business so as to embrace another of the eleven purposes, but authorizes a street car company, whose termini were fixed by the original incorporation, to amend its charter so as to extend the original termini, and thereby carry the public a greater distance for the same fare, or so as to include the right to buy or lease a road already constructed.

2. Where a street railway company has, from time to time, by municipal authority, extended its lines beyond the termini stated in its original charter, and such grants are greater in extent and longer in mileage than the one challenged in the case at bar, but no one has ever questioned their legality, and relator expressly disclaims any desire to have the company ousted therefrom, the writ of quo warranto will be refused.

3. Act Jan. 16, 1860 ("Third Parallel Law"), provides that no street railroad shall hereafter be constructed in the city of St. Louis nearer to a parallel line than the third parallel street from any road now constructed, or which may thereafter be constructed, except the roads hereinbefore mentioned. At that time the Legislature alone had power to legislate as to the city of St. Louis. Acts 1865-66, pp. 279-287, amended the St. Louis charter, and gave the city sole power to grant the right "to construct street railroads in any street of said city, and to regulate and control the same and the use thereof." Const. 1875 expressely prohibited the Legislature from granting the right to construct or operate or transfer a street railway in any city of the State, without its consent, and gave the city of St. Louis the power to adopt a charter which should supersede all prior charters. The charter so adopted by the city gave it the sole right to grant the right to construct street railways and to regulate street car companies. *Held*, that Act 1860 was repealed by implication by Act 1866 and Const. 1875. (State ex rel. Crow, Attorney General vs. Lindell Ry. Co., 52 S. W. Rep., 248.)

NEW JERSEY.—Abandonment of Operation—Excuse for Non-performance—Mandamus—Parties.

1. A street railway company incorporated under the laws of this State, and the route of its road, and the location of its tracks, established by an ordinance of the municipality in the streets of which the company is to operate its road, such ordinance being accepted by such company, and its tracks laid in accordance therewith, and the road constructed and in operation, cannot, at its mere will and discretion, cease and abandon the operation thereof, or any portion thereof. It becomes the duty of the railway company, in the exercise of its rights, privileges, and franchises, for the benefit of the public to maintain and operate its road according to the terms of the ordinance, and in compliance with statutes which confer upon the company such rights, privileges and franchises.

2. An implied condition attaches itself to the grant of the franchise that it be held for public benefit, and the duty upon the railway company is to exercise it for such purpose, and, as a public agent, it cannot escape this duty.

3. The company, duly incorporated, which has the ownership of, and is in possession and control of, such street railway, its appliances and property, whether under a lease of or by sale from the original or other company incorporated to construct and operate such railway, or by sale under a decree of the Court of Chancery of this State upon foreclosure under the statute of the State concerning the sale of the property and franchises of certain corporations (P. L. 1897, p. 229, c. 127), has conferred upon it all the corporate rights, liberties, privileges and franchises of such original or other company, and upon it rests the same burden and duty to maintain and operate such street railway under the statutes and the ordinance of the municipality as was imposed upon the original company.

4. The fact that the located route of the railway is laid across a bridge over a stream, the construction, maintenance and control of which bridge is in the Board of Chosen Freeholders, which will not permit the tracks to be laid thereon unless upon proper and reasonable regulations for the safety of the bridge for the traveling public, furnishes no excuse why the road should not be operated upon its route through the streets of the municipality lying upon either side of such bridge. The acceptance of the ordinance being apart from the control of such bridge by the Board of Chosen Freeholders, and having no relation to it, or to its use, and there being an agreement between the railway company and the chosen freeholders in relation to the use of such bridge, the court will not enter upon the consideration of the reasons why the company has not performed such agreement, in order to excuse the company from the performance of its duty towards the municipality in the operation of its road.

5. Mandamus is the proper remedy to compel such street railway company to perform the duty of maintaining and operating such railway for the benefit of the public. The public duty imposed upon the company is always active, potential and imperative, and must be executed until lawfully surrendered, suspended or abandoned by the legally expressed consent of the State, and the performance of this duty can be lawfully enforced by mandamus.

6. The municipality in the streets of which the railway is located by the ordinance is a proper relator in a proceeding by mandamus

* Communications relating to this department may be addressed to the Editors, Johnston Building, 30 Broad Street, New York.

to enforce the duties of the company toward the public. (State ex rel. City of Bridgeton vs. Bridgeton & M. Traction Co., 43 Atl. Rep., 715.)

NEW YORK.—1. Electric Street Railway—Grant of Certificate.—The grant of a right to build a street surface elevated railroad, connecting several localities of considerable importance, between which there is no direct railroad communication, in territory for the most part within the city of New York, is proper, though the proposed road would in some instances nearly parallel a steam railroad, where it would furnish means of local transportation which were not, and could not well be, furnished by such steam railroad.

2. Same—Grant.—Under Railroad Law, sec. 59, authorizing the Board of Railroad Commissioners, before granting a certificate for the construction of the road, to permit errors, omissions, or defects to be supplied and corrected, a change in the route of an electric railway, not affecting substantially its character, and made to obviate objections of the local authorities, is such a defect as could be corrected under the powers given under said section; and such change could be disregarded or approved, if made after the filing of the articles, and before the application to the board. (People ex rel. Long Island Ry. Co. vs. Board of R. R. Com'rs of New York, 59 N. Y. Suppl., 144.)

OHIO.—Change of Venue—Suit Against Corporation—Constitutional Law—Sufficiency of Affidavit—Presumption of Credibility—Rule as to Evidence—Order Overruling Application—Error Waived.

1. Sec. 5033 of the Revised Statutes, which provides for a change of venue "when a corporation having more than fifty stockholders is a party in an action pending in any county in which the corporation keeps its principal office or transacts its principal business, if the opposite party make affidavit that he cannot, as he believes, have a fair and impartial trial in that county, and his application is sustained by the several affidavits of five credible persons residing in the county," is not in conflict with the State or Federal Constitution.

2. It is not necessary, to entitle the applicant to the benefit of the statute in a case for which it provides, that his affidavit shall state the grounds of his belief that he cannot have a fair and impartial trial in the county in which the action is pending, nor that the sustaining affiants shall state the grounds of their belief. It is sufficient that the affidavit of the applicant state that he cannot, "as he believes," have a fair and impartial trial in that county. And his application is "sustained," within the purview of the statute, when there is filed the several affidavits of five credible persons residing in the county, stating that they entertain the same belief. When so complied with, the statute is mandatory.

3. Unless the character of an affiant for truth is attacked, he will be presumed to be a credible person, and evidence in his support is not required nor admissible; but, if attacked, it becomes a question for the court to determine whether he is a credible person, and unless found to be so, the application may be denied.

4. Whether the action is one in which a corporation having more than fifty stockholders is a party, or is pending in the county where the corporation keeps its principal office or transacts its principal business, are questions for the determination of the court in which the application is made; and, if the statement of these facts in the affidavit is denied, the burden is on the applicant to establish them.

5. An order overruling an application for a change of venue is not an order made in a special proceeding, which may be made the foundation of an independent proceeding in error, but is properly reviewable on error prosecuted to the final judgment in the action. The error is not waived by proceeding to a trial of the action without objection by the applicant. (Snell vs. Cincinnati St. Ry Co., 54 N. E. Rep., 270.)

UNITED STATES COURTS (OHIO)

1.—Constitutional Law—Impairment of Contracts—Ordinances Granting Street Railroad Franchises.

City ordinances making grants of franchises to street railroad companies on specified conditions, when accepted by the companies, constitute contracts, which cannot be annulled or amended except by consent of both parties, and which are protected from impairment by the fourteenth constitutional amendment.

2.—Equity Jurisdiction—Restraining Enforcement of Unconstitutional Ordinance.

A federal court of equity may grant relief by injunction against a city ordinance which impairs the contract rights of complainant or deprives him of his property without due process of law.

3.—Right of Municipality to Fix Rates of Fares.

The statutes of Ohio confer power upon municipalities to determine the conditions of the grant of a franchise to a street railroad company, including the rates of fare to be charged, but no power to thereafter prescribe rates of fare; and where the grant itself fixes the rate of fare a reserved right of regulation does not authorize the municipality to thereafter change it during the life of the grant.

4.—Constitutional Law—Impairment of Obligation of Contracts—Ordinance Changing Rates of Fare on Street Railroads.

A city, in granting franchises to two certain street railroad companies, fixed the rates of fare to be charged, reserving the right to increase or diminish such rates, as it might deem justifiable and expedient. Afterwards, by different ordinances, it granted additional franchises to each company, expiring with the original franchise, to build extensions, lay additional tracks, or to change the motive power. It imposed conditions to each of such additional grants, which were accepted by the respective companies, in the way of requiring street paving and repairing, or the furnishing of increased car service, to which the companies were not before subject. Such ordinances also made changes in the rates of fare by providing that but a single fare, at the rate then charged, should be charged for passage between any two points on either the original lines or their extensions, and by requiring the companies to sell tickets at a reduced rate. As to one of the companies, which, under the ordinance containing the reservation, had the right to, and did, charge two fares for passage over the entire length of its line, a subsequent ordinance granting it the right to lay a double track, and to maintain it during the life of its original franchise, required the carriage of passengers over the entire line for a single fare at the rate then charged, and such company was subsequently granted the right to change its motive power from horses to electricity, which it did, at a large expense. Each of said companies subsequently consolidated with a number of other companies, as to whom no power to change the rates of fare had been reserved by the city, their original lines, to which the reservation in regard to changing rates of fare applied, thus becoming parts of two several consolidated systems, each containing many miles of road, operated together. These consolidations were consented to by the city, the consents containing provisos, accepted by the consolidated companies, requiring transfers to be given, or through cars run, so that a single rate of fare or ticket at the rate then charged should entitle a passenger to ride over the lines of any two of the constituent companies, whereas they were before entitled to charge separate fares over each line. None of such legislation of the city subsequent to that granting the two original franchises mentioned contained any reservation of the right to make future changes in rates of fare. *Held*, that such subsequent legislation, and its acceptance by the companies, operated as a repeal of the provisions of the original grants reserving the right to change the rates of fare on the original lines of the two companies to which they applied, or constituted new contracts with such companies and their successors, which the city could not impair during the life of their franchises; and that an ordinance passed by the city requiring the consolidated companies to reduce the rates of fare on such original lines, aside from being impracticable in operation, since each of such lines had become a part of a larger system, operated together as a whole, was unconstitutional and void as an impairment of the contracts made by such subsequent ordinances.

5.—Same—Modification of Grant by City—Validity Under Ohio Statute.

Rev. St. Ohio, sec. 2502, providing that, after a grant or renewal of a grant is made by a municipal corporation, it shall not, during the term of such grant or renewal, release the grantee from any obligation or liability imposed by the terms of such grant or renewal, does not prohibit a city making a grant of a franchise to a street railroad company, in which it reserves the right to change the rates of fare to be charged, from thereafter modifying such contract on sufficient consideration. (Cleveland City Ry. Co. vs. City of Cleveland. Cleveland Electric Ry. Co. vs. Same, 94 Fed. Rep., 385.)

LIABILITY FOR NEGLIGENCE

ALABAMA.—Passengers — Personal Injuries — Complaint — Street Cars—Operation Without Conductor—Plea—Rules of Carrier—Negligence of Passenger—Death—Proximate Cause.

1. A complaint averring that plaintiff's intestate was a passenger on one of defendant's street cars, and that defendant then and there so negligently conducted said business that by reason of such negligence plaintiff's intestate received personal injuries, which caused his death, sufficiently alleges the negligence of defendant.

2. A complaint in an action for personal injuries to passenger, causing death, alleging that "deceased gave the usual signal to stop the car, whereupon the motorman * * * slowed up and stopped, or so nearly so as to render it reasonably safe for deceased to proceed to alight, whereupon deceased proceeded to alight, placing himself in a standing position on the platform or running board alongside the car for that purpose, * * * whereupon the motorman, negligently failing to look and see whether deceased

was in a place of danger, * * * started the car with a sudden motion, * * * thereby throwing deceased violently from said car," is not objectionable, in that it does not show whether he was injured by reason of attempting to get off the car after it had stopped, or while it was moving, and that it does not show that the motorman was informed of his desire to get off the car.

3. It is not necessary to allege the name of the carrier's employee whose negligence caused the injury.

4. Where a complaint alleges several negligent acts or omissions of a carrier, and that, combined together, they produced the result complained of, it is error to strike out the words charging one of the acts or omissions.

5. Whether the operation by a street railroad company of its cars without a conductor constitutes negligence is a question for the jury.

6. In an action for personal injuries to passenger, a plea that the car was equipped with bell and cord attached so that passengers could notify the motorman when they wished the car stopped should be stricken out, in the absence of an averment that the passenger did not pull the cord or ring the bell.

7. A rule of a street car company that passengers must not leave its cars while they are in motion is a reasonable one.

8. A passenger cannot be charged with negligence in violating a rule of the carrier, unless he knew the rule.

9. Whether a passenger was guilty of negligence in going upon the running board of the car preparatory to alighting, while it was in motion, was a question for the jury.

10. Negligence resulting in an injury to decedent's finger, which produced blood poisoning, causing his death, is the proximate cause of such death. (Armstrong vs. Montgomery St. Ry. Co., 26 So. Rep., 349.)

ARKANSAS.—Carriers—Personal Injuries — Evidence — Conclusions of Fact—Admissibility—Relevancy—Res Gestæ—Declarations After Injury—Trial—Prejudicial Instruction—Street Railroads—Trespassers—Degree of Care.

1. In an action to recover for injuries sustained while attempting to board a moving street car, the question, "what difficulty would you have had in getting on if it had remained going as it was when you started on it?" is inadmissible, as calling for the decision of a question which is within the exclusive province of the jury to determine.

2. Testimony of a witness in an action against a street railway company for damages for personal injuries, to the effect that he did not think it was dangerous to get on certain cars by the front platform, when they were running slowly, is inadmissible as determining a question within the exclusive province of the jury.

3. In an action by plaintiff, a boy 10 years of age, against a street car company for damages for personal injuries, evidence that boys had ridden on defendant's cars at different times without permission and at other times by invitation, and without paying fare, is incompetent, as not tending to prove that plaintiff was entitled to ride on the car he attempted to board at the time he was injured.

4. A statement by the motorman of the defendant company that it was due to his (the motorman's) own carelessness that plaintiff got hurt, made after the injury was complete, and plaintiff had been removed from where he had fallen, and was sitting in the car, and made with the obvious purpose of showing that the motorman was guilty of no intentional wrong, is no part of the res gestæ, and is inadmissible.

5. Testimony by a witness to the effect that he could not repeat the exact words used by plaintiff after the injury had occurred, but the impression left on his mind was that it was plaintiff's own fault, is properly excluded.

6. Where one of the defenses to an action against a street railway company was that the injury was due to plaintiff's own negligence, and not to any negligence on the part of defendant, and evidence was adduced to support this defense, and instructions were given upon it, an instruction that the only valid defense in the action was based on the theory that defendant's motorman had not invited plaintiff to ride, and for the jury to exclude from their consideration and decision the question whether, admitting the invitation to have been given, the plaintiff was guilty of such contributory negligence as would defeat his recovery, is highly prejudicial to the defendant.

7. Employees of a street railway company are under no obligation to keep a lookout to prevent boys, endeavoring to ride without permission and paying fare, from entering its cars while in motion, and owe them no duty save not to injure them wantonly.

8. A boy ten years of age, riding upon a street car without paying fare, by invitation of a motorman in charge of the same, who has authority to receive and let off passengers, is not a trespasser.

9. An invitation of a motorman to a boy to ride on the car is an act within the scope of his employment, for which he is responsible to his master, and if the boy accepts it innocently he is no trespasser, and it is the duty of the company to extend to him the diligence due to passengers of his age and discretion.

10. In entering, riding upon, and leaving street cars a boy ten years of age or over is bound to exercise prudence equal to his care, knowledge, and experience, and to that extent is held responsible in law for acts or omissions contributing to his own injury. (Little Rock Traction & Elec. Co. vs. Nelson, 52 S. W. Rep., 7.)

ILLINOIS.—Peremptory Instructions—Waiver—Injuries to Passengers—Instructions—Questions for Jury.

1. A motion made at the close of plaintiff's evidence to find for defendant is waived where it is not renewed at the close of the evidence, except as it is included in a series of instructions asked by defendant.

2. An instruction that a railroad company should exercise the highest degree of care, consistent with the practical operation of the road, to provide for the safety of passengers, is applicable in an action by a passenger of a grip car for injuries sustained by the sudden flying back of a brake lever, where there was evidence that the brake was in bad order.

3. In an action by a passenger on a grip car for injuries caused by a sudden flying back of a brake lever, his failure to obey the gripman's request to stand back was not negligence per se, where the car was crowded, and he was not informed of the danger. (West Chicago St. Ry. Co. vs. Johnson, 54 N. E. Rep., 334.)

ILLINOIS.—Action for Negligence—Personal Injury—Instructions.

1. In an action for personal injuries, an instruction authorizing a verdict for plaintiff on condition that she was injured because of defendant's negligence, "without negligence or fault on her part," is equivalent to requiring proof that she was in the exercise of ordinary care.

2. An instruction that the jury may disregard the entire testimony of a witness, when it is palpable that he has intentionally testified falsely as to some material matter, and is not corroborated by other evidence, could not mislead them to suppose that they should not disregard the testimony of a witness intentionally falsifying if there were others of the same kind who testified in the same way.

3. The jury were told that they were to consider all the testimony; that it was plaintiff's duty to establish her case by a preponderance of the evidence, and a verdict for defendant was directed if the evidence was equally balanced, if it preponderated for defendant, or if they were in doubt as to the preponderance; that the burden of proof was not on defendant, and, if the preponderance did not show an act alleged essential to recovery, their verdict should be for defendant. They were also told to consider all the evidence, and if it preponderated for defendant, or if they were unable to decide, they should find for defendant. *Held*, that the jury could not have understood an instruction that a "preponderance of the evidence" does not necessarily mean the greater number of witnesses, but that such evidence as produces conviction in the minds of the jury will constitute such preponderance, to mean that they might disregard the evidence for defendant.

4. From an instruction to a jury, in relation to estimating damages for pain and suffering due to a personal injury, and the future consequences reasonably certain to result, that they might "themselves make such estimate from the facts and circumstances in proof, by considering them in connection with their knowledge, observation, and experience in the business affairs of life," it could not be inferred that they might consider injuries outside the evidence, of which they might individually know. (North Chicago St. Ry. Co. vs. Fitzgibbons, 54 N. E. Rep., 483.)

LOUISIANA.—Injury to Person on Track.

The plaintiff in a suit for damages against a railroad company for injuries caused by defendant's car running over him, shown to have been alongside or in a position close to the track, with his legs across the nearest rail, and in that condition receiving his injuries, must, in order to recover, show with reasonable certainty that, notwithstanding his gross imprudence in thus exposing himself to peril, the defendant's motorman could, by the exercise of ordinary care, have averted the accident. 2 Thomp. Neg. p. 1105, sec. 1; Id. pp. 1157, 1158; Pierce, R. R. p. 330; Patt. Ry. Acc. Law, pp. 51, 55, 61; Railway Co. vs. Ives, 12 Sup. Ct. 679, 144 U. S. 429, and line of authorities there cited; McGuire vs. Railroad Co., 16 South. 457, 46 La. Ann. 1543. (Kramer vs. New Orleans City & L. R. Co., 26 So. Rep., 411.)

MARYLAND.—Master and Servant—Liability of Master for Torts of Servant—Willful and Wanton Acts—Instructions.

1. A master may be held liable for an act of his servant, though willfully or wantonly committed, when it was within the scope of his employment, and done in the performance of the master's business.

2. Whether an act of a servant was within the scope of his employment, and done in the course of his service, and for the master's benefit, is usually a question of fact for the jury.

3. The mere fact that a plaintiff suing for a personal injury resulting from the alleged negligent act of defendant's servant testifies that, in his opinion, the servant acted willfully and maliciously, or even feloniously, does not entitle the defendant to an instruction directing a verdict in his favor.

4. Where no reference is made to the pleadings in the prayers for instructions, the correctness of such prayers must be determined solely by the evidence. (Baltimore Consol. Ry. Co. vs. Pierce, 43 Atl. Rep., 940.)

MARYLAND.—Crossing Track—Failure to Stop and Look—Instructions—Contributory Negligence—Duty of Motorman.

1. The failure of a pedestrian to stop and look before crossing the tracks of a street railway will not, under all circumstances, constitute such contributory negligence as will prevent recovery.

2. Negligence on the part of plaintiff will not defeat his right to recover, unless it is such that but for it the misfortune could not have happened; nor if the defendant, by the exercise of care on his part, could have avoided the consequences of such negligence.

3. The court may modify a request of defendant to charge that plaintiff cannot recover if she contributed to the injury, by adding, "unless the motorman saw, or could reasonably have seen, the peril of the plaintiff, and failed to exercise ordinary care to avoid the accident."

4. The question of negligence, in cases of personal injuries from street railroads, is primarily one for the jury; and it is only when the facts are undisputed, or where but one reasonable inference can be drawn from them, that the question becomes one for the court.

5. Where a track occupies nearly the entire bed of the street, leaving only six feet between it and the curb, so that one, in crossing the street, would reach the tracks in a few steps after he came into the view of the motorman, and plaintiff is injured, while crossing, by a car approaching at the rate of ten or eleven miles an hour,—so fast that the motorman was unable to stop the car after discovering her,—she may recover, although negligent, if the jury find that the motorman should have slackened his speed and had his car well under control in approaching the crossing, and kept a sharp lookout for persons about to cross the track. (Baltimore Consol. Ry. Co. vs. Rifcowitz et al., 43 Atl., 762.)

MASSACHUSETTS.—Defective Roads—Evidence—Notice of Injury.

1. In an action against a street railway company for personal injuries caused by defendant's failure to construct its road to the road commissioner's satisfaction, as required by Pub. St. c. 113, sec. 32, the testimony of an assistant commissioner who had charge of the locality where the accident happened, that he saw the work and was satisfied, is admissible to show that the work was done to the commissioner's satisfaction.

2. Pub. St. c. 52, sec. 19, requiring notice of an injury in a highway to be given within thirty days to persons by law obliged to keep the highway in repair, is applicable where an injury is occasioned by a street railroad company's failure to keep its road in repair as required by chapter 113, sec. 32. (Maloney vs. Natick & C. St. Ry. Co., 54 N. E. Rep., 350.)

NEW JERSEY.—Frightening Teams.

Where an electric car, running upon and along a public highway at the ordinary and usual rate of speed, and without lessening the same, runs into and through a pool of water on the tracks of the railway, thereby throwing the water up, out, and in front of the car, and up, out, and upon the front and sides thereof, and causing, by so running through such water, an unusual, loud, roaring, and hissing noise, by reason of the water being gathered and hurled around and through the trucks and wheels of the car, and throwing therefrom, and so causing a horse driven by the plaintiff along the highway to become frightened and uncontrollable and to run away, throwing the plaintiff from his carriage and injuring him, a case is presented which requires its submission to the jury, upon the question whether the railway company, by its servants operating such car, has exercised reasonable care to protect the plaintiff from injury in his use of the highway. The case of McCann vs. Traction Co., 36 Atl. 888, 59 N. J. Law, 481, followed, and the principles established applied. (Ayars vs. Camden & S. Ry. Co., 43 Atl. Rep., 678.)

Indorsement of Standard System of Accounting

At the eleventh annual convention of State Railroad Commissioners, held in Denver, Aug. 10, the committee on classification of construction and operating expenses of electric railways made the following report:

To the Eleventh Annual Convention of Railroad Commissioners:

At the ninth annual convention of Railroad Commissioners, held in St. Louis in May, 1897, the following resolution was passed:

Resolved, That a special committee of three be appointed by this convention to prepare a form of classification of the construction expenses and operating expenses of electric roads, to correspond as far as practicable with the forms approved by this convention, and adopted by the Inter-State Commerce Commission for steam roads, and that said committee be authorized to invite the co-operation and assistance of the Association of American Railway Accounting Officers; also of the National Street Railway Association, or any other persons possessing expert knowledge appertaining to the subject, and to report the result of their proceedings to the next annual convention of this body.

The persons appointed to carry out the purposes of this resolution were: William O. Seymour, of Connecticut; Ashley W. Cole, of New York, and R. S. Kayler, of Ohio. The committee apponted by the Association of American Railway Accounting Officers to co-operate with the foregoing committee were:

H. M. Kochersperger, Comptroller of the New York, New Haven & Hartford Railroad Company; M. Riebenack, Assistant Comptroller of the Pennsylvania Railroad Company; H. D. Bulkley, Comptroller of the Baltimore & Ohio Railroad Company. The committee as thus constituted, met in New York City in April, 1898, and mapped out its work, closely modeled after the forms of the classification of the construction and operating expenses of steam roads, but the items chargeable under each head of the various accounts were not completed, and we found it impossible to perfect it in time to present to the tenth annual convention, held in Washington in May, 1898. We therefore reported progress, and asked for an extension of time for the completion of the work, which the convention readily granted. At the time of this meeting in New York City it was learned that an organization was in existence known as "The Street Railway Accountants' Association of America," which had been engaged for two years preparing such a classification as we had been instructed to prepare. In accordance with the terms of the resolution appointing us, we sought and obtained the co-operation and assistance of this organization, to which we are indebted for the form herewith presented for your consideration and adoption. It was found that the form prepared by the street railway accountants was so much more advanced in its preparation, so complete and full in its details, and so well adapted for its purpose, owing to the familiarity of those who prepared it with street railway accounting, that we deemed it wise to abandon the work which we had commenced and advise the indorsement and adoption of the form prepared by them. Several slight modifications in the form have been made at the suggestion of the railway accounting officers, and as it is now presented it is unanimously approved and recommended to this convention by your committee and the railway accounting officers associated with us. Emanating from their own accounting officers, the form is more likely to be universally adopted and used by the street railway companies than if prepared and submitted by those entirely outside of their organization, especially if they are assured by our action that it will be accepted and approved by the various State Commissions to which they are required to make annual reports. Your committee desire to publicly express their sincere thanks to the committee of the Street Railway Accountants' Association of America, who are the authors of this classification, and whose names, positions and addresses are prefixed to this report, for the cordial and generous manner in which they have contributed the results of their laborious and extended deliberations for our consideration and adoption; also for the valuable assistance rendered by J. D. Green, auditor of disbursements of the Pennsylvania Railroad, who represented Mr. Riebenack upon the committee; to Col. N. H. Heft, superintendent of electric construction on the New York, New Haven & Hartford Railroad Company, who kindly gave us the benefit of his expert knowledge of electrical matters; to Col. Charles R. DeFreest, recently clerk of the railroad commissioners of New York, whose assistance and advice were much appreciated; to Henry F. Billings, clerk of the railroad commission of Connecticut, who kindly consented to officiate as stenographer of the committee; and, finally, to the committee of the Association of American Railway Accounting Officers, who were associated with us, without whose advice and assistance no good thing can be accomplished in devising correct methods of railway accounting.

Respectfully submitted for the committee,

Wm. O. Seymour, Chairman.

This indorsement was the result of the meeting held by the committee in New York on July 11, and reported in the last issue on page 536. To the report was appended the standard system of accounting of the Street Railway Accountants' Association of America, with the slight changes mentioned in the August issue.

Seventeenth Annual Convention of the New York State Street Railway Association

The New York State Street Railway Association will hold its seventeenth annual meeting at Ithaca, N. Y., on Tuesday and Wednesday, Sept. 12 and 13. A most attractive programme has been arranged for the meeting, and a large attendance of both street railway managers and representatives of manufacturing companies is assured. Ithaca is well fitted for a convention city. It possesses good hotel accommodations and an excellent meeting place, while Cornell University offers an interesting field of study to those interested in electrical development and scientific matters in general. The faculty of that institution have expressed much interest in the coming convention, and the programme of the entertainment includes an inspection of the college buildings and the several departments, with a short description of each department by the professor in charge.

The entertainment of the delegates will also include a trolley ride to the picturesque environs of Ithaca, including a trip on Cayuga Lake, with luncheon served on the boat, a special entertainment and band concert at Renwick Park, and the customary banquet on the evening of the first day.

Ithaca possesses unusual scenic attractions, some of the natural beauties in the immediate vicinity rivaling anything found elsewhere in the East. Ithaca Gorge in itself draws hundreds of visitors each year, its many water falls and glens presenting a panorama seldom equaled. A few of the falls easily reached from the city are Triphammer Falls, the upper fall of the gorge; Ithaca Falls, 140 ft. high and nearly 200 ft. wide; Enfield or Lucifer Falls, 150 ft. high, and Taughhannock Falls, 215 ft. high, this being the highest fall in the State. From this flow of water are obtained the water powers of Cornell University and the Ithica Street Railway Company.

Cayuga Lake is a beautiful body of water and is as changeable in its moods as the ocean, at times being smooth as glass, again rippled with tiny waves, and at times, during high winds and heavy storms, its shores are lashed with white caps and breakers. At its head the street railway company has laid out and developed Renwick Park, now one of the most popular resorts of its kind in the State.

These natural attractions, together with the University buildings and grounds, are well worth in themselves a trip to Ithaca, and viewed as they will be under the thoughtful guidance of the reception committee, the delegates to the Ithaca meeting will long remember with pleasure, this occasion.

But the entertainment features of the convention will not be permitted to interfere with the business side. The officers of the association are very anxious that the meeting shall be of the greatest possible practical value, and to this end have sent the following list of every-day subjects to every street railway company in the State with the request that a representative make a selection therefrom and prepare a paper thereon. Should any subject of interest not embodied in the list suggest itself, any company is invited to adopt the same and send a paper upon that topic. The list suggested is as follows:

Rail Welding.
Track Bonding.
The Third Rail.
Storage Battery.
The Repair Shop.
Induction Motors.
Care of Dynamos.
Car Mileage Record.
Indemnity Insurance.
Municipal Ownership.
"The Metallic Circuit."
The Three-Phase System.
Street Railroads vs. State.
Loss of Current in Returns.
General Track Construction.
Inspection of Car Equipment.
Transfers, Their Use and Abuse.
"Receipts from Other Sources."
Street Railways vs. Automobiles.
Points on Overhead Construction.
Long Distance Power Transmission.
Impracticability of Reduction of Fare.
Suggestions on Financial Organization.
Maintenance and Repair of Car Bodies.
Pleasure Resorts as Traffic Stimulators.
Signal Systems for Single Track Roads.
Air and Power Brakes for Electric Cars.
Care and Inspection of Wheels and Axles.
Local Railway Employees' Benefit Associations.
Fuel Economy of Railroad Engines. (Allotted.)
The Power Station, from an Economic Standpoint.
How Can We Increase the Efficiency of Employees?
The Proper Instruction of Motormen and Conductors.
Compressed and Liquid Air for Street Car Operation.
Fenders and Other Means for Prevention of Accidents.
Experiments on Resistance of Rail Bonds. (Allotted.)
Freight and Express Service on Interurban Electric Lines.
The Mutual Relations of Municipalities and Street Railroads.
Statistics of Street Railway Construction and Operation. (Allotted.)
Polyphase Equipment Used in Cornell University; Illustrated by Polyphase Apparatus. (Allotted.)

The presentation and discussion of brief and concise papers (limited to twelve minutes) upon practical subjects like these, will be a highly instructive and prominent feature of the meeting.

In addition, four members of Cornell faculty have consented to contribute papers to be read, as follows:

"Statistics of Street Railway Construction and Operation." Harris J. Ryan, professor of electrical engineering.

"Experiments on Resistance of Rail Bonds." Professor H. H. Norris, electrical engineering department.

"Fuel Economy of Railroad Engines." R. C. Carpenter, professor of experimental engineering.

"Polyphase Equipment Used in Cornell University." (Illustrated by practical exhibit of polyphase apparatus.) Professor H. J. Hotchkiss.

President Rogers has sent to all roads in the State a letter urging upon them the benefit, importance and necessity of having one or more of the practical men from each company in attendance at the convention. He also says:

"It is earnestly hoped that the smaller roads of the State will actively participate in the proceedings of the meeting, particularly in the preparation of papers and the ensuing discussion, also that non-member street railroads will send representatives authorized to join the association."

Mr. Rogers has also extended a very cordial invitation to representatives of all manufacturers and dealers in street railway supplies and apparatus, to participate in the benefits and pleasures of the convention, and urges such concerns to send one or more delegates. Ample space in close proximity to the place of meeting, for the exhibit of supplies, models, etc., will be furnished free of expense to those who desire to avail themselves of the privilege.

Preparations for the Chicago Convention

A meeting of the general committee having in charge the arrangements for the coming convention at Chicago, of the American Street Railway Association, was held on the 14th of August at the office of J. M. Roach, general manager of the Union Traction Company, at 444 North Clark Street, Chicago. The meeting was attended by the chairmen of all the various committees and was called to order by T. C. Penington, secretary of the association, when, on motion, J. M. Roach was elected permanent chairman. The first business transacted was the filling of the vacant chairmanships of the various committees. The two committees on hotels and entertainments were consolidated and J. M. Roach was elected chairman in place of the late M. K. Bowen. The plans for entertainment and excursions were outlined and approved by all present. The programme includes a reception and dance at the hotel, a visit by rail to the drainage canal, a tally-ho trip to the parks on the South Side, and to the museum in Jackson Park, a visit by trolley cars to the stock yards, and the regular banquet. For the entertainment of the ladies of the association during the forenoon of each day's session, several carriage drives about the city and a visit in a body to some of the leading department stores, as well as to the public library and art institute on the lake front, will be arranged.

The committee on information and direction was authorized to prepare a book giving a map of the street railway lines of the city, with directions as to how to reach any of the parks or other important places in and about the city, together with a directory of local committees. Sufficient money was pledged by the representatives of the street railway companies present to carry out the programme and to meet all incidental expenses. The committee on space reported that all the space in the Tattersall Building had been engaged by exhibitors and a plan was outlined for securing additional space from the city in the neighboring streets and alleys.

All the committees are at work on their various assignments, and it is the intention of all that the Chicago convention will in its

attendance and interest, as well as in the matter of entertainment, eclipse any conventions that have previously been held.

The Tattersall's Building is 355 ft. x 146 ft. and the interior arrangement is shown in the illustration herewith. The partitions that now cut off the main floor from the floor under the gallery, however, will be taken down, so the entire floor will be open and no exhibit will be hid away from view.

In sending goods to the convention for exhibition purposes, manufacturers should remember the following directions:

All goods should be marked with the consignor's name, and directed to Tattersall's, Chicago, care of H. W. Smith, successor to Anderson Transfer Company, 1618 State Street. Bill of lading or advice that goods have been shipped in his care should be sent to Mr. Smith, giving particulars in regard to shipment. Goods will be delivered to the proper assigned space in the exhibition hall. All goods should be shipped early to insure delivery in time and all charges prepaid. All articles intended for the exhibition must be delivered at the building by the agent or owner, and at his expense, but the local committee has made arrangements with H. W. Smith (successor to Anderson Transfer Company) to haul and deliver all shipments to and from the building at low rates if directed in his care. All electrical connections for power and extra lights must be made at the expense of the exhibitor. The committee on exhibits will make contracts with carpenters, electrical workers and laborers at regular prices, so the exhibitors will not be overcharged for lumber, labor, etc.

Friday, the 20th, has been set apart by the executive committee for the examination of exhibits. No session of the association will be held on that day and no entertainments of any kind will be given by the local committee, so all delegates will have ample time to examine the displays made by the supply-men.

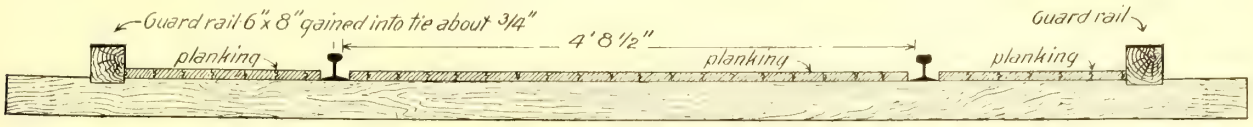
INTERIOR OF CONVENTION HALL, CHICAGO

Four Cent Fare Proposition in Milwaukee

On July 31 the City Council of Milwaukee appointed a special committee to confer with the officers of the Milwaukee Electric Railway & Light Company with a view of obtaining, if possible, a reduction in the rates of fare charged, and of bringing about a better understanding and more harmonious relations between the city and the company. To this committee the company has signified its desire to do all in its power to secure these desired results, and offers the following concessions on both sides as a basis of agreement.

The concessions which the company is willing to make are:

1. A gradual and increasing reduction in the rates of fare, until a 4-cent rate is secured by the sale of commutation tickets.
2. The permanent establishment of the transfer system.
3. The extension of the railway lines to the city limits at points necessary for the convenience of the people in the several localities interested.
4. The company is willing, in case the city desires, and has the power to purchase the railways and physical property of the company within the city, to grant an option to purchase on terms to be agreed upon, or, determined by arbitration.



For these concessions the company holds the city should grant the following:

1. Franchises upon certain streets which will enable the service to the public to be improved, and the railway system perfected.
2. An extension of the railway franchises for ten years.

The London County Council will install about 10 miles of underground conduit electric railway.

Trolley Accident Near Stratford, Conn.

What will probably prove to be the most disastrous accident which has ever happened on an electric road occurred near Stratford, Conn., on Aug. 6, when a car on the Shelton Street Railway, filled with passengers, jumped the track near the south end of a long bridge that crosses a deep ravine about 1½ miles from Stratford. The accident occurred about 3 o'clock in the afternoon, and the car fell about 50 ft. to the valley below. It turned completely over in its descent, and the weight of the motors and truck drove the floor against the top of the car, crushing many passengers. About twenty-eight passengers perished, while several others were severely injured. The Shelton Street Railway is a new line, recently opened between Shelton and Stratford. It is about 9 miles in length, runs along the western shore of the Housatonic River, and connects at Stratford with the systems of the Bridgeport Traction Company and the Milford Street Railway Company. The car to which the accident occurred was No. 2, of the Milford Street Railway.

SECTION OF TRACK CONSTRUCTION ON BRIDGE

From Stratford the tracks follow the highway in a northerly direction, until just before the ravine is reached at which the accident occurred. They then leave the highway and descend a grade of about 3 per cent a distance of some 700 ft. until the southern end of the bridge is reached. The latter crosses what in winter is an ice pond, but which, in summer, during dry weather, is a sort of morass. The track is laid with 4 in. T-rails, with flat head and sides; and 12 ins. outside of each T-rail is the usual wooden guard rail, 6 ins. x 8 ins. This guard is bolted to the ties, but is gained somewhat to fit into the ties, so that its effective height is reduced about an inch. The space between the rails and between the guard rails and the rails is planked for the greater part of the length of the bridge, including the part at which the car ran off the track. The company had ordered steel guard rails, to be laid inside the service rails, but they had not arrived.

The car was a 9-bench open car, mounted on a single truck, with a wheel base of about 7 ft. The depth of wheel flange was about three-quarters of an inch.

The testimony given before the Coroner's Jury seems to indicate that the motorman descended the grade leading to the bridge at a high rate of speed, and that the car commenced to oscillate and sway badly just before it reached the bridge, the cause being either the springing of the track on the embankment, owing to its having been recently built, or to the sudden change from a descending grade to the horizontal track, on the bridge, or both. The wheels jumped the track after the car had run about 40 ft. on the bridge. The car then ran about 30 ft. on the planking, climbed over the guard-rail, and left the bridge about 60 ft. beyond the point where it had left the rails. The evidence showed that when the car left the rails the current was turned off and the brakes set.

The decision of the Coroner's Jury was to find the motorman criminally negligent in running the car at a dangerous rate of speed; also that the company was negligent in allowing an imperfect condition of its track on the day of the accident, and in not enforcing the rule as to speed in approaching the bridge. The following recommendations were also made:

"First, that all cars be required to stop before crossing the bridge at Peck's Mill, 30 ft. distant from the bridge, at either end.

"Second, that all trolley bridges have inside guard rails and that the outside guard rail be not less than 8 ins. high and be lined with iron.

"Third, that no man be allowed to act as motorman for a trolley car until he shall have qualified before some competent board of examiners and be licensed therefor.

"Fourth, that the number of working hours of motormen and conductors be reduced, and that they be allowed a reasonable time for their meals.

"Fifth, that the Governor convene the Legislature at the earliest possible date, for the purpose of creating a commission with ample power, whose duty shall be to supervise the construction and operation of trolley lines."

VIEWS OF WRECKED CAR TAKEN ON THE DAY FOLLOWING THE ACCIDENT

Combination of Special Work Manufacturers

The names of the constitutent companies of the American Switch Company recently incorporated with $11,000,000 capital were announced last week. They are as follows: Weir Frog Company, Morden Frog & Crossing Works, Johnson R. R. Frog & Crossing Company, Eliot Frog & Switch Company, New York Frog & Crossing Company, Ramapo Iron Works, Cleveland Frog & Crossing Company, Carlisle Manufacturing Company, Paige Iron Works and Pettibone, Mulliken & Co.

The capital is divided equally into 6 per cent preferred stock and common stock. The company, it is said, will have a working capital of $1,600,000 in cash, and in addition has pig iron and manufactured goods on hand worth $700,000. Two new plants are to be constructed at once out of the capital on hand, after which, it is stated, there will still be a liberal working capital in the treasury.

Three Cent Fare Ordinance in Detroit

The Common Council of Detroit passed, and on Aug. 16, the Mayor signed, an ordinance providing that all street railway companies in that city shall charge no higher rate of fare than eight tickets for a quarter. The city holds that whereby under the old ordinances the companies are authorized to charge "not to exceed 5 cents," the city retains the privilege of regulating the amount charged to a "reasonable rate."

On the same day the new resolution was passed the Detroit Citizens' Street Railway Company obtained from the United States

District Court an order restraining the city from enforcing or attempting to enforce the new ordinance. The restraining order is returnable Sept. 4, when a permanent injunction will be asked for.

Consolidation of Albany and Troy Systems

Anthony N. Brady is authority for the statement that a consolidation of the street railway systems of Albany and Troy, N. Y., will be perfected within a few days. It is further stated that the consolidation of the Albany and Troy systems will be followed by the absorption of the Troy & New England Railroad Company, and also street railways in Saratoga, Rensselaer, Washington and Warren Counties, and in Vermont, which will give the consolidated company a monopoly of street car traffic from Albany to Lake George, on one side of the Hudson, and from Albany and Troy to Sand Lake, New York, and Bennington, Vt., on the other. It means, too, that the new company will be a powerful rival for the local business, so long enjoyed by the New York Central and Delaware & Hudson Canal Company's systems, which has made what is known as the Albany and Troy Belt Line one of the best, if not the best paying piece of steam railroad properties in the country.

The Albany Railway Company controls and operates all the street railroads in the Capital City, and its road to Troy has been particularly profitable. The Troy City Railway owns all the street railways in Troy, with lines to Green Island, Cohoes, Waterford, Lansingburg and Albia. The Troy & New England Railroad is a continuation of the Albia branch and runs to Sand Lake and Averill Park, two summer resorts largely patronized by residents of Albany and Rensselaer Counties. Ex-United States Senator Murphy and Anthony N. Brady are largely interested in the Troy and Albany roads, and they and their friends control the Troy & New England.

The Troy City Railway is capitalized at $4,000,000, of which $2,000,000 is in 5 per cent gold-bearing bonds. The Albany Railway has $2,000,000 in 5 per cent bonds, and $1,750,000 in common stock. The Troy & New England Company is capitalized at $500,000.

End of Street Railway Contests in Atlanta in Sight

The bitter fight over franchises in Atlanta, Ga., and its development into proposed municipal ownership, seems about to reach a settlement.

The electric railway committee of the City Council, after giving a hearing, which lasted several weeks, to the rival claimants—the Collins Park & Belt Railroad Company, and the Atlanta Railway & Power Company, has recommended an ordinance which will be far-reaching in its effects. This ordinance, which was passed by the City Council on August 21, after a long and heated session, proposes to regulate and govern the street railways, in a manner that has never before been attempted in Atlanta. It also looks to the leasing of all the lines of the Atlanta Railway & Power system after the expiration of its franchises in 1921, at a rental of 5 per cent of the gross receipts, and also the payment of the same tax by any other system then in existence. By their acceptance of the franchises just granted the two companies they become amenable to the new law.

The principal features of the law are as follows:

Section 4. The City of Atlanta reserves the right to regulate the location of tracks, wires, poles and conduits, and their construction.

Section 5. Any part of the lines of all street railway companies, not exceeding five blocks at any one point, may be used by any other street railway company, upon payment of just compensation.

Section 6. After the expiration of the original grants to the Atlanta Consolidated Street Railway Company all companies shall pay (beginning May 20, 1921) a percentage of their gross receipts, not exceeding 5 per cent per annum.

Section 8. The rate of fare for one continuous trip from 5 A. M. to 12 P. M. shall not be more than 5 cents, and from 12 P. M. to 5 A. M. not more than 10 cents.

The section 6 is the direct outcome of the voluntary offer of the Atlanta Railway & Power Company to pay a part of their net receipts to the city. This offer was declined, as its acceptance entailed a refusal from the city to grant franchises to competing lines.

During the hearing the accusation was made that the application for franchises by the Collins Park & Belt Railroad Company was for speculative purposes, and made in order to sell their electric light plant to the Atlanta Railway & Power Company. The Collins Park road is required, on its acceptance of franchises granted them, to give the city a bond for $40,000 that work will begin in four months, and the system completed in twelve months. Their offer of $50,000 toward the construction of a new bridge was accepted.

One of the most interesting features of the new law is an amendment made to section 6, with the object of preventing the two systems from consolidating. Its substance is as follows:

"Should the two systems now competing consolidate, unite or by any means direct or indirect, have the same or reciprocal management, or any understanding as to the operation of the two systems in unison, the 5 per cent tax on gross receipts shall at once become effective on both roads." It is provided, however, that a reciprocal use of transfers between the two lines may be permitted without subjecting the companies to the tax, until 1921.

Consolidation of Machine and Tool Manufacturing Interests

A new company, formed by the consolidation of the Niles Tool Works of Hamilton, Ohio; the Pond Machine Tool Company, of Plainfield, N. J.; Bement, Miles & Company, of Philadelphia, and the Philadelphia Engineering Works, was incorporated at Trenton on Aug. 14. The company is known as the "Niles-Bement-Pond Company," and has a capital stock of $8,000,000, $5,000,000 of which is common and $3,000,000 6 per cent cumulative preferred. The four companies included practically control the heavy machine tool trade, including the manufacture of gun carriages, in this country, employing together over 3000 men. The temporary offices of the company are with the Corporation Trust Company in Jersey City, and the New York offices will probably be at 136 Liberty Street.

The directors of the new concern are: Alexander Gordon, president of the Niles Tool Works Company; Charles A. Moore, of Manning, Maxwell & Moore; Clarence S. Bement and Frederick B. Miles, of Bement, Miles & Company; Gordon Shillito, Thomas T. Gaff and Daniel H. Holmes, of Cincinnati; Frederick W. Gordon, of Philadelphia; George T. Reiss and James P. Cullen, of the Niles Tool Works Company; E. C. Burke, of Cleveland, Ohio; Walter L. Clark, of the Niles Tool Works Company; A. C. Stebbins, of the Pond Machine Tool Company; W. S. McKinney, of Pittsburgh, and Robert C. McKinney. Officers—President, R. C. McKinney; first vice-president, James P. Cullen; second vice-president, A. C. Stebbins; third vice-president, Walter L. Clarke; treasurer, Charles L. Cornell, of the Niles Company; secretary, E. N. C. Davis.

Trolley Contact Spring Case

On Aug. 1, the General Electric Company secured in the United States Circuit Court, District of New Jersey, a decision against the Rahway Electric Light & Power Company, of Rahway, N. J., in its suit for alleged infringement of the Anderson patent, No. 412,155. This patent covers an invention for the arrangement of certain metallic conducting brushes intervening between the end of a trolley wheel and the frame or fork in which the wheel is journaled, for the purpose of maintaining a good electric connection against them in the ordinary system of overhead underrunning trolley.

The defense made by the defendant was, lack of invention, a complete anticipation, lack of patentable novelty in view of the prior art, and entire lack of infringement on the defendant's part. The court, after very fully reviewing the case, decided that the Anderson patent, now owned by the General Electric Company, and dated Oct. 1, 1889, antedates other patents granted for spring contact devices on underrunning trolleys, and therefore gave judgment for the complainants.

Consolidation of Electrical Directories

It is announced that the E. L. Powers Company, of New York, has secured control of the "Electric Railroad List of the World," formerly published by the "Railroad Gazette," and has consolidated this list with the "American Street Railway Directory." By means of this combination the new publication will have the combined circulation of both directories, its scope enlarged, and the data improved in point of accuracy and completeness.

NEWS OF THE MONTH

A recent compilation shows that the tramway companies of Great Britain are using on roads now in operation, and have ordered for roads constructing, from 2500 to 3000 American electric motors, and nearly or quite 40,000 h.p. of American electric railway generators.

The American Mica Company, which has a capital stock of $3,500,000, and which will control the output of mica in the United States, has been incorporated under the laws of New Jersey.

C. B. Wisner, secretary of the Sills Mica Company, of Chicago, when asked regarding the new corporation, stated that besides his own company the Eugene Munsell Company, of New York, and the American Mica Company, of Boston, are interested.

The Twenty-eighth and Twenty-ninth Street Cross Town line of the Metropolitan Street Railway Company is now being operated entirely by compressed air cars from the power station at the foot of West Twenty-fourth Street.

A cablegram from Glasgow announces that the Glasgow Tramway Committee on Aug. 15 accepted the tender of the Edward P. Allis Company, of Milwaukee, for the engines for its new power plant. It is said the order amounts to £114,544.

At a meeting on Aug. 16, the directors of the Brooklyn Rapid Transit Company passed resolutions complimenting President Rossiter upon his able management of the road and the masterly way in which he handled and suppressed the recent strike.

A newspaper special dispatch from Chicago reads as follows: "John M. Roach, who has been president of the Chicago Consolidated Traction Company and also general manager of the Chicago Union Traction Company, has resigned his position as president of the Consolidated Company and Charles T. Yerkes takes his place. It is said Mr. Yerkes intends to give his active attention to the Chicago Consolidated Traction Company. He has also taken into the board with him John R. Walsh, president of the Chicago National Bank, and Harvey T. Weeks, a retired capitalist and active politician, who during the days of the elder Carter Harrison was the right-hand man of the Mayor." It is stated in addition that Warren F. Furbeck, vice-president of the Consolidated Company, has also resigned and has been succeeded by L. S. Owsley.

Albert L. Johnson has given out the following interview:

"We hope to get a franchise soon to build and operate a conduit electric road from the heart of London to Brighton. Our surveys and specifications are about completed, and by the latter part of September everything will be in shape to lay before the controlling powers of London. We shall offer the people of the British metropolis very great inducements to give us the franchise we seek. There is nothing like the American sub-trolley service there, and we propose to build and equip a road in first-class style and carry passengers from London to Brighton for sixpence, which is twelve and one-half cents of our money. The present rate of fare between those two points is equivalent to $1.50 of American money."

The distance from the city limit of London to Brighton is 45 miles. From the city limits to the heart of London is about 7 miles more, so that the American syndicate offers to carry passengers 52 miles for sixpence.

The Board of Railroad Commissioners has made arrangements for a test of brakes for street surface railroad cars. Twenty-two permits have been issued for that purpose, and each person or company receiving a permit is allowed to equip with brakes one of the cars of the Metropolitan Street Railway Company, and the tests will be made, three or four on one day at Lenox Avenue and 146st Street, New York City. The first series of tests were made on Tuesday, Aug. 29, and Wednesday, Aug. 30, between the hours of 9 A. M. and 5 P. M. On these days from five to seven brakes were tested. Notice of the dates of tests to follow will be given in the daily newspapers and in the street railway publications. An invitation to be present is extended to those who are interested in the operation of street surface railroads.

An illustration of the way in which the investing public is rapidly absorbing street railway and electric lighting securities may be obtained from the fact that the United Electric Securities Company, of Boston, has, under date of Aug. 1, called for redemption at 103 and accrued interest over $600,000 of its collateral trust 5 per cent bonds outstanding. These bonds have been secured by underlaying 6 per cent first mortgage bonds of electric railway and lighting companies, which have now been sold at a substantial advance over the prices at which they were rated as collateral, and the proceeds of these sales are to be used to retire the bonds as above stated.

It is semi-officially announced that Charles P. Clark, president of the New York, New Haven & Hartford Railroad, may, on account of poor health, find it necessary to retire from that office, and his resignation is expected at the October meeting. This announcement will be received with no less regret in electric railway circles than in the steam railroad world, for it is largely due to Mr. Clark's interest and faith in the application of electricity to heavy passenger transportation problems that the experiments with the third rail and overhead systems, which have resulted in so many valuable developments, have been carried out on the N. Y., N. H. & H. R. R. It is stated, however, that Mr. Clark will still retain his position as a director of the road.

It is further announced that John M. Hall, the present vice-president of the system, will be elected to the presidency on the retirement of Mr. Clark.

The Birmingham Railway & Electric Company has voluntarily increased the wages of its conductors from 15 to 17½ cents an hour, and motormen from 12 to 15 cents an hour. The increase applies only to those who have been in the employ of the company one year or over.

The Birmingham Traction Company has voluntarily increased the wages of its employees. New motormen will receive 13 cents an hour for the first six months' service, 14 cents for the second and 15 cents thereafter. In the same manner the conductors will get 14, 15 and 16 cents per hour, according to the length of service. Heretofore motormen have been receiving 13 cents and conductors 14 cents. The company has also posted a notice that a ten-day vacation on full pay will be given in October to the motormen and conductor who shall have made the best record before that time. A second prize will also be offered.

The Little Rock Traction & Electric Company has increased the wages of motormen and conductors, who have been in the company's employ two years or more, 3 cents an hour.

The Denver Tramway Company, on Aug. 12, gave the women of the Old Ladies' Home of that city a free ride about the city. The ladies were taken to the City Park, where the company had provided luncheon for its guests.

The Derby Street Railway Company has notified its motormen and conductors who have been in the company's employ not less than five years that they will receive $2.50 a month increase; when they have been in the service ten years there will be another increase of $2.50, and then an increase of the same amount for each succeeding five years.

Corporation Counsel Robertson, of Hartford, on Aug. 8, rendered an opinion that street railways may sub-lease their lines for a freight business provided they own the cars used and that they are run by their motormen. He states that all street railways have a right to carry freight, but as to sub-letting their property, unless their charter gives them permission, they cannot do it except under the conditions named.

The trolley express between Manchester and Hartford was boycotted so persistently by the merchants of the former place that it has been discontinued.

One of the buildings of the electric light plant of the Washington Traction & Electric Company was recently destroyed by fire. The loss is estimated at $50,000. The building was used for the storage of electrical appliances, and for stable and office purposes.

The Indianapolis Street Railway Company will erect a large car plant and repair shops on West Washington street. The new buildings will be 200 ft. x 200 ft., and will be fully equipped with the necessary machinery and facilities for building street cars complete, with the execption of motors and trucks. Life guards and other supplies will be manufactured. It is understood these shops will be able to fill orders from outside companies as soon as the needs of the Indianapolis Street Railway Company have been supplied. In addition to the new plant the company has let contracts for a new car barn 100 ft. x 180 ft., on Louisiana Street. This will have storage capacity for fifty cars.

The Mayor of New Albany has appealed to the Supreme Court to compel the operation of the New Albany Railway, which was recently discontinued.

Flint & Hanlon, contractors, have commenced the work of lowering the elevated street railway of Sioux City, now the property of the Sioux City Traction Company. About 1500 ft. of this structure will be taken down at this time. The remainder will be lowered some time next year, and the material will be used in the construction of steel bridges.

The Cedar Rapids & Marion City Railway Company has put in effect a new scale of wages. All conductors who have been on a regular run for one year have been given an increase of 20 cents a day; motormen who have been on a regular run for two years receive an increase of $1 a month, and motormen having regular runs for five years past receive an increase of $2.50 per month.

The Detroit Electric Railway Company has refused the demand of the executive board of the railway employees for an increase of 4 cents per hour in wages. There has been a call for a meeting of the employees, and a strike is threatened.

Judge Lillibridge, of the Circuit Court, July 27, delivered a decision permanently enjoining the street railway companies of Detroit from carrying freight over their lines within the city. Hitherto the cars have carried freight over the city lines, although there has been no specific authority for so doing.

The report of the various street railway companies operating in St. Louis, for the second quarter ending June 30, as to the number of trips made and passengers carried is as follows:

	Trips.	Passengers.
Lindell Railway	284,856	6,470,246
St. Louis & Suburban	41,669	3,244,924
Union Depot	201,024	7,071,668
Citizens' Railway	78,970	2,375,986
Cass Avenue	153,534	2,611,273
Jefferson Avenue	36,916	382,496
Missouri	181,204	4,164,153
Southern Electric	50,346	1,688,771
St. Louis Railroad	247,140	3,274,000
Peoples' (April 1 to 11, inclusive)	6,349	97,350
St. Louis Traction Co., Peoples' Div., April 12 to June 30	44,329	766,877
Total	1,326,337	32,227,686

The officials of the Wellston, Creve Coeur Lake & St. Charles Railroad Company, of St. Louis, celebrated the completion of the line to the company's grove at St. Charles Rock and Lucas Lane, by giving an entertainment at the grove, Aug. 12.

The Metropolitan Street Railway Company, of Kansas City, is planning to build large shops for the purpose of manufacturing many of its own supplies including iron poles, fenders, etc.

The electric light companies of Hoboken, Elizabeth and the People's Light and Power Company, controlling the electric light plants in Newark, the Oranges, Montclair, Jersey City, Bergen Point and neighboring towns and villages, have beeen consolidated. The new company will be known as the United Electric Company of New Jersey. The consolidation of the electric light properties is looked upon as a step in the ultimate consolidation of the electric railway interests with the gas and eletric light companies in that section of the State. Bernard Shanley, John D. Crimmins and the Widener-Elkins syndicate are interested in the consolidation.

The Plainfield Street Railway Company and the Brunswick Traction Company have entered into an agreement for issuing transfers to each other's lines at Dunellen.

The South Orange Avenue car barn of the North Jersey Street Railway Company, of Newark, was destroyed by fire recently. Two parlor cars were destroyed, together with five snow sweepers, seven new cars for its Orange and Passaic line and sixty-two other cars. The loss is estimated at $140,000. The fire is supposed to have been caused by lightning entering the building on the trolley wires. The power house escaped serious damage.

The Canandaigua Lake Transportation Company and the Canandaigua Electric Light & Railroad Company have arranged a special feature known as "Bargain Days." On Monday and Thursday afternoons of each week the companies have arranged to carry passengers on both boat and railway at a greatly reduced price. The privilege of stopovers is also allowed.

The Augusta Railway & Electric Company will construct a park at Summerville. The proposed park will be a spacious affair of fifteen acres, situated on the Wrightsville Road in the vicinity of the old Camp Mackenzie. It will be laid off in grass plots interspersed with fountains and beds of various flowers, and the walks to be lined with shade trees. A large two-story pavilion will also be provided. The lower, or ground story of this pavilion, will be used as a car house, where will be kept an extra supply of cars, so that large crowds can easily be handled. The upper portion will be fitted up as a first-class dance pavilion of the latest design. The construction of the park is expected to begin at an early date.

The Lewiston, Brunswick & Bath Street Railway Company, of Lewiston, and the Maine Central Railroad are engaged in a rate war. The Maine Central has reduced its rates so as to conform with those of the electric railway, and an interesting war will probably be the result. The electric railway rates will probably be again cut.

The New Orleans Traction Company recently donated the receipts of one night at West End to the Charity Sewing Room of New Orleans.

President Vreeland, of the Metropolitan Street Railway Company, of New York, has granted a three days' vacation with full pay to all the conductors and motormen of the system who remained loyal during the attempted strike on July 19-20. This privilege is equivalent to a gift of from $20,000 to $25,000 from the company to the men.

The Brooklyn Rapid Transit Company has fixed the rate of pay of motormen in its employ as follows: Motormen on surface cars, $2 per day; bridge train motormen, $2.25 per day, and regular elevated motormen $2.50. The elevated motormen are composed chiefly of locomotive engineers, who accepted positions as motormen when the Fifth Avenue branch was equipped with electricity. These men suffer a decrease of $1 per day in wages.

Owing to the failure of the employees and the officials of the Chippewa Valley Electric Railroad Company, of Eau Claire, to come to an agreement on a scale of wages, the men went out on strike, and on Aug. 6 the company was forced to discontinue the operation of its cars. Many obstructions were placed on the tracks and mobs threatened the street railway property in various parts of the city.

The Milwaukee Electric Railway & Light Company has voluntarily increased the wages of employees in the company's service five years from 19 to 20 cents an hour.

The question of municipal ownership of street railways and conduits bids fair to become one of the vital issues before the Council of Richmond. It is stated the following resolution will soon be introduced: "Be it resolved by the Council of the City of Richmond, That the committee on charter changes is hereby instructed to report to this body amendments to the charter of the city of Richmond, as follows: 1. Granting power to the city to construct, or acquire by purchase, maintain and operate street railways for the carriage of passengers and freight for hire and reward, and in furtherance of such powers to issue bonds and secure the same upon such franchise, trackage, rolling stock, &c. 2. Granting power to the city to construct, maintain rent or lease underground conduits within the city of Richmond for the conduct of telephone, telegraph and other electrical conductors, and in furtherance of such powers to issue bonds and secure the same upon such conduits."

The Memphis Street Railway Company has increased the wages of motormen and conductors who have been in the company's employ one year or over from 14 to 15 cents an hour.

One of the cars of the Nashville Street Railway, while passing over the Cumberland River bridge, was thrown into the river, a distance of twenty-five feet, by a span in the bridge giving away. Fortunately very few people were injured and the car and equipment suffered little damage, considering the severity of the accident.

A daring robbery took place shortly after midnight, July 31, at the car barn of the Newport & Fall River Street Railway Company, in Portsmouth. Five masked men entered the barn, subdued and robbed the employees who were there, and then entered the office, emptying the money locker and making two unsuccessful attempts to blow open the safe. One of the employees, who was bound, after several hours succeeded in freeing himself and tried to telephone for assistance, but found that the wires had been cut. It was found necessary to dispatch cars to Newport and Fall River before the authorities could be notified. It is said that the robbers secured about $500.

The Allentown & Lehigh Valley Traction Company has decided to comply with the request of its motormen and conductors for an increase in wages. The most cordial relations exist between the men and the management, and the decision to increase the wage scale was largely influenced by the respectful manner in which the request was made. The old rate was 15 cents an hour for both mortormen and conductors. The new scale gives 15 cents an hour for the first year, 16 for for the second and 17 thereafter. This places the employees of this company among the best paid street railway men in Pennsylvania.

New Company for the Manufacture of Heavy Electrical Apparatus

A meeting of the stockholders of the Scott-Janney Electric Company, recently incorporated at Trenton, with a capital of $30,000,000, was held in Philadelphia, Aug. 21. This company is organized for the purpose of manufacturing, on a large scale, electrical apparatus and supplies, including alternating and direct current apparatus, motors, dynamos, etc., up to 2000 volts capacity, arc lamps and transformers, under patents granted to Gordon J. Scott, and will come into direct competition with the General Electric Company and the Westinghouse Company. The company has in operation a large manufacturing plant at Twenty-second Street and Washington Avenue, Philadelphia.

The Scott direct current railway system differs materially from the ordinary systems, and for it the following claims are made:

First.—It can be applied to any of the existing railway motors.

Second.—When so applied will enable the existing motors to do more efficient work.

Third.—It will enable present motors to start and accelerate a car or train of cars to maximum running speed from 30 to 40 per cent faster than at present without taking any more current, or will start them as fast with from 20 to 30 per cent less current.

Fourth.—This system does away with all jerking of cars or trains even while starting very quickly.

Fifth.—This system when used in connection with Scott railway motors, which are of a new type and very light, efficient and powerful for the size, will return 20 to 30 per cent more work at the car wheels than any other motors.

Sixth.—It makes no difference whether one or one hundred cars are in one train, as all motors in such train can be controlled from any car by fractions of a revolution, or by fractions of a pound at periphery of car wheels.

Seventh.—Any trolley system, overhead, underground, surface contact or third rail, will need only 65 to 70 per cent of the copper necessary with existing railway systems, or those which will use any other system of driving and control.

A. Langstaff Johnston, consulting engineer, has examined the workings of the system in detail, and has reported most favorably upon its merits.

The Scott-Janney Company also proposes to introduce what it calls a gaso-electric system, which it is announced contains all the advantages of an independent and self-contained motive power, secured by compressed air or storage batteries without their attendant dead weight and complicated machinery, and at greatly reduced cost for installation and maintenance.

The following officers for the year were elected: Frank Le Bar, Philadelphia; Henry A. Sage, Ogdensburg, N. Y., president of the Ogdensburg Heat, Light & Power Company; Gordon J. Scott, Philadelphia; General Frank Reeder, Easton, Pa.; Robert Alexander, Philadelphia; William B. Hill, director of the People's Trust Company, New York; Edward A. Abbott, Concord, N. H.; J. F. Tapley, New York; James B. Dill, director of the Trust Company of America, New York, and the Federal Steel Company; W. H. Wolverton, treasurer of the Bell Telephone Company, New York; Charles W. Drake, former vice-president of the Missouri Pacific Railway Company and a director of the American Trust Company, New York; Allen D. Laney, of the banking firm of Lathrop R. Bacon & Company, New York; T. Quincy Brown, president Atlantic National Bank, Boston; Daniel O'Day, of the Standard Oil Company, New York; Charles Watson, chief engineer American Sugar Refineries Company, New York; C. W. Ogden, New York; Frank R. Hansen, New Jersey; George H. B. Martin, New Jersey; William S. Janney, R. F. Lopez and Charles F. Walter, Philadelphia.

Recent Electric Roads in England

It is reported that the projected Isle of Thanet electric road will soon be built. This new line, which will be 10 miles long, will pass through Ramsgate, Margate and Broadstairs, three of the most popular English seaside resorts. The contract will probably be worth £30,000. Orders have just been sent the Edward P. Allis Company, of Milwaukee, for two 300-h.p. engines. Additional orders will also be placed with this concern.

Among English trolley lines equipped with American electric appliances is the Staffordshire Tramways Company. The Potteries Electric Traction Company, which is an extension of that line, is now nearing completion. The electrical part of the contract is worth about $100,000. The American Tube Works and Morris Tasker, of Philadelphia, supplied 1450 tubular steel poles.

Three horizontal compound condensing engines of 350 h.p. each were furnished by the McIntosh, Seymour & Company, of Auburn, N. Y. The General Electric Company made the generators. The motor trucks came from the Peckham Motor Truck and Wheel Company, of Kingston, N. Y. The insulators were ordered from the Albert & J. M. Anderson Manufacturing Company, of Boston, and all the copper was supplied by the Washburn & Moen Manufacturing Company, of Worcester, Mass.

The August issue of "Cassier's Magazine" is a special number devoted exclusively to electric railways. It contains about eighteen long articles on live street railway questions, written by as many different engineers, each an expert on the particular subject treated in his paper. Among the topics discussed are: "The Latest Developments in Electric Conduit Railways," by F. S. Pearson; "Electric Tramways in Great Britain," by Robert W. Blackwell; "Building an Electric Railway," by Lemuel W. Serrell; "Overhead Construction," by J. G. White; "The Development of the Tram Car," by John A. Brill; "Rails and Rail Joints," by M. K. Bowen; "Light Electric Railways," by Dr. Louis Bell; "The Multiple Unit System for Electric Railways," by Frank J. Sprague; "The Selection of Rolling Stock," by C. F. Uebelacker; "Storage Batteries and Electric Railways," by Herbert Lloyd; "Electric Railways in America," by W. J. Clark, etc.

Pennsylvania Street Railway Association

At a meeting of the Executive Committee of the Pennsylvania Street Railway Association, held recently, it was decided to postpone the eighth annual meeting of the association from the first week in September to Wednesday and Thursday, Oct. 4 and 5.

The meeting will be held at the Stevens House, in the City of Lancaster. Papers and addresses of interest to members of the association will be read and delivered at the first day's session, while the second day will be occupied with a series of entertainments of interest and attraction to members and visitors in attendance at the meeting.

Foreign Exports From America

The official figures of the foreign trade movement for the fiscal year ending June 30, 1899, have just been completed by the Treasury Bureau of Statistics, and show a very satisfactory improvement, both in gross and in detail. The total exports for the year amounted to $338,667,794, as against $290,697,354 in 1899. The greater part of this large increase is shown in the classes of manufactured iron and steel, which increased from $70,406,885 in 1898 to $93,715,951 in 1899. The differences in certain of the important detailed classifications appear in the following table:

	1898.	1899.
Cars and carriages	$3,424,419	$4,106,284
Copper ingots	31,075,636	34,476,343
Electrical and scientific apparatus	2,770,803	3,309,180
Steel rails	4,613,376	5,298,125
Steel wire	2,593,306	3,891,180
Builders' hardware and tools	6,428,332	7,842,372
Electrical machinery	2,052,564	2,736,110
Metal working machinery	4,618,683	6,491,586
Pumps and pumping machinery	2,023,034	2,710,654
Locomotive engines	3,883,719	4,728,748

Iron pipes and fittings	3,092,016	5,874,228

Annual Report of Brooklyn Rapid Transit Company

President Rossiter, under date of Aug. 21, has transmitted to the stockholders of the Brooklyn Rapid Transit Company the annual report of the company for the year ending June 30, 1899. Mr. Rossiter fully reviews the growth of the system, and after giving the cost of consolidation of the different properties now included and the results expected to be obtained from these consolidations, he says in part:

"It can now be said of the Brooklyn Rapid Transit system that in mileage of track it is the largest street railway system in the world, comprising 504 miles, or more than twice the trackage of the Metropolitan Street Railway Company, of New York, nearly 400 miles more than the Manhattan Elevated Railway Company, of New York, 60 miles more than the Union Traction Company, of Philadelphia, and 173 miles more than the Boston Elevated Railway Company, including the old West End Company. In amount of passenger earnings it surpasses every street railroad system in the world with the exception of the Metropolitan Street Railway Company, of New York."

The combined reports of all the companies now included in the Brooklyn Rapid Transit Company (comprising the Brooklyn Heights, Brooklyn City, Brooklyn, Queens County & Suburban, Brooklyn Union Elevated, Nassau Electric, Kings County Elevated, Brooklyn & Brighton Beach, Sea View Railroad and Prospect Park & Coney Island), give for the

Year ending June 30,	1897.	1898.	1899.
Receipts from passengers	$9,343,261	$9,877,001	$11,035,216

The table given below gives the operating statement of the Brooklyn Heights Company during the year ending June 30, 1899. The figures do not include the figures of the acquired companies prior to the time of acquisition. The method of operation is to have all the companies leased to the Brooklyn Heights Railroad Company, which is the operating company, and the income of the Brooklyn Rapid Transit Company consists of the surplus profits of the Brooklyn Heights Company, and such moneys as it may receive from the stocks and bonds held by it. The figures given below include the reports of the Brooklyn Heights, the Brooklyn City, Brooklyn, Queens County & Suburban, and the Sea Beach Railway for the entire year, and the Brooklyn Union Elevated and the Nassau Electric for three months only of the fiscal year. For purposes of better comparison the figures of the leased companies for the corresponding period of the preceding year are combined with those of the Heights Company, although they were not at that time, of course, a part of the Brooklyn Rapid Transit system.

OPERATING STATEMENT, BROOKLYN HEIGHTS RAILROAD COMPANY

Year ending June 30,	1898.	1899.
Gross earnings	$6,616,361	$7,412,435
Operating expenses	4,232,206	4,669,371
Net earnings	2,384,155	2,743,064
Income from other sources	*185,459	13
Gross income	2,569,614	2,743,077
Fixed charges	2,482,349	2,289,909
Surplus	$87,265	$453,167
Per cent operating expenses to gross earnings	63.9	62.9

*Includes income from guarantee fund ($181,370), which in the succeeding year was paid directly to Brooklyn Rapid Transit Company, and did not pass through operating company's account.

INCOME ACCOUNT, BROOKLYN RAPID TRANSIT COMPANY

Year ending June 30, 1899.

Receipts.		
From interest on bonds and loans	$188,395	
From profit on bonds sold	182,001	
From miscellaneous	425	
From Brooklyn Heights R. R. Co.'s surplus	471,555	
		$842,375
Expenses.		
For interest	$338,261	
For taxes and miscellaneous expenses	41,565	
		379,826
Surplus for year		$462,549
Accumulated surplus prior to June 30, 1898		215,579
Total surplus June 30, 1899		$678,128
Deductions from Surplus.		
For new equipment and construction on railroad properties	$300,482	
For extinguishing old deficiencies of B., Q. C. & S. R. R. Co. accrued prior to its acquisition by B. R. T. Co.	321,174	
Direct to profit and loss	1,931	
		623,587
Surplus carried forward		$54,541

Plant for the Manufacture of Electric Brakes

The Hubbard Brake Company is the name of a new concern formed for the purpose of manufacturing and introducing throughout the United States an electric brake of new design, patented by M. G. Hubbard, whose mechanical ability is well known through his connection with the McGuire Manufacturing Company, of Chicago, as engineer. He was the inventor of several of the McGuire specialties, including a snow sweeper, truck, etc. The officers of the new company are: M. G. Hubbard, president and general manager; George E. Pratt, vice-president; Charles Gilpin, secretary and treasurer. Mr. Pratt has handled high-grade street railway supplies for many years, and is well known throughout the trade. Mr. Gilpin is secretary and treasurer of the Andover Iron Company, and is interested in other iron and railroad enterprises.

The company's works are located in Chester, Pa., near the freight station of the P. W. & B. Railroad, on Sixth Street. Machinery is being installed, and it is expected the works will be in operation by September 1. The company is well backed financially, and it begins operations with a number of orders on hand.

The electric brake to be manufactured has been thoroughly tested under practical conditions, and has shown excellent results. It is claimed for the device that stops can be made easily and quickly without jerking or jarring; it will prevent flat wheels; its first cost is not high, and the maintenance charges are very small; it can be operated by any motorman and from either end of the car, a small controller handle being provided for the purpose; there is no undue strain on car body or truck, as in some air brake systems, and no extra strain on the car axles, as in some disk or axle brakes.

The Hubbard Brake Company is equipping cars at Spring City, Pa., with this brake.

Street Railways in Foreign Cities

An interesting investigation upon the operating conditions of street railways in different foreign cities has recently been conducted by the Royal Trust Company, of Chicago. The information was secured by direct correspondence during the last three months with the United States Consuls, resident in the different cities, so that it can be relied upon as being up to date.

Of thirty-seven cities in various parts of the world about which information was obtained eight own and operate the transportation lines, four own the lines and lease them to companies which operate them, and in three others provision is made for municipal ownership at some future date. In eight cities passengers are permitted to stand in the aisles; in the others it is forbidden.

In a few cities, Cork, Prague and Marseilles, there is a uniform 2-cent fare, but in most cases the fare varies with distance traveled. Where information regarding franchises could be obtained an interesting variety of terms will be noticed. The data are grouped under the cities as follows:

Basle, Switzerland, electric transit. All lines built, owned and operated by the city. Fare, 2 cents for short and 4 cents for longer distances. Passengers allowed to stand in aisles and on platforms.

Belfast, Ireland, horse cars. Fare, 2 cents a mile. Standing in aisles or on platforms not allowed. Company has fourteen-year franchise and pays no bonus, but has to pave and repair middle of streets traversed by its lines.

Berlin, Germany, electric, steam and horse cars, also elevated (steam) belt line. Fare, 2½ cents for two miles and 1 cent for every additional mile. No passengers allowed in aisles, but a designated number are allowed on each platform. Companies have to pave and repair streets through which their lines run and pay a substantial bonus to the city.

Berne, Switzerland, steam and compressed air traction. Fare, 2 cents a mile. No one is allowed to stand in the aisles. Fixed numbers are allowed on platforms. City is negotiating for purchase of the company's lines.

Brussels, Belgium, electric—underground and overhead trolley—horse and steam traction. Fares from 2 to 12 cents, according to distance. No one is allowed to stand in the aisles. Cars generally divided into two compartments—first and second class.

Buenos Ayres, Argentine, electric, steam and horse traction. Underground electric line being constructed. Lines owned by British companies. Fares, 10 and 20 cents (paper). Two postmen and one policeman allowed on front platform (free); three passengers allowed on rear platform. Companies pay 6 per cent of gross receipts to city.

Calcutta, India, horse cars, but to be changed to electric cars soon. Fares, 2½ to 4½ cents. No passengers taken on after seats are occupied. Franchise runs twenty-five years; company pays a fixed amount per mile per annum and keeps middle of street in repair.

Cape Town, South Africa, electric trolley cars. Fare, 6 cents for three miles. Passengers stand on front and rear platforms, but not in aisles. Cars are "double-deckers," made by Brill, Philadelphia. Company has twenty-five years franchise; cannot learn that it cost anything.

China, there is not a street car in all China.

Christiania, Norway, one electric line (five miles) and one horse car line (four miles). Other lines under construction. City intends to buy the lines as soon as franchises expire. The city is now building a short line as a public enterprise. Fares, 2¾ cents. Fixed numbers allowed to stand on platforms, but none in aisles. Companies made no direct payment for their franchises, which expire in 1924, but pay taxes on their property like other corporations. Cars are "double-deckers."

Copenhagen, Denmark, horse and electric traction. Fare is 2¾ cents for any distance. When all seats are taken no more passengers are taken on, and conductors are heavily fined if they exceed the licensed number. Amalgamated Company pays the city a certain percentage of gross earnings.

Cork, Ireland, electric lines. Fare, 2 cents for any distance. Passengers not allowed in aisles or on platforms. Company's franchise is unlimited; it pays nothing directly, but paves the middle of the street and furnishes electric light to city at reduced rates.

Dublin, Ireland, electric traction. Fare, 1 cent a mile; minimum fare, 2 cents. Cars are "double-deckers." Passengers not allowed in aisles except in rainy weather. Company pays city $2500 a year per mile of its line for right of way and also has to pave between its tracks and one foot on either side. Franchise runs forty years, with provision that city may buy the line after twenty years, paying actual market value of machinery and plant. In case of disagreement on price, the board of trade is to be the referee.

Edinburgh, Scotland, horse and cable cars. In six months the entire system will be cable. City owns entire system, which is operated by a lessee company. Fare, 2 cents a mile, except certain popular routes, for which the fare is 2 cents, although longer than a mile. Workmen's tickets between the hours of 5 and 7 A. M. and 5 and 7 P. M. daily, and Saturdays from 1 to 3 P. M., at 2 cents for two miles and 1 cent for each additional mile. No passengers taken on after all seats are occupied.

Florence, Italy, electric and horse traction. City owns the lines and leases them to private companies. Fares, 2 cents from outskirts to center of city and 3 cents across city. Passengers allowed on platforms, but not in aisles. Lessee company has a fifty-year franchise and guarantees the city at least $12,000 a year revenue, besides contributing $400 a year to a provident institution for street car employees and $300 to a cabmen's society. Profits over 7 per cent are shared by the company and the city.

Frankfort-on-the-Main, entire system being changed to electric traction. Fares, 2½ to 5 cents, according to distance. The city recently bought the entire system, paying $550,000 down and $75,000 annually for seventeen years. There are twenty miles of lines. Fixed number allowed on platforms; no one in aisles. Considerably reduced rates given to pupils going to school or to private instructors, to swimming baths, to conservatories of music, art schools, etc. Family tickets at greatly reduced rates are issued, provided the husband's income is not over $25 a month or the wife's not over $15, and provided there is no son over twenty-one years of age.

Germany, there are still a number of cities, of 15,000 to 50,000 population, which have no street railways of any kind—Pforzheim, Trier, Ratisbon, Colmar, Jena, Kaiserslautern, Worms and others.

Ghent, Belgium, electric traction. Fares, 3 cents first-class; 2 cents second-class. Passengers allowed in aisles and on platforms. Franchise runs fifty years from Jan. 1, 1898. Company pays city 17 per cent of gross receipts annually, but not less than $3860 (which amount the company deposits each 1st day of January in advance). Franchise provides for purchase of lines by the city before twenty years or after twenty years. Franchise also fixes minimum wages of conductors and mortormen at 78 cents a day, and of workmen at 68 cents, and a maximum day's work in summer at fourteen and one-half hours and thirteen and one-half hours in winter, with an interruption of one and one-half hours for meals.

Glasgow, Scotland, has thirty-seven miles horse car service and three miles electric street railway. City owns and operates entire system. Fares, 1 cent for first half mile, 2 cents for two miles, and 1 cent for each additional mile up to six miles (longest route). No transfers given. Rule that no more passengers are to be taken on after seats inside and on top are taken, but rule is not kept. Entire system is to be made electric by 1901.

Havre, France, trolley cars (Thomson-Houston). Fares, 3 cents first-class, 2 cents second. Passengers on front platform pay second-class fare and those on rear platform pay first-class. Transfers, 1 cent extra. No one allowed in aisles. Franchise runs fifty years from 1893. Company pays city 2½ per cent on its gross receipts, but not less than $3500.

Kingston, Jamaica, electric traction. Fare, 4 cents within any section—city is divided into three sections. Fare through three sections is 12 cents. Three front seats in each car are reserved as first-class, and fare is 6 cents instead of 4 cents. Tickets sold at reduced rates. Franchise runs thirty years. Company pays government 4 per cent of gross earnings and maintains streets it occupies to eighteen inches on each side of tracks. Passengers allowed in aisles and on platforms. Market cars run before 9 A. M. and after 5 P. M. for country people carrying produce—fare, 3 cents.

Liverpool, England, electric and horse cars, also lines of omnibuses. City owns all the transit lines. Fares, 2 cents for each "stage" or zone and 4 cents for entire three stages, four miles. Passengers allowed to stand in aisles and on platforms.

Lyons, France, electric, steam and horse traction. On steam lines locomotive draws trains of three long cars. Fares, for first-class (cushioned seats), 4 cents; second-class, 2 cents. Fourteen persons allowed on front platform and same number on rear. Nobody allowed to stand in aisles. Only one door in car for both entrance and exit. General tramway company pays $16,000 fixed annual tax and also 10 per cent on all receipts in excess of $2,000,000. Franchise provides for purchase by city after forty years.

Maracaibo, Venezuela, horse cars. Three companies. Oldest one pays 3½ per cent a month profit on its capital. Fare, 5 cents. Rule against passengers standing, but not heeded. Companies paid nothing, directly or indirectly, for their franchises, which have five years yet to run.

Marseilles, France, overhead trolley system being installed on all lines. Uniform fare of 2 cents. Company paves between

tracks and fourteen inches each side; also pays city small annual fee of $19,300; and when gross receipts aggregate $1,400,000 a further fee will be paid, as follows: For the next $200,000, $7720; for the following $200,000, $9650; for the subsequent $200,000, $11,580; and $12,000 for every additional $200,000. Electric trains are limited to four cars, not exceeding 118 feet, and speed is limited to twelve and one-half miles an hour. Franchise expires in 1950, when the State becomes owner of the company's tracks and other property located on the public domain. During the last five years of the concession, should it appear that the operating company fails to maintain the property in good condition, the State reserves the right to seize all the company's revenues, for the purpose of keeping up the same. The State will have the right to take all rolling stock, tools and similar movable property at a valuation fixed by experts, but will be under no obligation to buy more than suits its purposes or wishes. Upon the termination of the concession, should the State deem it useless to continue the operation of certain lines, the concessionaires will be required to remove their tracks and restore the streets to their original condition. The State reserves the right to purchase its concession at any time. The price, in such event, will be fixed by the net annual revenue of the seven preceding years, including the fees paid to the city. From the total thus obtained will be deducted the net revenue of the two last profitable years, and the average of the five remaining years will stand as the amount of an annuity, to be paid to the concessionaires during each unexpired year of the revoked concession.

Mexico (City), Mexico, cars drawn by mules. Suburban cars are larger and are drawn to outskirts by mules and thence to their destination by small American dummy engines (steam). Company is preparing to substitute electric for animal traction, but will retain the steam lines. Managers of company are Americans. Fares for city are 5 and 6 cents according to distance. Suburban fares are 12 to 30 cents. Passengers are allowed in aisles and on rear platform, but not on front platform.

Munich, Germany, electric, steam and horse cars. All lines are owned by the city. Fares, 2½ to 6 cents on horse cars, according to distance. Passengers not allowed to stand in aisles, but limited number allowed on both platforms.

Naples, Italy, horse cars and electric trolley cars. Fare, 2 cents on two back seats and 3 cents on cushioned seats; 2 cents to stand on front platform, 3 cents on rear platform. Company has fifty-year franchise; pays percentage of net profits to the city. Electric cars made in Schenectady, N. Y.

Paris, France, thirty-three lines of omnibuses drawn by two horses (with twenty-six to thirty places), fourteen lines of omnibuses drawn by three horses (with forty places), three lines of steam tramways, twenty-three lines of horse tramways, four lines of compressed air and electricity. All of the lines are controlled by one company, which has an exclusive franchise dated 1860 and expiring 1910. In 1896 the omnibus lines carried 129,000,000 passengers out of a total of 240,000,000 for all lines. Cars and omnibuses are "double-deckers." Inside fare, 6 cents (entitles passenger to transfer ticket); fare on top and on platforms, 3 cents. Passengers not allowed in aisles.

Prague, Austria, electric and horse cars. Lines all owned by the city. Fare, 2 cents. Passengers allowed in aisles and on platforms.

Rheims, France, horse cars; but change to electric traction is in progress. Fares, 3 cents for first-class and 2 cents for second-class. One cent extra for a transfer. Number of passengers on a car fixed by law. Franchise expires in 1945, and provides that from the net profits each year the company is entitled first to receive 5 per cent upon its invested capital, while the city is entitled to 25 per cent of any surplus above the 5 per cent. The remaining surplus goes to the company, except that after the company has carried three millions of passengers the city is to receive $1.15 for every additional thousand passengers carried.

St. Petersburg, Russia, horse cars, single track. Principal line bought by city last September, and being operated by city at a profit. The city has suits pending to obtain permission of other lines, when electric traction will be installed. Cars are "double-deckers." Fares, 2½ and 3 cents. A dozen different lines but no transfers. Passengers allowed in aisles and platforms. Cars slow down but seldom stop for passengers to get on or off.

Stockholm, Sweden, horse and steam traction. Fare, 2¾ cents. Five persons allowed on front platform, six on rear and ten inside. Company's franchise runs forty years from 1876. Company is taxed 5 per cent on its income.

Stuttgart, Germany, electric traction. Power furnished by a separate electric lighting company. Fares, 2 1-3 to 6 cents, according to distance. Cars are limited to a fixed number of passengers, but exceptions are made in case of storm, after theater, last night car, etc. Company pays city 2½ per cent of gross receipts.

Sydney, Australia, electric, steam and cable traction. All lines owned and operated by the government of New South Wales. Fare, 2 cents a mile. Laws against overcrowding are disregarded.

Tegucigalpa, Honduras, no street car in the country and only one railroad, fifty miles long.

Toronto, Canada, electric traction. Fares, 5 cents; after midnight, 10 cents. Tickets, six for 25 cents, or twenty-five for $1. Also tickets good from 6 to 8:30 A. M. and 5 to 6:30 P. M., eight for twenty-five cents. Sunday tickets, seven for 25 cents. School children's tickets, ten for 25 cents. Children under nine years, (not in arms), half fare. Passengers allowed in aisles and on platforms. Company's franchise given for twenty years with a renewal of ten years. Company pays city $800 a year for every mile of single track; also pays 8 per cent of gross receipts up to $1,000,000 and 10 per cent above $1,000,000. Company is also taxed upon its plant, poles, etc., except track.

Victoria, British Columbia, electric trolley cars. Fare, 5 cents. Passengers allowed to stand in aisles and on platforms. Franchise given for fifty years, for which the company pays nothing, either in the way of taxes or bonus.

Winnipeg, Manitoba, electric trolley line. Fare, 5 cents. Passengers taken on regardless of seating capacity. Franchise granted 1893 for thirty-five years without bonus or conditions, except that after eleven years the company must pay the city 5 per cent of its gross earnings and pave its track (8 ft.) uniform with pavement laid by the city.

Westinghouse Electric Company Abroad

The plans for the erection of a large factory for the construction of electrical machinery in England by Mr. Westinghouse, as outlined in the Street Railway Journal last month, seems to have attracted the liveliest sort of interest among English manufacturing circles. London "Engineering" publishes a long editorial on the subject, in which it advises the English manufacturer to consider well the growing competition of American manufacturers, which competition has increased owing to the readiness with which the American manufacturer introduces improved methods and tools to facilitate his work. It regards the establishment of the proposed works in England by Mr. Westinghouse as a most important step in the history of manufacturing in England, and as beneficial to the English manufacturer in that he will be able to study American methods close at hand. The adoption of these methods is regarded as essential to the maintenance of English prestige.

In a recent interview with Mr. Carnegie on the subject, published in the London "Daily News," that prominent operator says that, if permitted by the British workman to introduce American methods, the success of Mr. Westinghouse in his Manchester establishment will be undoubted. He also adds, apropos of the increasing use of electric power, that at the Carnegie works in Pittsburgh all kinds of motive power are being discarded in favor of electricity.

Company for Making Veneer

The Seguine-Axford Veneer Company is the name of a new corporation organized to manufacture veneer for street car and railroad car ceilings, sides, backs, ends and seats, and in fact all the articles for which veneer can be used. The manufacture of veneer for car use will form a very large proportion of the company's business, and it will make a specialty of this class of work.

The general manager of the company is W. P. Seguine, who for many years was connected with the Frost Veneer Seating Company, and who is a well-known expert on the subject of the manufacture and use of veneer. Associated with Mr. Seguine are E. K. Seguine and William Baldwin Axford. The company's factory and office are located on Pacific Avenue, Jersey City, N. J., and its cutting mills are at Harriman, Tenn. The company will also make a specialty of the manufacture of wood tiling.

The Hipwood-Barrett Car & Vehicle Fender Company, of New York, has just recently opened in Chicago, a branch office in the Marquette Building, room 449. All the western business will be handled from this office, which is under the management of George E. Weiler. The office has already had credited to its efforts orders from the Montreal Park & Island Railway Company, of Montreal, and also from the Metropolitan Street Railroad Company, of Kansas City.

Large Power Station in Colorado

One of the latest power plants to be placed in operation in the West is now running at La Bella, Col., and will be used to operate the Florence & Cripple Creek and Golden Circle railroads, and to supply power, water and light to the mines, mills, samplers, etc., of the Cripple Creek District. The building proper covers a space of about 10,000 sq. ft. and is 50 ft. high.

In the boiler room are to be found six large boilers of the Babcock & Wilcox type, arranged in three batteries. These are of 3000 h.p. capacity under normal conditions, and should the service require, they can deliver, readily, steam for 4500 h.p. The boilers are arranged in a very novel manner, for instead of being constructed directly upon masonry foundations, as would ordinarily be done, they are mounted on elevated steel beams and a space is thus left underneath all of them. Instead of carrying the smoke and gases to the stack over the boilers, in the usual way, they are carried downward into this basement space left beneath, and thus taken to the stack. The space above the boilers is thus left perfectly clear and nothing is visible in the boiler room to indicate the presence of a flue. The heat and the obstruction of the large flue is thus done away with in the boiler room. The space above the boilers is entirely clear for the steam pipes and valves and these are readily accessible. A further use is made of the basement under the boilers in the handling of ashes. Instead of drawing the ashes from the fires into the room, they are dropped into the basement to an ash conveyor and are carried directly to the cars on the track on the outside of the building. The stokers are of the Babcock & Wilcox type, having an endless chain grate.

Extending the full length of the building and adjoining both the boiler room and the pump room is the engine room, this room is 110 ft. long and 45 ft. wide and contains a large compressor and three large engines, driving electrical generators. The combined engine capacity is 3000 h.p. Over the entire engine room spans a powerful traveling crane; by a novel design this crane is made to extend out of the building and overhang the railroad track and wagon road so that any piece of machinery is readily transferred to any portion of the engine room. One of the conspicuous features of the engine room is the large compressor, this is of the Ingersoll-Sargent make and is driven by an Allis Corliss engine. The compressing cylinders and the steam cylinders are both compound and the steam cylinders are condensing. The high pressure air cylinder has a diameter of 22 ins., while the low pressure cylinder has a diameter of 40 ins., both having a stroke of 48 ins. The capacity of the compressor being some 5000 ft. of free air per minute, fifty drills could be operated, and even at the high altitude of 10,000 ft. above sea level, thirty-five drills can be operated.

Adjoining the compressor are the large engines coupled to the huge generators of electricity. The electric power will be used to operate the Florence & Cripple Creek Railroad from Alta Vista to Cripple Creek and the Golden Circle Railroad from Victor to Cripple Creek via Vista Grande. The surplus power will be used to operate the hoists, pumps, compressors, crushers, etc., in mines, mills, samplers, etc., throughout the district. The engines are of the horizontal compound condensing type and were built by McIntosh, Seymour & Company, of Auburn, N. Y. The normal capacity of each engine is 750 h.p.; they are, however, capable of supplying 1100 h.p. each when occasion demands. The main shaft of the engines carries the electric generators, this shaft being 16 ins. in diameter. The generators were built by the General Electric Company, of Schenectady, N. Y. These machines are of the latest type and generate a three-phase alternating current of 6600 volts at 3600 alternations per minute. This is reduced to 440 volts by transformers.

Test of Kinetic Motors

A test of a new double truck motor car, recently built by the Kinetic Power Company, was made Aug. 17, on a 7½-mile branch of the Long Island Railroad, near Babylon, N. Y. The trial was witnessed by a number of foreign consuls, who had expressed an interest in the system, together with the representatives of several of the technical papers. The road upon which it was conducted is part of the "Garden City extension" of the Long Island Railroad, formerly operated by steam locomotives, but now operated by the Kinetic motor car mentioned, which makes several trips daily.

The car was recently built by the Jackson & Sharp Company, and one truck is equipped with two 8 in. x 12 in. cylinders, while the other truck is an idle one. The reservoir, or boiler, is carried under the car body between the trucks, and is stored with hot water at a pressure of about 160 lbs., from a stationary boiler before starting. A small fire is carried to make up for the heat lost by radiation, and the steam is exhausted into a condenser, located on the roof. The steam pressure is reduced to about 30 lbs. before being admitted to the cylinders. On trial the car ran the length of the route, 7½ miles, in fifteen minutes, though faster time than this has been made.

After the trial the visitors were afforded an opportunity of riding over the local street railway system in Babylon, which is also operated by Kinetic motor cars.

Stillwater-Mechanicville Street Railroad Company

The Westinghouse Electric & Manufacturing Company has completed the electrical equipment of the Stillwater-Mechanicville Street Railroad Company. The power house is at the northern end of the line at Stillwater, whence the tracks are run southward, following the Hudson River 9 miles through Mechanicville to Waterford, forming a junction with the Troy City and Albany lines. The railroad passes through an extremely picturesque country, attracting much traffic from the lovers of nature, and is a favorite route for excursion and pleasure parties from Albany and Troy. The track is mainly level, the maximum grade being 7 per cent for 400 yds. The roadbed is first-class, 90-lb. girder rails being used in the town sections, and 75-lb. T rails on the country roads.

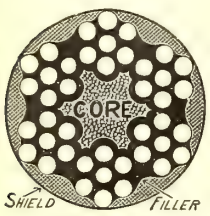
Power is obtained from the Hudson River. A wooden dam at Stillwater gives a 7-ft. head, the water being piped to the power house to operate two 250-h.p. Leffel turbines, which run at 500 r.p.m. The turbines are both geared to the same shaft, revolving the shaft at about 160 r.p.m. Under this shaft is direct connected a 250-kw. Westinghouse direct current "engine type" generator, 550 volts. At the other end of the shaft is a friction clutch, which, when occasion requires, direct connects the generator to a 250-h.p. steam engine. The steam power is for use when the flow of water in the Hudson is insufficient to operate the turbines. A booster is installed to raise the voltage at the southern end of the line. All the cars have Westinghouse electric motors, the smaller cars have two 25-h.p. motors. There have recently been added four open and three closed cars to carry eighty passengers; these larger cars are equipped with two 35-h.p. Westinghouse motors.

Electric Railway Contracts in England

A contract has been signed with the British Thomson-Houston Company, Ltd., covering the electrical equipment, engines, cars, trucks, etc., for that portion of the London United Tramways upon which it has been resolved to introduce electric traction, in Hammersmith, Chiswick, etc. The contract includes six 250-kw. 550-volt direct-current traction generators and one 500-kw. 94-r.p.m. 5000-volt three-phase generator, driven by vertical Corliss engines; thirteen 75-kw. 5000 volts primary, 330 volts secondary, static oil-cooled transformers; four 200-kw. 500-r.p.m. 550-volt rotary converters; one motor generator set, consisting of a 500-kw. three-phase synchronous motor, direct coupled to two 250-kw. direct-current generators on combination bed plate; two 75-kw. 400-r.p.m. 525-volt direct-current generators for lighting purposes; also complete switchboards for the whole plant, and 100 cars of top-seat pattern, each mounted on two trucks and equipped with two G. E.-58 motors. Series-parallel controllers and magnetic brakes are also included in the contract.

It is intended to have the new service in operation next June.

The Bristol Tramway Company has also recently signed a contract with the British Thomson-Houston Company, Ltd., for four 500-kw. tramway generators coupled direct to vertical cross compound engines of the Corliss type, together with three 30-kw. motor generators, and two 50-kw. lighting machines; also a complete switchboard for this machinery, 150 single-truck double-deck cars complete, each of which will be equipped with two G. E.-52 motor, series-parallel controllers and magnetic brakes.



Other recent orders include thirty G. E.-52 double motor equipments, with electric brakes, for the Sheffield corporation; eight cars with Peckham trucks, G. E.-52 double motor equipment and electric brakes, for the Ashton-Under-Line; eleven cars, with Peckham trucks, G. E.-52 double motor equipments and K-10 emergency stop controllers, and the complete equipment of the Isle of Thanet Electric Railway. This will include about 1000 kw. in generator capacity.

The business of the Vulcanite Fibre Company, of Wilmington, Del., has grown to such an extent that the management has been compelled to add to its already large works. The new building will be a three-story brick addition to the old factory, and will be 135 ft. x 30 ft. Frank Taylor, of this concern, reports that they were never so busy in the history of the company as at present.

Protection of Wire Ropes

Wire rope for operative purposes is used in so many widely different ways, and is subjected to so many varying conditions, that the preparation of an exterior protective coating for ropes of this nature has presented a serious problem. A dry atmosphere, tending to speedy oxidation, brittleness and consequent peeling off of the coating, presents itself in one location; while in another, a moist atmosphere, or possibly a continuous subjection to water, sometimes impregnated with acid, prevails. In addition, most exposed wire ropes are subject to the extremes of winter and summer.

The illustration herewith presented shows the application of a special coating termed "Wire Rope Shield," which, it is claimed, possesses the requisites of a satisfactory coating, in being tenacious, pliable, lubricating and water and acid proof. The high points of the strands are protected from abrasion by a lubricating film deposit, and a like deposit prevents the chafing of the wires. The satisfactory use of this shield on wire ropes leading from an office building to an extremely wet mine, strongly impregnated with acid, and to dredging machinery constantly subjected to water, indicates its efficiency. The "filler" shown in the illustration is a flexible, cushioned lubricant, protecting the strands from abrasive wear, and reinforcing the work of the shield, in effectually sealing the rope against water soaking, acid or gaseous attacks. The Ironsides Company, of Columbus, Ohio, manufactures this shield and filler.

SECTION OF ROPE

Drawings of Electrical Apparatus

The "Electrical World and Engineer," of New York, announces that at the request of the German publisher, it will accept American subscriptions at the German price (20 marks, or $5, for each portfolio) for Prof. E. Arnold's two portfolios of working drawings of electrical apparatus.

The portfolios are sold separate. One contains sixty-four sheets 16 ins. x 21 ins. in size, of dimensioned drawings of direct-current dynamos and motors; and the other forty-eight sheets of the same size, giving dimensioned drawings of single and polyphase alternating current machines and transformers. The drawings show the machines of the leading manufacturers of Europe, more than twenty firms being represented.

Subscriptions will be received until Sept. 15. The portfolios will be delivered within a month later.

The Victoria Hotel

In the Victoria Hotel delegates to the convention will find a pleasant home during their stay in Chicago. It is adjacent to convention headquarters and centrally located on Michigan Avenue facing the Lake Front Park, where a fine view and a cool lake breeze add to the attractions of its rooms. The cuisine and service throughout are unexcelled.

The Victoria is conducted on both the American and European plans and makes special rates for delegates.

Elastic Self Locking Steel Nut

Numerous ingenious arrangements for securing a self-locking nut for bolts have been suggested, but few of these have been successful in procuring the desired results under all conditions of strain and vibration. The National Elastic Nut Company, of Milwaukee, Wis., however, is now placing on the market what it calls an "elastic" nut, and which it claims will positively lock itself on the bolt wherever placed, and never work loose.

SELF-LOCKING NUT

This result is obtained, it is stated, by the peculiar construction of the nut, which, instead of being punched from a solid bar, as is usually done, is made by bending a flat thin bar around into a ring, and then pressing this ring into the form of a nut, which is done by special machinery. The nut is tapped, or threaded slightly smaller than the bolt, so that when put on with a wrench it is distended a little, and the joint formed by the coming together of the two ends of the ring opens slightly (about 1-64-in.), developing a constant grip on the bolt which prevents it from unscrewing.

Recent Work of the Falk Company

The Falk Company, of Milwaukee, Wis., reports that its construction department has been extremely busy this season. Some of the work done has been the completing of the Oshkosh & Neenah Railway, owned by the Citizens Traction Company, of Oshkosh. The line embraces 17 miles of track and overhead work. The Falk Company had the contract for the complete construction, including grading, power house, etc., and the furnishing of all material and machinery. George Kobush, of the St. Louis Car Company, is president of this company. The Falk Company also laid the greater part of the existing track in Oshkosh. In Kansas City, Mo., this company has completed laying the 2 miles of track in Grand Avenue, where a 9-in. rail is laid in concrete beam and with asphalt pavement. It has also nearly completed the construction of the Northeast Electric line in Kansas City, which is 8 miles long and is partly laid with concrete beam and partly with tie construction, and asphalt paving.

The company has also recently secured a contract for track construction of the Third Street line in Kansas City, Kan., 2¾ miles in length. All of the track mentioned in the two cities is cast-welded. In addition contracts have been secured and work will be commenced soon on the welding of 7 miles of track for the new East Side Electric Railway in Kansas City, Mo.

The special work department of the Falk Company was crippled by its recent fire. However, the new buildings upon which work was begun immediately, are nearly completed and will be turning out work within sixty days. These new buildings are all modernly equipped throughout. All machinery will be operated by electric motors. In addition to the Third Avenue welding now nearly completed in New York, the company has the contract for welding 5000 joints for the Union Railway Company, of New York, also the contract for welding the lines of the North Hudson Railway Company in Hoboken, N. J., 2000 joints for the Canton & Massilon Street Railway in Ohio, and is beginning the work of welding 6000 joints in Washington, D. C., for the Anacostia & Potomac River Railway.

The company's gear and pinion department has been running night and day for weeks, and in addition to its large American business, has also secured a number of good contracts abroad, among these being a second order from the Société de Anonyme des Tramways de Cairo.

Reorganization of a Prominent Boiler Company

The National Water Tube Boiler Company, of New Brunswick, N. J., is now in a better condition than ever before to supply the increasing demand for its type of boilers. A reorganization of the company has recently been effected, new capital introduced and the new owners will spare no efforts to sustain and even increase the enviable reputation enjoyed by the former company for careful and painstaking workmanship and excellency of materials employed in all departments of the plant. Mr. Schenck, the former manager, will continue to act in that capacity. He is thoroughly acquainted with the workings of the business, as a result of his wide experience, and will no doubt do much to improve the condition of the concern.

The new directors of the company are: Hugh McKeag, Philip Weigel, Jr.; Robert J. Smith, P. M. Welsh, P. G. Polhemus, C. A. Schenck and Hugh Boyd. The officers are: President, Hugh McKeag; vice-president, P. G. Polhemus; secretary and manager, C. A. Schenck; treasurer, Philip Weigel, Jr.

Personal

MR. ROBERT O. HARRIS has resigned the position of counsel for the Massachusetts Electric Companies.

MR. E. H. JENKINS has been elected president of the San Antonio (Texas) Street Railway Company, vice W. H. Weiss, resigned.

MR. P. A. B. WIDENER has resigned from the presidency of the board of managers of the Philadelphia National Export Exposition.

MR. A. C. GARDINER, treasurer of the Dartmouth & Westport Street Railway Company and secretary and treasurer of the

Union Street Railway Company, of New Bedford, has resigned both positions, to take effect Sept. 1.

MR. ARTHUR WARREN, manager of the advertising department of the Westinghouse Electric & Manufacturing Company, returned from Europe on Aug. 5.

MR. GEORGE F. SIEBEL will have charge of all the street railway companies centering in Taunton, Mass., that are owned by the Massachusetts Electric Companies.

MR. E. S. DIMMOCK has been appointed general manager of the Bay Cities Consolidated Railway Company, of Bay City, Mich., in place of Mr. S. L. Nelson, resigned.

MR. JAMES H. WILSON, president and general manager of the Mobile Light & Railway Company, Mobile, Ala., has been taking a short vacation at Asbury Park, N. J.

MR. C. N. DUFFY, formerly treasurer of a number of street railway properties in St. Louis, has, it is reported, accepted a position in Chicago under Mr. D. G. Hamilton.

MR. H. R. FEHR, of Easton, Pa., has accepted the position of superintendent of the Easton, Palmer & Bethlehem Electric Railway. Mr. Fehr has been city engineer of Easton since 1891.

MR. BROOKS CLARKE, formerly connected with the Atlanta Consolidated Street Railway Company, Atlanta, Ga., is now with the Macon Consolidated Street Railway Company, Macon, Ga.

MR. WILLIAM B. GIVEN, receiver of the Pennsylvania Traction Company, of Lancaster, Pa., has been appointed a Commissioner from the State of Pennsylvania to the Paris Exposition of 1900.

MR. F. A. BARR has succeeded Mr. F. W. McClement as manager of the Winston-Salem Railway & Electric Company, of Winston, N. C. The property has recently passed into the hands of new owners.

MR. F. A. HUNTRESS, manager of the Halifax, N S., Tramway Company, has returned from a trip to the West Indies, where he has been looking over the field, with a view to securing street railway franchises.

MR. C. W. FOOTE has resigned the superintendency of the Zanesville Electric Railway, to take effect Sept. 1, and has accepted the general managership of the Cincinnati & Miami Valley Traction Company.

MR. JOHN C. DOLPH, general sales agent of the Sterling Varnish Company, returned Aug. 4 from a four months' trip to Europe, during which time he has largely extended the business of his company abroad.

MR. NATHAN E. CAPEN has been elected superintendent of the Easton, Palmer & Bethelehem Street Railway to succeed W. E. Cox, who resigned July 1. Mr. Capen was formerly assistant superintendent of the road.

MR. N. W. L. BROWN, superintendent of construction, Atlanta Railway & Power Company, Atlanta, Ga., has resigned this position, which he has held for many years, to go into the cotton seed oil business in Alabama.

MR. ISAAC L. RICE has been forced to resign his position as president of the Electric Storage Battery Company owing to pressure of other duties. He has been succeeded by former First Vice-President George H. Day.

MR. GARRETT A. HOBART, having sold his holdings in the Paterson (N. J.) Street Railway Company, has handed in his resignation as president of the company. It is understood that Mr. David Young will succeed him.

MR. R. F. FOX, general manager of the Wilmington, Del., City Railway Company, has resigned. Mr. Fox will be succeeded by Joseph C. Lugar, formerly superintendent of the Roxborough, Chestnut Hill & Norristown Railway Company, of Philadelphia.

MR. A. E. WORSWICK, chief engineer in charge of the construction of the Mexico City electric lines, in behalf of Wernher, Beit & Co., of London, arrived in New York, on Aug. 11, from Mexico, joining here Mr. W. B. Rommel, who arrived from London on Aug. 8.

CAPT. ROBERT McCULLOCH, who for many years was manager of the St. Louis street railway system, owned by the National Railway Company, of Chicago, has severed his connection with this system, and, it is announced, will accept a position at Chicago under Mr. D. G. Hamilton.

MR. H. C. BENAGH, who has been superintendent of the Savannah, Thunderbolt & Isle of Hope Railway Company, of Savannah, Ga., and who has left this position to go to Nashville, was presented on the eve of his departure with a handsome silver tea service of six pieces by his former employees.

MR. SALVADOR POTIS, for many years chief engineer of the West Chicago Street Railway Company, has recently been selected chief engineer of the Illinois Telephone Construction Company, and will have full charge of the work of laying conduits and installing exchanges; his local office being at 746 The Rookery, Chicago.

MR. W. J. JOHNSTON, formerly proprietor of the "Electrical World," left New York recently. He intends to make a tour around the world, spending some time in Hawaiian Islands, Japan, China, India, Egypt, etc., and a visit to Manila is also in his itinerary.

MR. A. K. BAYLOR has resigned his position with the British Thomson-Houston Company, but will be for some time yet to come in close touch with its management in completing various contracts which have been taken during his incumbency. Mr. Baylor is now in America, but will return to London early in September.

MR. WILLIAM C. WHITNEY has returned to New York after a six weeks vacation trip, where he appears to have regained his health completely. He states that while abroad he heard of the so-called strike on the Metropolitan system, but had no uneasiness about it, realizing the system was left in hands entirely competent to manage it.

MR. GEORGE E. PRATT, who has been representing for some time past the Ajax Metal Company, with headquarters at Philadelphia, is now connected with the Hubbard Brake Company, a new concern recently formed for the manufacture of an electric brake of novel design, and which is briefly described in another column of this issue.

MR. C. A. INGLE has resigned his position as general manager of the Taunton Street Railway Company, of Taunton, Mass. He has accepted a position with the Pratt & Whitney Machine Company, of Hartford, Conn. On the last day of his services with the old company Mr. Ingle was presented with a gold watch and chain by his former employees.

MR. H. S. KEMP has accepted the place of superintendent of maintenance with the Staten Island Electric Railroad Company, in place of Mr. J. H. Sims, resigned. Mr. Kemp held a similar position with this company, but resigned about a year ago to become Eastern representative for the Gold Car Heating Company, which position he now leaves to return to Staten Island.

MR. AUSTIN E. SMITH, manager, treasurer and director of the Springfield Street Railway Company, of Springfield, Mass., died very suddenly on Aug. 8. Mr. Smith has been connected with this company for over twelve years, having entered its employ first as cashier. He rapidly rose to positions of greater responsibility until at the time of his decease he held the three offices mentioned above.

MR. GEORGE A. THOMSON, who was formerly connected with the Short Electric Railway Company, the Forest City Electric Company and other well known Western concerns, has been appointed Eastern representative of the Adams-Bagnall Electric Company, the well-known arc lamp manufacturers, in place of C. W. Phipps, resigned, and is now established at the company's New York office, 222 Havemeyer Building.

MR. W. B. ROMMEL, engineer with Wernher, Beit & Co., of London, arrived in New York on Aug. 8, and remains here until about the middle of September. While in this country he will purchase apparatus and material for the electrical equipment of the Lisbon (Portugal) tramway. Mr. Rommel will reside in Lisbon for a period of three years or more, having undertaken the management of the Lisbon tramway system. He is accompanied on his American trip by Mrs. Rommel.

MR. H. H. VREELAND, president of the Metropolitan Street Railway Company, of New York City, on Aug. 12, gave the heads of departments of his system an outing on the grounds of the Tonetta Outing Club, near Brewsters, N. Y. The party arrived on special cars, and were taken in carriages to the club grounds at Tonetta Lake, where a clambake was prepared. A sail on the lake was followed by a drive of three miles to "Rest Awhile," the country home of Mr. Vreeland, where the party was received by Mrs. Vreeland and several young ladies. Luncheon was served on the piazza and lawn.

MR. CHARLES N. BLACK, who has been for several years connected with the Brush, Walker and Westinghouse interests, has retired from the service of the Westinghouse Company in order to engage with Ford, Bacon & Davis, the well known consulting engineers of New York city. Mr. Black is well known as one of the ablest designers of arc lighting machines in the country, one of his prominent achievements in this direction being the design of the 125-h.p. Brush arc machine, which has made a remarkable record throughout the country, and has been installed in large numbers in Brush stations. Mr. Black is a graduate of Princeton University, class of 1888.

MR. OSCAR T. CROSBY, who has been delayed in this country for several weeks longer than expected on account of the organization of the Washington Traction Company, sailed for England on the St. Louis Aug. 9. He will be at the Savoy Hotel, London, for some weeks, and will then travel quite extensively. He is particularly looking forward to an extended sojourn in Africa, where he may penetrate some of the regions rarely visited by tourists, including Abyssinia and the Soudan. It is Mr. Crosby's intention on returning to this country, six months or more hence, to devote his entire time to sociology and other studies in which he has long been interested.

MR. W. F. FURBECK, who has been long associated with Mr. Charles T. Yerkes in his street railway interests in Chicago, has resigned the position of private secretary to Mr. Yerkes, and will probably also resign all other positions he now holds with the street railway companies. Mr. Furbeck is a director and vice-president of the North Chicago Street Railway Company, vice-president of the Chicago Consolidated Traction Company and also a member of the executive board of the Lake Street Elevated Company. He intends to engage at once in the banking business.

DR. J. S. LAWRENCE, president of the Charleston Consolidated Railway, Gas & Electric Company, of Charleston, S. C., died at Capon Springs, W. Va., on Aug. 5. He had been ill for several months, and had recently returned from a trip to Europe in an unsuccessful effort to regain his health. Dr. Lawrence was a resident of Washington, D. C., for many years, until in 1896 he secured control of the horse car lines in Charleston, S. C., and converted them into a large and excellently equipped system, ranking among the best in the South. In 1897 he built the Charleston & Seashore Railroad and founded one of the largest amusement parks in the country on the Isle of Palms. These properties were both very successful financially, and in the early part of this year he consolidated all of the street railroad, gas and electric light properties.

MR. GEORGE HENRY WHEELER, formerly president of the Chicago City Railway Company, died very suddenly on Aug. 11, at Plattsburg, N. Y. Mr. Wheeler had been one of Chicago's leading business men for over forty years, and had been closely identified with several important local enterprises. He was born at La Porte, Ind., on August 1, 1841. He moved with his parents to Chicago in 1849, and his early education was obtained in the public schools of that city. After taking a college course at Racine, Wis., he returned to Chicago in 1860, and entered into business with his father. He became connected with the Chicago City Railway Company in 1891, and in that year was elected its president. He continued as the executive head of the entire system until about three years ago, when he was forced to retire by failing health. Mr. Wheeler was a member of the Chicago and Union League Clubs; also a prominent figure in the Board of Trade; a director in the World's Columbian Exposition in 1892-3, and a director of the Continental National Bank.

GEORGE HENRY WHEELER

MR. HENRY M. RANSOM, who is one of the youngest, yet one of the most popular and more successful salesmen, in the street railway industry, has left his position with the Consolidated Car Heating Company, to take the office of purchasing agent for the International Traction Company, of Buffalo. Mr. Ransom was born in 1870 in Albany, and was educated at the Albany Boys' Academy. He entered the employment of the Ransom Stove Company at the age of eighteen, and in 1893 held the position of shipping clerk. In that year he went with the Consolidated Car Heating Company, of Albany, representing that concern in the electrical branch of its business. At that time electrial heaters were practically unknown to roads in general, the Consolidated Company having its heaters on but four roads, operating from one to sixteen cars. At the present time in the territory alone just left by Mr. Ransom Consolidated heaters are used on over 200 roads, the total number of cars equipped being over 5000.

AMONG THE MANUFACTURERS

ROGER W. BABSON, banker and broker, of Worcester, Mass., is making a specialty of Massachusetts street railway bonds.

THE ELECTRIC STORAGE BATTERY COMPANY, of Philadelphia, has removed its New York office from 20 Broad Street to the fifteenth floor of the American Surety Building, 100 Broadway.

THE JOSEPH DIXON CRUCIBLE COMPANY, of Jersey City, is out with another handsome brochure, finished in colors, describing graphite and its uses. Graphite makes an excellent lubricant for engine bearings and valves.

THE AMERICAN ELECTRICAL WORKS, of Providence, R. I., is sending out invitations for its annual clam bake. The invitations are engraved on thin sheets of copper, and announce that the twenty-first annual clam dinner will be held at Pomham Club, on Saturday, Sept. 9, 1899.

THE PACKARD ELECTRIC COMPANY, of Warren, Ohio, the well-known manufacturers of incandescent lamps and transformers, announce that Messrs. Mayer & Englund, of 10 South Tenth Street, Philadelphia, Pa., have taken the agency for its incandescent lamps for the street railway field.

THE ELECTRIC STORAGE BATTERY COMPANY, of Philadelphia, announces by card that its New York office has been removed to the American Surety Building, 100 Broadway. At the bottom of the card announcing the change is the very significant statement: "160,000-h.p. hours are stored daily in chloride accumulators."

THE AMERICAN ENGINE COMPANY, of Bound Brook, N. J., has just received an order from the Hollingsworth & Whitney Company, of Waterville, Maine, for the entire engine equipment of its new mill, consisting of two special 300-h.p. double engines and a 125-h.p. engine, and also a complete 75-kw. electric generating plant.

THE LORAIN STEEL COMPANY, through its Chicago representatives, Littlefield & Mysenburg, has secured the order for 100 Dupont trucks for the Indianapolis Street Railway Company, at Indianapolis, Ind. The western agents report that this truck is becoming more and more popular and that business in the western territory is extremely promising.

THE EDWARD P. ALLIS COMPANY, of Milwaukee, Wis., describes recent improvements in its well-known system of engines in a handsomely prepared pamphlet of 183 pages. The more prominent types of its latest horizontal and vertical engines are shown in full page engravings. To purchasers of apparatus for power plant the catalogue will be of great value.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY'S bulletin, No. 2734, for August, is devoted to "Bullock Engine Type Generators." These are designed to meet the demand for a slow rotative speed machine for direct connection to either steam or gas engines or water wheels. Any one interested in apparatus of this kind should send for this August bulletin.

MARLIN & COMPANY, Inc., of Pittsburgh, Pa., are receiving a rush of orders for their specialties consisting of exhaust heads and pipes, portable tanks for storage of oil, ice cans, filters, cornices and skylights, etc. The Marlin exhaust head especially is receiving attention from steam engineers and is being sold in all parts of the country. This apparatus was fully described in the Street Railway Journal for April, 1899.

THE CENTRAL ELECTRIC COMPANY, of Chicago, has just received a heavy stock of the Standard trolley wheels as made by the Central Union Brass Company. These wheels are finely finished, ample in size and are claimed to give lasting service from fact of excellent metal used in their construction, combined with the peculiar arrangement of strengthening webs. Easy running is secured by use of the best grade of graphite bushings.

THE BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., has the contract for erecting the new car barn for the New Bedford, Middleboro & Brockton Railway Company. In connection with the car barn there will be an engine and boiler room of the same construction. The Syracuse Construction Company has also placed the order for its bridge over the D. L. & W. R. R. at Syracuse, N. Y., with the Berlin Iron Bridge Company.

LEONHARDT WAGON MANUFACTURING COMPANY, of Baltimore, Md., reports that it never has been so busy as during the last seven months in building its special lines of tower and emergency wagons, both for foreign and domestic orders. These wagons are growing steadily in favor with the trolley lines in all sections of the globe, as is demonstrated by receipts of duplicate orders and the complimentary testimonials sent in unsolicited.

GEORGE W. LORD, of Philadelphia, the manufacturer of Lord's boiler clensing compound for reducing scale, is running his factory to its fullest capacity to keep up with orders in hand. These compounds are being rapidly introduced in various countries as well as in the United States. Among recent orders is one from Brazil for 10 tons, this being the third order from the same party. Mr. Lord would be pleased to correspond with any one having trouble with their boilers from scale or other causes.

ROBERT H. DERRAH, of Boston, the well known expert in arranging trolley excursions, is meeting with great success in his new venture in Boston. Mr. Derrah makes arrangements with the different street railway companies in suburban Boston for running special excursion cars three or four times a week, and these have been very well patronized. On these tours everything is done to make the excursionists comfortable, and they are relieved of all care or anxiety regarding connections, refreshments, etc.

ELMER P. MORRIS & COMPANY, of New York, in line with their policy to add to their list of agencies, the best materials in the street railway field, have made arrangements for handling the products of the Wagenhals Manufacturing Company, of Cincinnati; the Mundel Electric Works, of Springfield, and the Spiral Journal Bearing Company, of St. Louis. Mr. Morris reports a very heavy business during the past month, the demand for poles and bonds being especially good. Several large orders from foreign countries have also been filled.

THE BUFFALO FORGE COMPANY, of Buffalo, N. Y., has published a pocket edition of its general catalogue describing the many specialties handled by this concern. These include horizontal and upright steam engines, mechanical draft, heating, ventilating and drying fans and apparatus, blowers and exhausters, blacksmith drills, punches, shears and cutters, stationary, portable and heating forges, etc. The book contains over 398 pages, and its value is greatly increased by the numerous cuts which are given in conjunction with the descriptive matter.

THE CHARLES SCOTT SPRING COMPANY, of Philadelphia, whose works were destroyed by fire a few months ago, has been hard at work completing a new factory, and announce that this is now rapidly nearing completion. Additional ground has been added to the spring plant, covering about 55 ft. x 155 ft. A new machine house, 35 ft. x 200 ft., has also been built. With these increased facilities the company will be better able to supply its well known line of flat and spiral springs than ever before, and an excellent business is expected during the coming months.

FRED. M. LOCKE, of Victor, N. Y., manufacturer of the well known Locke insulator, has been successful in his legal controversy over the validity of his patents. Mr. Locke filed his application for letters patent in February, 1897, and on August of the same year, Mr. Boch, of the R. Thomas & Sons' Company, East Liverpool, Ohio, filed an application for the same thing. Interference proceedings have been pending since September, 1897, but the Patent Office has just decided that Mr. Locke was the first to conceive and reduce to practice the invention in issue.

THE BABCOCK & WILCOX COMPANY, of New York, has sold to the Manhattan Elevated Railway Company, of New York city, the boilers required for its new electric generating plant, which will furnish electric current for operating its entire elevated railway system in New York city. The boiler equipment will consist of sixty-four 520-h.p. Babcock & Wilcox all wrought steel boilers, capable of carrying a working pressure of 200 lbs. per sq. in. The boilers will be fitted with Roney automatic stokers, manufactured by Westinghouse, Church, Kerr & Company. This is the largest single order ever placed for stationary boilers.

THE large increase in English orders that has come to the Bullock Electric Manufacturing Company, has necessitated the sending of B. W. Spellmire, the company's engineer of tests, to the London headquarters of the company. Mr. Spellmire will superintend the installations of Bullock machines in the territory mentioned, the first installation being in the large printing establishment of Cassell & Company, London; the Nottingham "Guardian," Nottingham; Birmingham "Daily Post," Birmingham; Manchester "Evening Chronicle," Manchester, and the Belfast "Evening News," Belfast.

AMONG RECENT ORDERS received by the Ridgway Dynamo & Engine Company for McEwen engines and Thompson-Ryan generators, are three 75-h.p. tandem compound engines direct connected to three 50-kw. generators, purchased by the Treasury Department for lighting the United States Court House and Post Office Building at Cincinnati, Ohio; two 250-h.p. engines direct connected to two 150-kw. generators for the Berwind-White Coal Mining Company, Philadelphia, Pa., for its mining operations at Windber, Pa. This will make a total of fourteen engines and ten generators of this make installed by these same people at Windber, Pa., within the last two years.

THE GOLD CAR HEATING COMPANY AND THE GOLD STREET CAR HEATING COMPANY, of New York, report that the number of orders which they have taken during the past few months are of such magnitude as to surpass all their former records. It is a certainty that the improved Gold electric heaters have struck a popular cord among railway officials. Prominent among the orders for electric heaters which have been taken recently is one from the Boston Elevated Railway Company, formerly the West End Street Railway Company, of Boston, which has awarded the contract for electric heaters for its 100 new cars to the Gold Car Heating Company.

WILBUR B. DRIVER & COMPANY, of New York, have published for the convenience of the engineering trade a neat booklet containing valuable resistance and capacity tables for "Climax" resistance wire. It is claimed that this wire has forty-eight times the resistance of copper, while German silver has only sixteen times and ordinary steel wire about eight times the resistance of copper wire of the same diameter. Its low temperature coefficient fits it for any use to which German silver can be applied, and its high specific resistance renders it an economical substitute. Its chemical properties make it available for rheostat work where German silver is useless on account of its brittleness caused by heating and cooling.

WESTINGHOUSE, CHURCH, KERR & COMPANY, of New York, deserve the credit for producing one of the most artistic catalogues of the season. This is printed on the finest of tinted paper, and the pages are illustrated wih artistic drawings of private residences and hotels where electric lighting is provided by the Westinghouse Company's engines and generators. The catalogue is published with the view of calling attention to what has been accomplished by the Westinghouse Company in the way of electric light and power installations in hotels, private residences, etc. A number of the installations include apparatus for lighting houses, stables and grounds, and also for furnishing power to operate pumps, elevators, ventilating fans, ice cream freezers, dairies, laundries, etc.

ONE OF THE MOST VALUABLE points relating to the use of belts is not often enough realized, or, at best not emphasized; this is the fact that the more belt surface running in contact with the pulley the more power there is transmitted by the belt. In running a belt tight only about half of the pulley surface is in contact with the belt, therefore if a belt can be made to run without slipping it can be run slack and much power will be gained. The Cling-Surface Manufacturing Company, of Buffalo, N. Y., reports that it is adding scores of belts every week to the number already running slack through the use of Cling-Surface, and of the daily letters received acknowledging this, one from Alhambra, Cal., says: "After thoroughly testing Cling-Surface I find that I can run with a slack belt and get more power by far than I could with a tight belt before using Cling-Surface."

WENDELL & MACDUFFIE, of New York, general supply agents, have received orders since the first of August for fifty

snow plows and sweepers, as follows: Twenty-two plows to the Boston Elevated Road; five plows to the Brooklyn Heights Railroad Company; eleven sweepers and one plow to the North Jersey Street Railroad Company; five plows to the Bridgeport Traction Company; eight plows to other roads. This firm is doing an extraordinary business in this line this year, and orders are being placed much earlier than usual. This is accounted for by the fact that some of the roads were caught short of snow equipment last year. The above orders will tax the capacity of the Taunton Locomotive Manufacturing Company, who are the manufacturers of the above plows and sweepers, and railroad managers would do well to place their orders at once if they contemplate purchasing snow equipment.

THE STAR BRASS WORKS, of Kalamazoo, Mich., manufacturers of the Kalamazoo long distance trolley wheel, are meeting with marked success in the sale of their wheels and harps. The demand has been so great that they have been compelled to more than double their facilities within the past year, and have increased their capital stock from $10,000 to $20,000. The increased orders from the leading roads of the country, together with the additional new business must certainly be very gratifying to them. The company's officials credit their success to the fact that they aim to manufacture a superior article, judiciously advertise it and secure only the most capable salesmen to handle their goods. The Western Electrical Supply Company, of St. Louis, Mo., is their western and southwestern representative, the home company handling the north and east exclusively.

THE HARRISON SAFETY BOILER WORKS, of Philadelphia, report recent sales of Cochrane feed-water heaters and purifiers as follows: Bethlehem (Pa.) Steel Company, 12,000 h.p.; Pennsylvania Light & Power Manufacturing Company, Phila., 3000 h.p.; Waterbury Rope Company, New York, 850 h.p.; Durham Iron Works, Riegelsville, Pa., 600 h.p.; Blodgett Estate, Boston, 300 h.p., special; Thorley Building (Pabst Brewing Company), New York, 300 h.p.; Pittsburgh (Pa.) Brewing Company, 600 h.p.; E. P. Allis Company, Milwaukee, Wis., 200 h.p.; American Nut & Bolt Works, Cleveland, Ohio, 350 h.p.; Peoples Independent Rice Mill Company, Crowley, La., 350 h.p.; Plaza Hotel, New York, 300 h.p., special; International Paper Company, Franklin Falls, N. H., 350 h.p.; Providence (R. I.) Machine Company, 250 h.p.; Lorain (Ohio) Street Railway Company, 850 h.p.; Warden Power Building, Phila., 1000 h.p. Many orders for Cochrane separators have also been received.

THE PROVIDENCE ENGINEERING WORKS, of Providence, R. I., has recently acquired the entire equipment and business of the Providence Steam Engine Company as well as the domestic business of the Rice & Sargent Engine Company. The works of the company occupy the block bounded by South Main, Pike, South Water and Bridge Streets, with water frontage on the Providence River, and are amply equipped with cranes, tools and other facilities for turning out its product with promptness and of the highest degree of excellence. The shop methods in use are based upon the highest American standards, and include not only extensive use of gages, jigs and fixtures, but a rigid system of inspection of work. The business of the new company consists of the manufacture of the Rice & Sargent engine and the improved Greene engine, for both of which it is the sole builder. The design and construction of general machinery will also be engaged in. The officers of the company are as follows: R. A. Robertson, president; W. Fred Reynolds, vice-president; Richard H. Rice, treasurer.

AMONG the recent orders received by Broomell, Schmidt & Company, Ltd., York, Pa., manufacturers of the American Fuel Economizer, are the following: For Hillingsworth & Whitney Company, Waterville, Mo., two large economizers, two induced draft fans, with 14 ft. wheels, direct-connected engines, together with about 150,000 lbs. of steel smoke breechings, dampers, stacks, etc.; Iukens Iron & Steel Company, Coatesville, Pa., two American fuel economizers, two induced draft fans, with 12-ft. wheels and direct-connected engines, also about 80,000 lbs. of smoke breechings, dampers and connections; Weston Electrical Instrument Company, Newark, N. J., for the power house of its new works at Waverly, two American fuel economizers, with metallic casing, connections, etc.; Vacuum Oil Company, Rochester, N. Y. (third order), one American fuel economizer for utilizing waste heat from oil stills; Monterey Electric Light Company, Monterey, Mexico, one American fuel economizer complete, with metallic casing, induced drafts, fans, etc. The York Light, Heat & Power Company, York, Pa, has closed a contract with Broomell, Schmidt & Co., Ltd., for two 250-h.p. American water-tube boilers complete, with induced-draft fans, settings, etc.

AMONG the more important sales made by the Bullock Electric Manufacturing Company, of Cincinnati, during July, are the following: Union Depot, Dayton, Ohio, two 50-kw. engine type generators; Fuller Construction Company, New York city, four 50-kw. engine type generators; Wilson Aluminum Company, Holcomb Rock, Va., one 60-kw. belted generator; Warren K. Blodgett, Boston, Mass., one 150-kw. belted generator; American Type Foundry Company, Cincinnati, Ohio, twenty-five slow speed motors for direct connection to type machine; D. E. Whiton Machine Company, New London, Conn., one 30-kw. belted generator; United States Government, San Francisco, Cal., one 30-kw. belted generator; Pullman Palace Car Company, St. Louis, Mo., one 12½-kw. belted generator, one 25-kw. engine type generator; "Daily Mail," London, Eng., two 50-h.p. printing press equipments, Bullock "Teaser Control System;" Aldrich Mining Company, Brilliant, Ala., one 30-kw. belted generator; Missouri Lead & Zinc Company, Joplin, Mo., one 20-h.p. motor; Boston News Bureau, Boston, Mass., one 9-h.p. belted motor, 900 r.p.m.; Hanover Manufacturing Company, Bethlehem, Pa., one 10-h.p. belted motor; Southern Electric Company, St. Louis, Mo., one 12½-kw. belted generator; Vulcan Metal Refinery Company, Sewaren, N. J., one 17½-kw. belted generator.

THE McGUIRE MANUFACTURING COMPANY, of Chicago, is working to its full capacity, particularly in the snow sweeper and car heating departments. It has just secured contract for sixty of its No. 39 double trucks for the San Francisco & San Mateo Railway, of San Francisco, Cal., this being the entire equipment. It is now delivering the 300 trucks for the Northwestern Elevated Railway Company, of Chicago. It also has orders from the Toledo Traction Company, Toledo, Ohio; Central Railway Company, Peoria, Ill.; Consolidated Traction Company, Pittsburgh, Pa.; Rochester Railway Company, Rochester, N. Y.; Monongahela Street Railway Company, Pittsburgh, Pa.; Madison Electric Railway Company, Madison, Wis.; Cripple Creek District Railway Company, Cripple Creek, Col.; Suburban Rapid Transit Company, Pittsburgh, Pa.; South Bend Street Railway Company, South Bend, Ind.; Peoria & Pekin Terminal Railway, Peoria, Ill.; Chicago City Railway Company, Chicago; W. L. Mellon, Pittsburgh, Pa.; Black River Traction Company, Watertown, N. Y.; Metropolitan Street Railway Company, Kansas City, Mo.; Indiana Railway Company, South Bend, Ind.; Canadian General Electric Company, Toronto, Ont.; Star Electric Company, Dubuque, Ia.; Bethlehem & Nazareth Passenger Railway Company, Nazareth, Pa.; St. Joseph & Benton Harbor Electric Railway Company, St. Joseph, Mich.; Tacoma Railway & Power Company, Tacoma, Wash.; Metropolitan Street Railway Company, New York, N. Y.

New Publications

Granite State Scenery In and About the Capital City. Published by the Concord Street Railway Company, Concord, N. H.

This is a very tasteful book of views, larger than is usually attempted by the street railway companies, and it gives a large number of very tasteful illustrations of the city of Concord. It is issued, of course, to interest citizens of and visitors to that city in the features of interest about it, and is written and published in a most attractive way.

Trade Catalogues

Engine Catalogue. Published by Edward P. Allis Company, Milwaukee, Wis. 184 pages. Illustrated.

Resistance Wires. Published by Wilbur B. Driver & Company, New York city. 16 pages. Illustrated.

VOL. XV. NEW YORK AND CHICAGO, OCTOBER, 1899. No. 10.

ELECTRIC RAILWAY PRACTICE IN AMERICA AS EXEMPLIFIED IN CHICAGO

For good or ill, whether profitably or unprofitably, America has been forced to be a pioneer in the science of municipal transportation, and to bear the burden of experiments in every stage of development. The first passenger horse railway in the world was run in New York City, the first cable railway in San Francisco, and the first important commercial electric railway in Richmond. Many millions—measured in francs, dollars or pounds sterling, as you will—have been lavishly poured out on more or less promising schemes, only to find place eventually in the "profit and loss," or "experience" accounts.

It follows, therefore, that there is no such thing as a universal, well digested electric railway practice in America. Instead of this, all grades of intelligence are found represented in our existing city railways, from the broken down relics of early days, which may be run across occasionally even yet, to the best and most recently built systems, employing every material and labor saving device known. While there is much to learn from the older electric railways as to ways of "making the best of a bad bargain," it is the latest and best practice only which is worth description and analysis for the benefit of those who have

A LIGHT HOUR IN THE CONGESTED DISTRICT OF CHICAGO

now before them the problem of building and equipping new railways. It may be useful, therefore, before describing Chicago construction, in some respects excellent, in others not wholly not up to date, to take a broad survey of American experience as so far developed and briefly explain the latest and best practice used in American roads now building.

MOTIVE POWERS

Horse railways have almost disappeared in America, the only remaining examples being in one or two of the largest cities, such as New York and Chicago, where rights for electrical equipment have been for a long time denied or restricted, and in a few small towns and villages, where traffic has not seemed to warrant the cost of electrical equipment, so that horse cars have been continued almost as private stage or omnibus lines might be, frequently owned by an individual and run as a strictly private enterprise.

The cable system has been blasted out of the streets in all except three or four cities, in which it is also doomed, and where steps have already been taken to replace it with electric traction. The reasons for this are too well known to require repetition here.

Compressed air cars are now in regular operation on the Twenty-eighth and Twenty-ninth Streets line in New York City, the largest installation yet made in America, and the most carefully worked out in detail. So far, they appear to be giving excellent satisfaction to the public, and while they have been running for too short a time to determine the cost of operation, it is believed that they have some place in modern street railroading. Other experiments in compressed air are being made in Chicago, but without well defined results as yet.

More or less extensive experiments are also being made with stored steam motors, gasoline motors, and one or two other types of motive power involving reciprocating motion machinery, and it seems not impossible to hope that some of these, too, will find a place perhaps, in small towns or villages or on long distance interurban lines where car service is infrequent and the expense of power station installations would be too great a burden. Inventors of these systems are seriously handicapped by the disinclination of street railway managers to look into their merits carefully, owing to the strong hold which electric traction has upon the imagination, and the well nigh universal testimony to its merits.

Electric traction is now almost universal in America, over 90 per cent of the entire street railway mileage being equipped with this motive power. The overhead wire system is most generally used, the underground conduit having been adopted only in New York City and Washington, where climatic conditions are favorable, and where the city sewerage systems—an absolute necessity for successful operation of an underground conduit system—are good. So far there has been no serious agitation elsewhere for the adoption of the underground conduit, but the overhead wire system is considered by the municipalities as satisfactory and as having a number of advantages over any other form which will compensate for the slight disfigurement of the streets. There is but one important storage battery installation made in America, that on the lines of the Chicago Electric Traction Company, where twenty-five cars have been running over 25 miles of track for about two years with fairly satisfactory results. *

CROSSING OF AN ELEVATED RAILWAY, A STEAM SUBURBAN RAILROAD AND A SURFACE LINE

For heavy electric railroading at high speeds, the third-rail conductor has come into quite general use as affording a better means of getting the current from the power station to the cars than is the overhead wire. Various methods of sectionalizing the third rail in such a way as to avoid danger from shocks have been devised, but have not yet been put into operation on a large scale.

The "surface contact," or "button system" of electric
